We studied the correlation between shift in recombination zone and efficiency roll-off in typical PHOLED based on the archetypical 4,4'-bis(carbazol-9-yl)biphenyl (CBP) and Tris(2-phenylpyridine)iridium(III) [Ir(ppy)3] host-guest system. To probe the shift in recombination zone, electroluminescence (EL) spectra of devices with various architectures at different current densities are studied. Results show that increase of current density shifts the recombination zone from the emission layer (EML)/electron transport layer (ETL) interface toward the hole transport layer (HTL)/EML interface. Results from the delayed electroluminescence intensity suggest that Host-Host Triplet-Triplet Annihilation (TTA) mostly occurs at the region close to the EML/ETL interface implying a presence of large number of host excitons. On the other hand, Host-Host TTA is insignificant at the HTL/EML interface implying a reduction of host excitons at the vicinity of this interface. The Results further imply that the luminance at low current density mostly originates from the e-h recombination on the host followed by energy transfer to the guest and at high current density direct e-h recombination on the guest is the main emission mechanism. The results suggest that the shift in recombination zone and subsequent change in emission mechanism plays a major role on the efficiency roll-off.

Hexaazatriphenylene-Hexanitrile (HATCN) as an anode buffer layer for high performance transparent inverted OLEDs

Jeong-Hwan Lee, Sunghun Lee, Jungbum Kim, Junhyuk Jang, Hyo Jung Kim, Jang-Joo Kim, Seoul National Univ. (Korea, Republic of)

We employed 1,4,5,8,9,11-hexaazatriphenylenehexacarbonitrile (HATCN) as an anodic buffer layer between the active layer and the indium zinc oxide (IZO) top electrode and demonstrated a high performance inverted transparent OLED. HATCN, a discoid organic molecule possessing a deep lowest unoccupied molecular orbital (LUMO) level, good hole injection characteristics, low refractive index of about 1.7 in the visible wavelength and very high stability even in ambient air conditions, is thermally evaporated at low temperature below 300oC in vacuum. The device showed a total maximum luminance and a power efficiency of 67 cd/A and 67 lm/W, respectively, when the emitted lights through both the bottom and top sides are summed, and this is almost double the efficiency compared to the best values reported up to now in transparent OLEDs, to the best of our knowledge. The experimental data showed excellent agreement with the optical simulation results based on the classical electromagnetic theory with a full vectorial approach. The fact indicates that HATCN not only perfectly protects the organic active layers from sputtering bombardment, but also acts as a good hole injection layer even after sputter bombardment. Based on the x-ray and atomic force microscopy measurements, it was confirmed that the molecular alignment and nanostructure of HATCN thin films stacked with a (00l) hex preferred orientation on organic surfaces and the orientation was maintained even after deposition of the IZO electrode. Moreover, the inverted OLEDs showed the best transmittance reported up to now with an average transmittance of 81% in the visible spectrum range.

8830-1, Session 1

Design and synthesis of small molecules for the fabrication of high efficiency solar cells *(Keynote Presentation)*

Guillermo C. Bazan, Univ. of California, Santa Barbara (United States)

High charge separation efficiency combined with the reduced fabrication costs associated with solution processing and the potential for implementation on flexible substrates make "plastic" solar cells a compelling option for the next generation of photovoltaic devices. The control the donor/acceptor blend morphology in bulk heterojunction materials as required for achieving high power conversion efficiency is therefore of primary concern. We showed that by incorporating a few volume percent of high boiling point solvent additive, the power conversion efficiency of photovoltaic cells (AM 1.5 conditions) is substantially increased, and this method of optimization is now the most widely used processing option for polymeric systems.

Previous examination of the active layers has shown that the additives influence the size of the domains within the bulk heterojunction (BHJ) organization and can improve the order within the polymer domains. In the first part of this presentation, we disclose in-situ grazing incidence wide-angle x-ray scattering as a function of time to explore the dynamics of the BHJ evolution. These studies show that a small percentage of octanedithiol in chlorobenzene induces the nucleation of polymeric crystallites within two minutes of deposition, increases the orientational order of specific polymorphs, and allows further crystallite nucleation over a period longer than 40 minutes after casting. These observations are absent when the same BHJ blend is cast from pure chlorobenzene.

In the second part, we will examine a new class of small molecules with modular features that can be used to fine tune the optical absorption to match the solar spectrum, molecular orbital energies that are appropriate to achieve excellent power conversion efficiencies and topological attributes for controlling phase separation and film forming behavior. Through appropriate processing conditions involving very small quantities of solvent additives, it is possible to attain power conversion efficiencies of 7 %. The additive content is critical for managing the crystallite size of the donor domains.

8830-2, Session 1

Novel thiophene-based materials for highly efficient small molecule organic solar cells *(Invited Paper)*

Peter Baeuerle, Amaresh Mishra, Gisela Schulz, Roland Fitzner, Univ. Ulm (Germany)

Oligothiophenes represent an important class of compounds in the field of organic materials and have successfully been used as active components in organic solar cells (OSC).

On the basis of oligothiophenes, we are currently synthesizing and investigating novel organic semiconductors, which are applied in various types of organic solar cells. In this respect, terminally acceptor-substituted oligothiophenes have been further developed and tuned with respect to their electrooptical and self-organization properties. Efficiencies in vacuum-processed small molecule organic solar cells could be recently increased to (record) values of 7.2% for single junction and 12.0% for multi-stack cells. X-ray structure analyses guide the understanding how intermolecular interactions in the bulk correlate with device performance.

Systematic structural variation of the basic oligomers allowed for their use in solution-processed bulk-heterojunction solar cells achieving efficiencies of over 5%.

8830-3, Session 1

Cruciform and H-shaped small molecules for organic solar cells *(Invited Paper)*

Peter J. Skabara, Anto R. Inigo, Sasikumar Arumugam, Alexander L. Kanibolotsky, Iain A Wright, Ewan Cameron, Univ. of Strathclyde (United Kingdom)

A series of hybrid tetrathiafulvalene-oligothiophene compounds has been synthesized, where the tetrathiafulvalene unit is fused at each side to an end-capped oligothiophene chain of varying length. Each hybrid structure (1-3) has been studied by cyclic voltammetry and UV-vis spectroelectrochemistry, with the results for the smaller analogues (1 and 2) used to provide an explanation for the processes involved in septithiophene analogue 3. Further comparison is made to the corresponding half units, which lack the fulvalene core and contain just one oligothiophene chain, where appropriate. Finally, the hole mobility of quinquithiophene-TTF 2 was calculated from field effect transistor characteristics and its surface morphology was characterised by tapping mode atomic force microscopy. Compound 2 has been identified as the material with the best performance in BHJ OPV devices using C71PCBM as the electron acceptor. The device characteristics will be reported.

8830-4, Session 1

Design of molecular donors for organic solar cells *(Invited Paper)*

Philippe Blanchard, Jean C. Roncali, Univ. d'Angers (France)

Organic solar cells (OSCs) offer the possibility to develop low-cost and lightweight sources of photovoltaic electrical energy by means of simple technologies with low environmental impact.

Until now, the most efficient OSCs have been based on the heterojunction formed at the interface between an electron donor material an electron acceptor. Whereas a large part of the OSCs developed so far have used soluble π-conjugated (co)polymers as donor material, the polydispersity inherent to polymers can result in problems related to the reproducibility of the synthesis, purification and hence composition and electronic properties of the donor material. This context has contributed to stimulate intensive research work focused on the development of donor materials based on perfectly structurally defined conjugated molecules.

During the past few years, a huge number of molecular donors have been synthesized and evaluated in OSCs. Although this research effort has generated important progress in device efficiency, many molecular donors, especially those used in solution-processed OSCs are rather complex molecular structures of high molecular weight obtained by multi-step syntheses.

In this presentation the relationships between the molecular structure and the photovoltaic performances of various classes of donor materials based on push-pull molecules will be discussed. Special emphasis will be placed on the molecular design of materials combining structural simplicity, low molecular weight and synthetic accessibility, all factors that are believed to acquire a growing importance in the future context of industrial large-scale production of OSCs.

8830-5, Session 2

Vapor printed organic electrodes and semiconductors *(Invited Paper)*

Karen K. Gleason, Massachusetts Institute of Technology (United States)

Vapor printing has emerged as a promising technology for creating patterned layers of conducting and semiconducting conjugated polymers in a single step from their monomer vapors. Conformal polymer films over rough, low-cost substrates can be achieved at low processing temperatures. Additionally, vapor printing method removes the need to consider the effects of solubility or dewetting for materials integration into organic photovoltaics. Vapor printed poly(ethylenedioxythiophene) (PEDOT) is comprised only of earth-abundant elements and represents a low cost, flexible alternative to ITO. Organic photovoltaic cells with vapor printed PEDOT fabricated directly on unmodified paper substrates have achieved power conversion efficiencies > 2%. Post-deposition acid rinsing improves the ratio of dc to optical conductivity to 12. The stability also improves. Dopant exchange occurs with the acid anions leads to a higher degree of doping and enhances the stability of electrical conductivity. Additionally, unsubstituted polythiophene(PT) and poly(isothianaphthene) (PITN), which are insoluble and infusible, and thus typically difficult to process, have been vapor printed. The dedoped PT displays semiconducting behavior with an optical band bap of ~2 eV, while the bandgap for PITN is ~ 1 eV. Integration of these donor layers into photovoltaic devices will be demonstrated.

(submission invited by Dr. Paul Lane)

8830-6, Session 2

Heterogeneity and nano-scale electrical properties of ZnO thin film electron-selective interlayers in organic photovoltaic devices

Gordon A. MacDonald, The Univ. of Arizona (United States); Rajiv Giridharagopal, Univ. of Washington (United States); Micheal W. Liao, Xerxes K. Steirer, Kai-Lin Ou, The Univ. of Arizona (United States); Guozheng Shao, David S. Ginger, Univ. of Washington (United States); Neal R. Armstrong, The Univ. of Arizona (United States)

Efficient charge harvesting in organic solar cells (OPVs) is critically dependent upon the energetics of the contact/active layer interface(s), and the heterogeneity in composition, on sub-micron length scales, which can lead to localized recombination and loss of device performance. Conducting tip AFM (cAFM) and Scanning Kelvin Probe Microscopy (SKPM) techniques are uniquely suited to the study of electrical property heterogeneity in contact materials, such as ITO, and in the interlayer films which are often added to the contact to impart hole (e.g. NiOx) or electron selectivity (e.g. ZnO or TiO2). This presentation focuses on the role that compositional and electrical property heterogeneity can play in ZnO interlayer films, as revealed by scanning probe techniques, correlated with overall device performance. Sputter-deposited ZnO (spZnO) films were created at a variety of oxygen partial pressures, which varies both the mid-gap defect density in the ZnO film, and its conductivity (series resistance). Mild acid etching of these ZnO films was used to reveal the presence of different crystal faces of the wurtzite lattice in spZnO films, which possess different effective work functions – leading to different barriers to charge harvesting and quite heterogeneous electrical activity revealed by cAFM. We correlate this heterogeneity with changes in device performance and demonstrate the importance of minimizing this heterogeneity in a variety of ZnO or TIO2 films, whether they are deposited in vacuum or solution processed for scalable OPV applications.

8830-7, Session 2

The influence of contact properties on device performance in organic solar cells *(Invited Paper)*

Dana C. Olson, National Renewable Energy Lab. (United States)

Organic photovoltaics (OPVs) have become an attractive technology that offer a lower cost alternative to current commercial solar conversion technologies due to their potential for low temperature, large-area, and high-throughput manufacturing. Further barriers that must be overcome prior to commercialization lie in the development of OPV materials and device architectures to result in improved efficiency and stability. To achieve this, we are developing unique tools, design rules, and new materials for both active layers and selective contacts.

While the active layer materials are important for determining the ultimate performance, interfacial contact layers must be optimized both electronically and chemically for new active layer components. Such interfacial contacts are believed to improve device performance by a variety of mechanisms such as improved energy level alignment and charge carrier selectivity leading to improved charge extraction and reduced recombination. We are investigating the influence of the electronic properties of electron and hole transport layer (ETL and HTL) contacts on device performance to gain a greater understanding of the relative contributions of contact properties such as work function and band alignment. In addition, we are studying the effects of interfacial chemistry on local band alignment and device performance, by showing the deleterious effects of protonation in high performance solution processed small molecule solar cells. The independent control of work function and band alignment is shown to result in increased performance in both standard and inverted device architectures. Through this approach we are able to actively tune the contact properties to the ever changing properties of new active layer materials.

We gratefully acknowledge funding from U.S. Department of Energy under Contract No. DOE-AC36-08GO28308 with the National Renewable Energy Laboratory for OPV device development as well as the Center for Interface Science: Solar Energy Materials (CIS:SEM) and the Center for Energy Efficient Materials (CEEM), Energy Frontier Research Centers Funded by the U.S. Department of Energy, Office of Basic Sciences, under Award Numbers DE-SC0001084 and DE-DC0001009, respectively.

8830-8, Session 2

High efficiency small molecular organic photovoltaic devices employing dual anode interfacial layers

Tyler Fleetham, Barry P. O'Brien, Arizona State Univ. (United States); John P. Mudrick, Univ. of Florida (United States); Jian Li, Arizona State Univ. (United States); Jiangeng Xue, Univ. of Florida (United States)

We demonstrated highly efficient small molecule organic photovoltaic devices using dual organic interfacial layers between the ITO anode and the organic donor material. The interfacial layers were composed of a spun-coat layer of poly(3,4-ethylenedioxythiophene): poly(styrenesulfonate) (PEDOT:PSS) followed by a small molecule organic layer of tetracene. The use of a small molecular templating layer, such as tetracene, proved to increase the molecular stacking of the subsequent phthalocyanine (Pc) based donor materials indicated by enhanced absorption in the region attributed to Pc aggregates, as well as increased crystalline domain sizes observed through AFM. Furthermore, the use of a PEDOT:PSS layer between ITO and a tetracene templating layer resulted in a change of the tetracene growth mode from a rough three-dimentional growth mode to a smooth, planar, two-dimensional growth mode that is better served for templating the active donor layer.

Upon application in planar heterojunction devices of PdPc and C60, an enhancement of over 80 percent in the donor contribution to the external quantum efficiency was observed. This enhancement has been attributed to the combination of exciton blocking by the higher bandgap tetracene layer, increased optical absorption, and enhanced exciton diffusion and charge transport resulting from the increased crystallinity. Furthermore, using a system of ZnPc as the donor material and C60 as the acceptor material, we fabricated planar-mixed heterojunctions with a PEDOT:PSS/ Tetracene dual anode interfacial layer. As a result we are able to fabricate devices with high JSC while maintaining a high FF and achieving power conversion efficiencies as high as 5.8%.

8830-9, Session 2

Polymer surface modification to produce low-work function electrodes for single- and multi-junction organic solar cells *(Invited Paper)*

Yinhua Zhou, Canek Fuentes-Hernandez, Jae Won Shim, Georgia Institute of Technology (United States); Jens Meyer, Princeton Univ. (United States); Anthony J. Giordano, Hong Li, Paul Winget, Theodoros Papadopoulos, Hyeunseok Cheun, Jungbae Kim, Georgia Institute of Technology (United States); Mathieu Fenoll, Georgia Institute of Technology (United States) and Solvay S.A. (Belgium); Amir Dindar, Princeton Univ. (United States); Wojciech Haske, Ehsan M. Najafabadi, Talha M. Khan, Hossein Sojoudi, Stephen Barlow, Samuel Graham, Jean-Luc Brédas, Seth R. Marder, Georgia Institute of Technology (United States); Antoine L. Kahn, Princeton Univ. (United States); Bernard Kippelen, Georgia Institute of Technology (United States)

Organic photovoltaic technologies have been the subject of active research and development over the past decades. Due to their ability to be processed at low temperature, over large areas, at potentially low cost, organic solar cells have experienced an accelerated development in recent years and have the potential to spawn a new generation of products with thin and flexible form factors. However, despite a steady progress in performance, many challenges and concerns about stability and cost remain before this emerging technology can unleash its full potential.

In this work, we show that surface modifiers based on polymers containing simple aliphatic amine groups substantially and universally reduce the work function of conductors including metals, transparent conductive metal oxides, conducting polymers, and graphene. The reduction arises from physisorption of the neutral polymer, which turns the modified conductors into electron-selective electrodes. These polymer surface modifiers are processed in air from solution, providing an appealing alternative to chemically-reactive low?work function metals. With this modification, various types of efficient single- and multi-junction solar cells, including all-plastic solar cells, have been demonstrated. The multi-junction solar cells with the new recombination layer show fill factor over 70% and power conversion efficiency over 8%.

The polymer surface modification turns out to be an efficient method to produce air-stable low?work function electrodes for organic solar cells. This approach should enable the mass production of low?work function electrodes from processes that are compatible with the large-area roll-to-roll manufacturing techniques required for the commercialization of low-cost organic and printed electronic devices.

8830-10, Session 2

Flexible and transparent graphene electrodes fabricated by residue-free doping transfer

Byoung Hoon Lee, Jong-Hoon Lee, Yung Ho Kahng, Nara Kim, Kwanghee Lee, Gwangju Institute of Science and Technology (Korea, Republic of)

The breakthrough discovery of fabricating graphene flakes via mechanical exfoliation in 2004 began the experimental discovery of the outstanding physical and chemical properties of graphene. Consequently, graphene was envisioned as a highly functioning component for various applications, including flexible and transparent electrodes. However, three key issues—high-quality synthesis, residue-free transfer, and stable doping—need to be addressed for the practical application of graphene. Although the scaled-up synthesis of large-area graphene via chemical vapor deposition set a milestone in the development of graphene for applications, the latter two issues have not yet been satisfied. Here, we report a new graphene transfer process that solves these bottlenecks by using poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) as a new supporting layer. Because PEDOT:PSS is a well-known conducting polymer widely used as a hole transport layer in many organic optoelectronic devices, the graphene/PEDOT:PSS bilayer electrodes can be directly used for many applications without removing the supporting layer. Therefore, our new transfer method eradicates the residue contamination problem of conventional transfer methods. Furthermore, we confirm that the graphene was doped by the PEDOT:PSS with high stability during the new transfer process. Consequently, the new graphene/PEDOT:PSS electrodes demonstrate superior performance to both graphene electrodes fabricated via the conventional transfer method and indium tin oxide electrodes. Polymer solar cells with 5.5% (solid) and 4.8% (flexible) efficiencies were constructed using our new graphene electrodes. The combination of the remarkable, recently developed synthesis techniques with our transfer method will allow graphene to become a dominant electrode material in organic electronics.

8830-11, Session 3

Progress in making organic solar cells highly efficient and stable *(Invited Paper)*

Michael D. McGehee, Stanford Univ. (United States)

Some of the key questions regarding polymer solar cells are why certain bulkheterojunctions have internal quantum efficiencies higher than 90%, what is the optimal morphology and why fullerenes are by far the best electronic acceptors. We will show that in several highly efficient solar cells there is a three-phase morphology in which there are pure regions of polymer and fullerenes along with a mixed region. We will show that there are energetic offsets that push electrons and holes out of the mixed region and into the pure region. One can control the size and composition of the phases by adjusting factors such as the regioregularity and molecular weight of the polymer, the polymers sidechains, the donor:acceptor ratio, the choice of fullerenes, the use of processing additives and annealing conditions. We will show how one can decide what to adjust to get the ideal morphology and thereby obtain high energy conversion efficiency in solar cells. We will also discuss the mechanisms of degradation and polymer solar cells and how the lifetime can be extended.

8830-12, Session 3

The role of material interfaces on the efficiency and lifetime of organic solar cells *(Invited Paper)*

Elizabeth von Hauff, Albert-Ludwigs-Univ. Freiburg (Germany) and Fraunhofer-Institut für Solare Energiesysteme (Germany)

In this talk the role of contact interfaces on the efficiency and lifetime of polymer:fullerene bulk heterojunction (BHJ) solar cells is discussed. BHJ cells are most commonly fabricated on a transparent substrate coated with an ITO:PEDOT:PSS anode, and a low work function cathode is applied on the top of the stack. From the point of view of stability and performance this structure has significant drawbacks. Suboptimal vertical phase segregation during blend drying leads to an accumulation of polymer at the anode and fullerene at the cathode which reduces the collection of charge from the active layer and overall solar cell performance [1]. Additionally, the emergence of trap states at contact interfaces [2] can be traced to intrinsic instabilities of the anode materials. To locate loss sites in operational BHJJ devices we apply an equivalent circuit model of the BHJ cell based on extensive impedance spectroscopy analysis [3]. Finally, a stable ITO-free inverted solar cell architecture is demonstrated. Solar cell efficiencies are comparable to those obtained in the standard architecture [4].

8830-13, Session 3

Stability investigations of inverted organic solar cells with a sol-gel processed ZnSrO or ZnBaO electron extraction layer

Olympia Pachoumi, Cheng Li, Yana Vaynzof, Kulbinder K. Banger, Henning Sirringhaus, Univ. of Cambridge (United Kingdom)

Stability of organic photovoltaic devices is a limiting factor for their commercialization and still remains a major challenge whilst power conversion efficiencies are now reaching the minimum requirements. The inverted organic solar cell architecture shows promising potential for improving significantly the cell's working lifetime however, often when solution processed ZnO is used as electron extraction layer (EEL), a light soaking step is required before the device reaches a non-permanent maximum performance. Here we show that by doping ZnO with Sr or Ba using sol-gel processing the light-soaking step is circumvented. In a model poly [3-hexylthiophene] (P3HT): [6, 6]-Phenyl C60 butyl acid methyl ester (PCBM) system we obtain EQE ~ 55% before UV exposure for ZnSrO or ZnBaO EELs as compared to 10% for undoped ZnO EEL. We have investigated the origin of this improvement by comparing the response to UV light of doped and undoped ZnO. Characterization includes electrical conductivity and x-ray photoemission spectroscopy studies on thin films, current-voltage experiments and electroabsorption (EA) spectroscopy to probe the built-in field in the devices. We will discuss how the results obtained and in particular the higher effective built-in field in doped ZnO devices (~1.5V) compared to a ZnO device (<0.5V) can help interpret the mechanism behind the device performance improvement with Sr and Ba doping of ZnO. Having designed a more passivated EEL we use high resolution optical spectroscopy [1] to further study the role of oxygen and water in degradation of a highly performing ZnSrO/PTB7:PC70BM system. [1] R. Di Pietro, H. Sirringhaus, Adv Mater 2012, 24, 3367.

8830-14, Session 3

The impact of organic impurities on OPV lifetime

William R. Mateker, Stanford Univ. (United States); Jessica Douglas, Univ. of California, Berkeley (United States); Clement Cabanetos, King Abdullah Univ. of Science and Technology (Saudi Arabia); Isaac T. Sachs-Quintana, Jonathan A. Bartelt, Eric T. Hoke, Stanford Univ. (United States); Abdulrahman El Labban, Pierre M. Beaujuge, Jean M. J. Fréchet, King Abdullah Univ. of Science and Technology (Saudi Arabia); Michael D. McGehee, Stanford Univ. (United States)

As the efficiency of organic photovoltaics continually improves, and is now as high as 12.0%, more research is directed at understanding and improving device lifetime. To what extent impurities affect device lifetime is currently under investigation. Metallic impurities are suspected to play a role in the lifetime of many organic semiconductor electronics. However, organic impurities can also hinder solar cell lifetimes. In this work, we study the lifetimes of solar cells made from batches of high and low molecular weight PBDTTPD. We find that high molecular weight PBDTTPD produces solar cells with a power conversion efficiency greater than 8.0%, but solar cells suffer a distinct degradation feature characterized by an S-shape in the current-voltage curve that increases in severity with time. An extraction barrier that forms at the cathode of the devices causes this degradation feature. Solar cells made from low molecular weight PBDTTPD, though less efficient, do not develop the characteristic S-shape degradation feature. However, this degradation feature is reproduced in these more stable solar cells by introducing a low molecular weight organic impurity. Finally, high molecular weight PBDTTPD, purified by column chromatography to reduce low molecular weight content, as compared to unpurified batches is shown to produce solar cells with comparable efficiencies and long lifetimes.

8830-15, Session 4

Towards high performance inverted polymer solar cells *(Invited Paper)*

Xiong Gong, The Univ. of Akron (United States)

Bulk heterojunction polymer solar cells that can be fabricated by solution processing techniques are under intense investigation in both academic institutions and industrial companies because of their potential to enable mass production of flexible and cost-effective alternative to silicon-based electronics. Despite the envisioned advantages and recent technology advances, so far the performance of polymer solar cells is still inferior to inorganic counterparts in terms of the efficiency and stability. There are many factors limiting the performance of polymer solar cells. Among them, the optical and electronic properties of materials in the active layer, device architecture and elimination of PEDOT:PSS are the most determining factors in the overall performance. In this presentation, I will present how we approach high performance of polymer solar cells. For example, by elimination of PEDOT:PSS, development of novel materials, fabrication of inverted polymer solar cells, we were able to observe over 50 % enhanced efficiency.

8830-16, Session 4

Optimizing and enhancing the efficiency of organic tandem solar cells by spatial photocurrent mapping

Andreas Pütz, Konstantin Glaser, Christian Sprau, Uli Lemmer, Alexander Colsmann, Karlsruher Institut für Technologie (Germany)

Record efficiencies of organic tandem solar cells recently approached 12%. The key to further efficiency improvements will be a smart choice of complementary absorbing materials for both subcells within a properly designed device architecture. As the device absorption is ruled by thin film interferences and as the matching of currents in both subcells is of major importance in order to achieve best device performance, the thicknesses of each layer in the device have to be optimized carefully. However, experimentally optimizing numerous functional layers in a tandem device on a sample-by-sample basis is a very time and material consuming task.

In this work we present a facile route to an efficient experimental screening of new materials and layer thickness optimization in solution processable tandem polymer photovoltaic devices. Therefore, we developed a method of fabricating tandem solar cells with a graded active layer thickness. Spatially resolved mapping of the solar cell short circuit current density for different light absorbing polymers under white light allows for a quick conclusion about the optimum active layer thickness within the device. When plotting the short circuit current density versus the local active layer thickness, the influence of the thin film interference pattern within the device becomes apparent. The measured short circuit current densities are in very good accordance with optoelectronic device simulations for all layer thicknesses.

In tandem solar cells, this technique is an efficient tool for matching both subcell currents with only little experimental effort and hence building tandem solar cells with high power conversion efficiencies.

8830-17, Session 4

Four-terminal organic solar cell modules with increased annual energy yield *(Invited Paper)*

Robert Gehlhaar, David Cheyns, Luuk Van Willigenburg, Afshin Hadipour, IMEC (Belgium); Roshanak Radbeh, Solvay S.A. (Belgium); Tom Aernouts, IMEC (Belgium)

With the rapidly improving efficiencies of organic solar cells and current records of 12% new device designs are needed to transfer these achievements from small area lab demonstrators to large area modules. Nowadays, the record organic solar cells consist of tandem structures where two complementary absorbing solar cells are combined in order to efficiently harvest light from different parts of the solar spectrum. The vertical assembly of two devices demands sophisticated optical and electrical alignments . Optically, the layer stack has to be optimized to maximize the absorption of a certain spectral range in the corresponding subdevice. The serial electrical connection requires a current matching of the two subcells. An optimum achieved mainly by a variation of the layer thicknesses within the stack is limited to certain light spectrum and angle of incidence.

We present a four-terminal organic solar cell module that shows a low dependence on the incident light conditions. A semi-transparent and an opaque submodule with aperture areas of 16cm2 each are mechanically combined to a device with the same aperture area that does not require additional encapsulation. The fabrication process includes the development of a mechanical scribing process for the efficient module patterning leading to a geometrical fill factor of 94%. We are going to present semitransparent submodules with 5.0% efficiency which in combination with an opaque submodule give devices with 6.5% efficiency.

The presentation closes with a view on the total annual energy yield of the presented design in comparison to conventional structures.

8830-18, Session 4

Efficient tandem polymer solar cells with a PEDOT:PSS/nonconjugated polyelectrolyte intermediate layer

Jinho Lee, Hongkyu Kang, Jeamin Kong, Kwanghee Lee, Gwangju Institute of Science and Technology (Korea, Republic of)

We report efficient tandem polymer solar cells (TPSCs) using a PEDOT:PSS/nonconjugated polyelectrolytes (NPEs) as an intermediate layer (IML). By applying the NPEs to the electrode surfaces of the TPSC structure, the work functions (WFs) of indium tin oxide (ITO) cathode for front subcell and a poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) cathode for back subcell are significantly reduced to 3.95 eV and 3.88 eV, respectively. Kelvin probe (KP) and x-ray photoelectron spectroscopy (XPS) studies indicate that protonated amines of the NPEs are responsible for the WF changes of the electrodes. Furthermore, we confirm that by increasing the degree of protonation of the amine group in NPEs, the electrode WFs can be dramatically reduced. Because the modified WFs of the electrodes form ohmic contacts with the lowest unoccupied molecular orbital (LUMO) level of fullerene and induce strong electric fields inside each subcells, we successfully demonstrate the highly efficient TPSCs with power conversion efficiency of 7.8 %.

8830-19, Session 4

Fullerene based organic Schottky-junction devices for large open circuit voltage organic solar cells

Jinsong Huang, Bin Yang, Univ. of Nebraska-Lincoln (United States)

Generally it is believed that Schottky-junction structure cannot be used in organic photovoltaic devices (OPVs) for a reasonably high efficiency. In this manuscript we reported the fullerenes based Schottky-junction devices which output a larger open circuit voltage (Voc) (0.85-0.95 V) than most of bulk heterojunction (BHJ) OPVs, i.e. 0.60 V for P3HT:PCBM devices. A small concentration of P3HT doping (5 wt%) won't change the Voc while increases the short circuit current (Jsc) to be comparable to that of P3HT:PCBM BHJ devices. This Schottky-junction device has three major advantages: First, since its Voc is governed by the Fermi level of the fullerene and the work function of anode, a larger Voc of more than 1 V can be potentially achieved with easily tuning the work function of the anode; Second, the resulted high efficiency of 5% at low light intensity, much larger than that of P3HT:PCBM BHJ devices, makes it very attractive for the application of indoor light energy harvesting; Third, this device is much more stable than BHJ OPVs due to less donor polymer aggregation. We believe this work will raise the broad interest in OPV society to explore the potential of Schottky-junction structure for high efficiency and long lifetime OPVs.

8830-20, Session 4

New insights on the role of the donor material in C60-based Schottky-junction small molecule organic solar cells

Sibi Sutty, Graeme M. Williams, Hany Aziz, Univ. of Waterloo (Canada)

C60 based Schottky-junction solar cells have shown promising performance with high power conversion efficiencies. Zhang et al. reported PCEs as high as 5.23% with a Voc of 0.91V for a cell with the structure: ITO/MoO3/C70:TAPC (5%)/BPhen/Al. However, there are several unanswered questions about the role of the Schottky-junction and the donor material in enabling high photovoltaic performance. In literature, the Voc of these cells was observed to be independent of the donor material suggesting that it is determined by the band-bending present at the ITO/MoO3/C60 interface. The enhanced Jsc seen with the addition of donor material has been attributed to the dissociation of Frenkel excitons formed in C60. The exact mechanism of hole extraction is however unclear. Furthermore, only a limited range of materials were tested. In order to further understand the factors governing the performance of these OSCs, we carried out a systematic comparative study utilizing a range of materials of various HOMO and LUMO levels as donors. The materials are selected to produce different HOMO-LUMO offsets with C60. The effect on Voc and charge extraction were studied. Contrary to reports in literature, we found that the Voc is affected by the HOMO-LUMO difference between the donor material and C60. We also found that the enhanced Jsc can be achieved by means of altering device architecture. In light of these findings, a revised explanation for the operation of Schottky-junction cells will be presented.

8830-21, Session 5

Light management approaches in nanostructured organic semiconductor thin films *(Invited Paper)*

Deirdre M. O'Carroll, Gary Cheung, Christopher Petoukhoff, Rutgers, The State Univ. of New Jersey (United States)

In this presentation, we will discuss two approaches for light management in organic thin film photovoltaic devices. We will show that binary and ternary blend thin films of organic conjugated polymer and oligomer materials can double the fraction of solar energy absorbed compared to single component thin films. Additionally, photoluminescence measurements show that excitonic energy transfer efficiency between the different materials within the thin film blends can approach 100 % by optimizing the relative fraction of each material in the blend. We propose that such ternary blends can offer an alternative to more complex tandem organic photovoltaic device architectures.

Additionally, light management though the application of plasmonic electrodes will be presented as a route to further improve the effective absorption depth and generation rate in inverted bulk-herterojunction organic photovoltaic devices (BHJ-OPVs). We will discuss our recent theoretical and experimental results on the performance and fabrication of nanostructured plasmonic electrodes. We have found that the interaction of light with plasmonic nanostructured electrodes can result in three distinct phenomena that can affect the device performance: 1) localized, resonant electromagnetic field enhancement; 2) light scattering; and 3) propagating electromagnetic surface waves. The first effect provides 'hot spots' within about 50 nm of the nanostructured electrodes, which can increase the generation rate of the charge carriers in semiconductors placed nearby. The second and third effects increase the optical path length in the active layer, increasing total light absorption. All of these effects combined can potentially increase the overall efficiency of BHJ-OPVs if designed properly.

8830-22, Session 5

Morphology and growth of organometal halide perovskite films for highly efficient hybrid solar cells

Giles E. Eperon, Victor M. Burlakov, Pablo Docampo, James M. Ball, Michael M. Lee, Henry J. Snaith, Univ. of Oxford (United Kingdom)

Solution-processable semiconducting perovksite materials have recently shown significant promise as absorbers in sensitized solar cells, and it has been found that they can also act as electron or hole transporters [1,2,3]. A key challenge in this new field is optimising solar cell architecture to enable maximum efficiencies; in the specific case of methylammonium lead halide perovskite a high-temperature processed mesostructured layer is used for the best performing devices [4]. Since the perovskite absorber is capable of absorbing light, generating free charge and transporting electrons, we no longer require a thermally sintered mesoporous oxide to enable efficient charge collection; we have been able to eliminate all sintering steps in the manufacture of these solar cells. However, the current 11% efficient devices are still composed of inhomogeneous layers. Challenges in fabrication of continuous perovskite films arise from the development of pinholes within the film upon annealing. These occur due to the interplay between perovskite surface energies with the substrate and air, the effects of rapid crystallisation upon drying, and stoichiometry-driven mass loss.

Here we report on a detailed study on the growth and morphology of the methylammonium lead halide perovskite. We have developed and experimentally verified a mathematical model describing dynamic pinhole growth in such films. Using the insights gained we have optimised the formation of continuous perovskite films, and from this we have fabricated hybrid methylammonium lead halide perovskite devices demonstrating efficiencies in excess of 10%, with the active layer fully processed below 150°C.

8830-23, Session 5

Highly transparent polymer solar cells achieving 5% efficiency

Chun-Chao Chen, Yang Yang, Letian Dou, Univ. of California, Los Angeles (United States)

In this work, we demonstrated a high-performance solution-processed transparent polymer solar cell. So far, no significant progress has been made on the transparent PV device due to the lack of transparent PV materials and top electrodes. Upon the utilization of high performance low bandgap polymer, the photoactive layer absorbs more near-infrared light while being less sensitive to visible light. The transparent electrode is a fully solution-processed conducting silver nanowire-based composite film with indium tin oxide nanoparticles. With this combination, we have achieved 5% power-conversion efficiency for the fully solution-processed transparent solar cells on indium-tin-oxide-coated glass substrates.

8830-24, Session 5

Patternable conjugated polymers for organic solar cells

Peter Strohriegl, Philipp Knauer, Christina Saller, Esther Scheler, Univ. Bayreuth (Germany)

Semiconducting polymers have gained large interest during the last two decades. In view of applications in OLEDs and Organic Solar Cells (OSCs) patterning of conjugated polymers to small feature sizes is of particular interest.

A number of patterning techniques are known, which can be divided into top-down and bottom-up approaches. A typical bottom-up approach uses the self-assembly of materials (e.g. block copolymers). With this strategy very small feature sizes are accessible, but there are severe limitations in the shape of possible structures, which are predetermined by the interplay of forces between different materials in the self-assembly process.

The formation of patterns with arbitrary shape is a big advantage of top-down methods like printing and lithography. A high resolution of much less than 100 nm can be obtained using both photolithography and special printing techniques like microcontact printing.

We present a lithographic approach for the formation of polymer multilayers and microstructures from photocrosslinkable polyfluorenes and polyfluorene copolymers. For this purpose we synthesised fluorene based polymers with photopolymerisable acrylate groups. Subsequent photopolymerisation leads to densely crosslinked and insoluble polymer films. Using a µm-sized photoresist test mask patterns with a minimum size of 700 nm are formed [1-3]. Meanwhile we have extended the synthesis to photocrosslinkable low bandgap polymers like PCDTBT with crosslinkable oxetane units. First work on how to use patterned organic semiconductors in organic solar cells will be presented.

8830-25, Session 5

Flow techniques for the synthesis of semiconducting polymers

James H. Bannock, Siva H. Krishnadasan, Adrian M. Nightingale, Martin J. Heeney, John C. de Mello, Imperial College London (United Kingdom)

There is an urgent need for improved methods of producing sizeable volumes of high-quality semiconducting polymers for large area plastic electronics. We have recently developed a stable droplet reactor for synthesising poly(3-hexylthiophene) (P3HT). Using this approach it is possible to tune molecular weight and regioregularity with superior control to conventional batch methods. Here we present an overview of techniques for polymer synthesis in flow, showing how the exploitation of reactions on the micro-scale leads to significantly enhanced rates of reaction, synthetic control and reproducibility and narrowing of polydispersity.

Our method sees the injection of monomeric species and catalysts into a flowing stream of inert fluid fluoropolymer in a narrow PTFE capillary, creating sub-microlitre sized reaction droplets. The droplet method overcomes a common problem with continuous flow methods where reactors are liable to clogging. The inert fluoropolymer has the effect of preferentially wetting the reactor surface preventing the reaction mix from interacting with the surface, eliminating reactor ageing. Initial tests have shown that it is possible to produce material at rates approaching 100 g/day with significant potential for further scaling.

8830-26, Session 6

Diketopyrrolopyrrole based molecular semiconductors: versatile materials for organic solar cells and ambipolar field-effect transistors *(Invited Paper)*

Satish Patil, Indian Institute of Science (India)

Since the inception of bulk hetero junction (BHJ) concept there has been tremendous growth in organic photovoltaics (OPV) and produced device with efficiencies up to 9.8%. Major criteria for this remarkable performance originate from adaption of donor-acceptor (D-A) or donor-acceptor-donor (D-A-D) concept in design of low band gap polymers. With a myriad of donor type of materials synthesized the major focus of various research groups lies in using diketopyrrolopyrrole (DPP) as an acceptor and combining with electron rich units like phenyl, thiophene and other aromatic heterocycles to generate novel D-A and D-A-D type copolymers with high efficiency. Focus of talk is on synthesis of DPP-DPP based low band gap D-A-D type copolymers. This novel idea of self-coupling thiophene DPP with itself, each unit having different alkyl chain, has yielded copolymers with high molecular weight, low PDI and better overlap with solar spectrum. Top gate OFET by using these polymers exhibited highest n-type mobility (3 cm2V–1s–1) reported till date.

8830-27, Session 6

Complementary absorbing star-shaped small molecules for the preparation of ternary cascade energy structures in organic photovoltaic cells

Hyojung Cha, Pohang Univ. of Science and Technology (Korea, Republic of); Dae Sung Chung, Dong-A Univ. (Korea, Republic of); Suk Young Bae, Korea Univ. (Korea, Republic of); Min-Jung Lee, Yun-Hi Kim, Gyeongsang National Univ. (Korea, Republic of); Dong Hoon Choi, Korea Univ. (Korea, Republic of); Chan Eon Park, Pohang Univ. of Science and Technology (Korea, Republic of)

Two anthracene-based star-shaped conjugated small molecules, 5',5''-(9,10-bis((4-hexylphenyl)ethynyl)anthracene-2,6-diyl)bis(5-hexyl-2,2'-bithiophene), HBantHBT, and 5',5''-(9,10-bis(phenylethynyl)anthracene-2,6-diyl)bis(5-hexyl-2,2'-bithiophene), BantHBT, were used as electron-cascade donor materials by incorporating them into organic photovoltaic cells prepared using a poly((5,5-E-alpha-((2-thienyl)methylene)-2-thiopheneacetonitrile)-alt-2,6-[(1,5-didecyloxy)naphthalene])) (PBTADN):[6,6]-phenyl-C71-butyric acid methyl ester (PC71BM) blend. The small molecules penetrated the PBTADN:PC71BM blend layer to yield complementary absorption spectra through appropriate energy level alignment and optimal domain sizes for charge carrier transfer. A high short-circuit current (JSC) and fill factor (FF) were obtained using solar cells prepared with the ternary blend. The highest photovoltaic performance of the PBTADN:BantHBT:PC71BM blend solar cells was characterized by a JSC of 11.0 mAcm–2, an open circuit voltage (VOC) of 0.91 V, a FF of 56.4%, and a power conversion efficiency (PCE) of 5.6% under AM1.5G illumination (with a high intensity of 100 mW–2). The effects of the small molecules on the ternary blend were investigated by comparison with the traditional poly(3-hexylthiophene) (P3HT):[6,6]-phenyl-C61-butyric acid methyl ester (PC61BM) system.

8830-28, Session 6

Solution processable small molecules for organic photovoltaics

Scott E. Watkins, Kevin N. Winzenberg, Gavin E. Collis, Peter Kemppinen, Thokchom B. Singh, Fiona H. Scholes, Commonwealth Scientific and Industrial Research Organisation (Australia)

This paper will discuss the issue of molecular association with regards to small molecule donor material and its effect on the open circuit voltage in organic solar cells based on these materials. The paper will also introduce a new class of small molecule semiconductors based on solubilised indene derivatives. Their performance as N-type materials in solution-processed organic solar cells will be discussed. The development of alternatives to commonly used fullerenes enables the exploration of a wider parameter space in which to improve the performance of devices. A family of derivatives based on the parent compound, F8IDT, have been prepared through simple synthetic routes upto 20g in scale. Solution processed BHJ OPVs have been prepared using F8IDT as the acceptor and P3HT as the donor. Power conversion efficiencies in excess of 2% will be reported. We will also show correlations between the calculated and measured LUMO energy levels and the device open circuit voltages that highlight the validity of our approach to the design of new n-type materials. Finally, physical and electronic characterisation data will be presented to discuss the influence of molecular structure on device performance.

8830-29, Session 6

Improving the performance of P3HT/PCBM solar cells with squaraine dye

Jing-Shun Huang, Tenghooi Goh, Xiaokai Li, Yale Univ. (United States); Matthew Y. Sfeir, Brookhaven National Lab. (United States); Elizabeth A. Bielinski, Stephanie Tomasulo, Minjoo L. Lee, Nilay Hazari, Andre D. Taylor, Yale Univ. (United States)

Expanding the spectral absorption breadth and efficiently harvesting excitons are crucial towards creating highly efficient polymer solar cells. A common strategy is to adopt a tandem structure consisting of multiple subcells. However, in polymer tandem cells it is technically challenging to design and optimize each subcell and the interconnecting layers between the subcells. Here we describe an alternative strategy to realize broad-band light harvesting in poly(3-hexylthiophene) (P3HT)-based solar cells. We introduce the use of squaraine dye molecules that play a dual role towards improving P3HT-based solar cells. The first benefit is an increase in the spectral absorption in the near infrared region. The second advantage is the collection of excitons close to the interfacial heterojunctions via Förster resonance energy transfer (FRET). Unlike traditional multi-blend systems, where each donor works independently in separate spectral responses, FRET-based systems enable the effective use of multiple donors with significant improvements in light absorption and conversion. Our ultrafast transient absorption experiments show that the excitation energy from P3HT can be transferred rapidly (within a few picoseconds) and efficiently (up to 96%) to the squaraine via FRET. Thus, the external quantum efficiency increases in both the visible and the near-infrared regions. In addition, nano-morphology of the photoactive layer with an interpenetrating network is well developed by SQ. As a result, the overall power conversion efficiency is dramatically improved from 3.27% to 4.51%. This architecture opens up a new paradigm towards transformative improvements of polymer solar cells.

8830-30, Session 6

Probing charge carrier dynamics in organic solar cells based on merocyanines

Steven Graf, Martin R. Lenze, Julian Krumrain, Dirk Hertel, Klaus Meerholz, Univ. zu Köln (Germany)

Highly efficient organic bulk heterojunction (BHJ) solar cells can be produced by various methods such as coating from solution (SOL) or depositing under high vacuum conditions (VAC).

We investigate merocyanines (MC), a class of low-molecular-weight colorants, as donor material in organic BHJ solar cells. These small molecules are processable via both deposition techniques, showing remarkable PCEs beyond 4% for SOL-processed and 6% for VAC-processed devices.

Since MC solar cells suffer from rather poor fill factors of well below 50%, it is mandatory to obtain a better insight into physical processes such as charge carrier generation, transport and recombination. We use steady state and time resolved photoluminescence (PL) spectroscopy to examine emissive states in pure and blended merocyanine thin films. While we find emission of both thermally populated states as well as states with strong CT character in pure films, distinct quenching of an emissive CT state between the MC donor and the PCBM acceptor can be spotted in blended films under presence of an electric field. By varying the donor/acceptor composition in devices, the influence of morphology on the solar cell parameters is illustrated and further studied by temperature dependent current-voltage and external quantum efficiency (EQE) measurements. The recombination and transport dynamics of free charge carriers are probed by the photo-CELIV technique. Despite the high dipole moments of MC molecules, optimized devices show decent charge-carrier mobilities and densities at room temperature. However, bimolecular recombination of free charge carriers at weak internal fields appear to be the highest loss channel in MC solar cells.

8830-48, Session PWed

Investigate the role of the active layers structures and morphology in the performance of the organic solar cell devices

Ronak Rahimi, West Virginia Univ. (United States); Alex Roberts, V Narang, D. Korakakis, West Virginia University (United States)

Several CuPc/PTCDI-C8 films with different structures (co-deposited, layered and bilayer) were prepared and their structural properties were studied using X-ray diffraction. In order to study the effects of the active layers' structures on the performance of the device, organic solar cells based on these films were fabricated and their electrical characteristics have been explored. Absorbed prominent diffraction peaks for CuPc/PTCDI-C8 bilayer films indicate the formation of higher degree of crystallinity for this structure compared to the films with layered or co-deposited structures. This crystallinity results in higher device performance due to reduced recombination losses and microscopic shorts within the devices.

8830-50, Session PWed

Loss mechanisms in hybrid plasmonic bulk heterojunction organic solar cells

Bo Wu, Tze Chien Sum, Xiangyang Wu, Nripan Mathews, Hong Jin Fan, Edwin Kok Lee Yeow, Cao Guan, Kong Fai Tai, Nanyang Technological Univ. (Singapore)

Controversy has been found over the effects of organic ligand encapsulated plasmonic nanoparticles blended in bulk heterojunction organic solar cells where both enhancement and degradation in performance have been reported. Herein, using a suite of transient optical spectroscopy and electrical characterization techniques, we have revealed the evidence of traps being responsible for the performance degradation in organic solar cells fabricated with oleylamine-capped silver nanoparticles (AgNPs) blended in poly (3-hexylthiophene):[6,6]-phenyl-C 61-butyric acid methyl ester (P3HT:PCBM) active layer. Traps can introduce two different loss mechanisms: (a) interfacial traps at the interface regions of P3HT:PCBM domains that are dominated by the Shockley-Read-Hall recombination; and (b) intra-domain traps located within a phase separated domain increase the energetic disorder of the density of states, thereby impeding the charge hopping. The new insight would resolve the existing controversy and provide guidelines for the design of hybrid plasmonic organic solar cells.

8830-52, Session PWed

Transient spectroscopies in studying loss mechanisms in silver nanoparticles-blended bulk heterojunction organic solar cells

Bo Wu, Xiangyang Wu, Cao Guan, Kong Fai Tai, Edwin Kok Lee Yeow, Hong Jin Fan, Nripan Mathews, Tze Chien Sum, Nanyang Technological Univ. (Singapore)

The effects of organic ligand encapsulated plasmonic nanoparticles blended in bulk heterojunction organic solar cells have been controversial. Both enhancement and degradation in performance of organic solar cells have been reported. Herein, a comprehensive suite of transient optical spectroscopy and electrical characterization techniques were used to uncover that traps are responsible for the performance degradation in organic solar cells fabricated with oleylamine-capped silver nanoparticles (AgNPs) blended in poly (3-hexylthiophene):[6,6]-phenyl-C 61-butyric acid methyl ester (P3HT:PCBM) active layer. The trap-assisted recombination rate was found to be increased by three times upon incorporation of AgNPs. Besides, charge transport will also degrade due to the increased disorder in the density of states (DOS). These new insights would resolve the existing controversy and provide guidelines for the design of hybrid plasmonic organic solar cells.

8830-53, Session PWed

Application of DSSC dyes as efficient donor materials for small-molecule-based organic photovoltaics

Xiao-Feng Wang, Yamagata Univ. (Japan)

A donor-acceptor (D-A) type dye-sensitized solar cell (DSSC) dyes, were used as an electron donor in organic solar cells (OSCs). For bulk-heterojunction (BHJ) type OSCs with PCBM as electron acceptor, the power conversion efficiency (PCE) is sensitive to the amount of donor in the donor/PCBM blend film. In order to improve the PCE of DSSC dye based OSCs, bilayer- and bulk-heterojunction configuration with C70 as electron acceptor has been employed. By optimization of the thickness of active layer and variation of the electron- and hole-transport layers, the highest PCE of up to 4.5% with a Jsc of 9.1 mA cm-2, a Voc of 0.89 V, and an FF of 0.56 was achieved under AM 1.5G solar illumination (100 mW cm-2)

8830-54, Session PWed

Effects of pressure on contact between layers in organic solar cells

Benjamin Agyei-Tuffour, African Univ. of Science and Technology (Nigeria)

This paper investigates the effects of pressure on the contacts between layers organic solar cells with poly (3-hexylthiophene):phenyl-C61-butyric acid methyl ester (P3HT:PCBM) as active layer. The contacts between the layers are modeled using analytical concepts and finite element models. The potential effects of surface roughness and dust particles are modeled along with the effects of lamination pressure and adhesion energy. The results show that, improved contact and adhesion decreases the void length while increasing the contact length. The contacts associated with the interfaces between the active layer (P3HT: PCBM) and the hole/electron injection layer Poly(3,4-ethylenedioxythiophene): Poly (styrenesulphonate) (PEDOT.PSS) and Molybdenum Trioxide (MoO3) are also compared. The implications of the results are discussed for the design of stamping/lamination processes for the fabrication of the organic solar cells.

8830-55, Session PWed

Surface plasmon resonance of carbon dot-supported silver nanoparticles

Taehyo Kim, Ulsan National Institute of Science and Technology (Korea, Republic of)

The coupling of surface plasmons and excitons in organic materials can improve the performance of organic optoelectronic devices.1,2 Here, we fabricate solution-processed polymer light-emitting diodes (PLEDs) and polymer solar cells (PSCs) using carbon dot-supported silver nanoparticles (CD-Ag NPs). The surface plasmon resonance effect of CD-Ag NPs allows significant radiative emission and additional light absorption and achieves a remarkably enhanced current efficiency (CE) of 27.16 cd A-1 and a luminous efficiency (LE) of 18.54 lm W-1 in PLEDs as well as a power conversion efficiency (PCE) of 8.31% and an internal quantum efficiency (IQE) of 99% in PSCs compared with devices without CD-Ag NPs (CE = 11.65 cd A-1, LE = 6.33 lm W-1 in PLEDs and PCE = 7.53%, IQE = 91% in PSCs). To the best of our knowledge, these device efficiencies in PLEDs and PSCs with CD-Ag NPs are record-high values in plasmonic polymer optoelectronic devices with metal nanoparticles.

8830-57, Session PWed

Effects of ionic liquid molecules in hybrid PbS quantum dot - organic solar cells

Hak-Beom Kim, Ulsan National Institute of Science and Technology (Korea, Republic of)

We investigated the effect of ionic liquid molecules (ILMs) in quantum dot-organic hybrid solar cells. The insertion of an ILMs layer between PbS and PCBM can shift the band edge of PCBM closer to the vacuum level of PbS due to spontaneous dipole polarization. Owing to this new architecture, improvements in device performance were achieved, including an increase in VOC from 0.41 V to 0.49 V, FF from 0.48 to 0.59 and PCE from 1.62% to 2.21% compared to reference devices under AM 1.5G illumination at 100 mW cm-2. We observed that treatment of the PbS layer with ILMs causes a significant increase in work function from 3.58 eV to 3.93 eV. Furthermore, the ILMs layer minimizes the contact resistance between PbS and PCBM due to the improved compatibility between the two layers, confirmed as a decrease in charge transfer resistance as measured by electrical impedance spectroscopy.

8830-58, Session PWed

An optimization algorithm for designing robust and simple antireflection films for organic photovoltaic cells

Shigeru Kubota, Kensaku Kanomata, Katsuaki Momiyama, Takahiko Suzuki, Fumihiko Hirose, Yamagata Univ. (Japan)

We propose a method to design multilayer antireflection (AR) structure, which has robustness against variations in layer thicknesses, for organic solar cells. When a set of available materials are given, the proposed method searches for the material and thickness of each AR layer to maximize the short-circuit current density (Jsc). The algorithm is composed of the following two steps. The first step is to perform global search of the AR structure through the optical analysis using the characteristic matrix method. Here, we use a hybrid optimization scheme that combines the quasi-newton method with many random initial points, for searching the solutions of layer thicknesses, and exhaustive search, for searching those of material combination. This algorithm allows for obtaining a set of solutions, including optimal and quasi-optimal solutions, at the same time, so that we might clearly make comparison between them. In the second step, the effects of deviations in the thicknesses of the AR layers are examined for the (quasi-) optimal solutions obtained by the previous step. The expectation of the decrease in the AR performance is estimated by calculating the changes in Jsc when the thicknesses of all AR layers are varied independently. We showed that some of quasi-optimal solutions may have simpler layer configuration and can be more robust against the deviations in film thicknesses, than the optimal solution. This method indicates the importance of actively searching valuable, non-optimal solutions for practical design of AR films.

8830-60, Session PWed

Evaluation of exciton diffusion in triphenylamine-cored derivatives

Karolis Kazlauskas, Steponas Rai?ys, Vilnius Univ. (Lithuania); Maryte Da?keviciene, Tadas Malinauskas, Vytautas Getautis, Kaunas Univ. of Technology (Lithuania); Saulius Jur??nas, Vilnius Univ. (Lithuania)

Understanding and control of the energy migration is critical for enhancing efficiency of organic electronic devices like light emitting diodes, solar cells etc. Exciton diffusion length is particularly important for organic solar cells, since it reflects the amount of photogenerated excitons that are able to reach donor-acceptor interface and contribute to the photocurrent, and hence, to the device efficiency.

In this work, exciton diffusion in a series of triphenylamine derivatives exhibiting excellent hole drift mobilities (up to 0.02 cm2/Vs) [1] was investigated. Systematic investigations of the exciton diffusion length (L) vs the number and type of the phenylethenyl sidearms linked to the triphenylamine core were carried out. The determination of L was based on the evaluation of fluorescence quenching efficiency in the triphenylamine films with randomly distributed quenchers. For the evaluation, Monte Carlo simulations of the PL transients in triphenylamine/quencher blends with different quencher concentration were performed [2]. The obtained data revealed that the increasing number of phenylethenyl sidearms generally implies larger exciton diffusion coefficient (up to 5.4•10^-4 cm2/s) and also results in the increased exciton diffusion length from 3 nm to 11 nm, most likely due to the denser sidearm network formed. Estimated exciton diffusion lengths are found to be comparable or higher as those of the narrow bandgap polymers employed in modern bulk heterojunction solar cells.

Highly efficient polymer solar cell modules fabricated by slot-die coating method

Soonil Hong, Hongkyu Kang, Gwangju Insititute of Science and Technology (Korea, Republic of); Jongjin Lee, Gwangju Institute of Science and Technology (Korea, Republic of); Kwanghee Lee, Gwangju Insititute of Science and Technology (Korea, Republic of)

Slot-die coating is one of the promising methods for fabricating

large-area polymer solar cells (PSCs) due to its compatibility with roll-to-roll printing and one-dimensional direct patterning. In this study, we investigated correlations between conformal film morphology of intermixed poly(3-hexylthiophene)(P3HT) and fullerene derivative [6,6]-phenyl-C61-butyric acid methyl ester (PCBM) bulk-heterojunction(BHJ) material and universal control factors in slot-die coating method, such as shim length, substrate temperature, and coating speed. The observed correlation equation is better matched to the meniscus coating parameter equation rather than to the traditional high-viscosity extrusion slot-die coating parameter equation. The slot-die coated PSCs with PCE values of 3.07% were successfully fabricated. In addition, high-throughput (5.0 m/min), slot-die-coated PSCs exhibited a uniform average PCE of 2.58%. Also, highly efficient polymer solar cell modules are fabricated by using slot-die coating method.

8830-62, Session PWed

Role of additional PCBM layer in inverted bulk heterojunction solar cells

Dong Chan Lim, Korea Institute of Materials Science (Korea, Republic of); Kwang-Dae Kim, Young Dok Kim, Sungkyunkwan Univ. (Korea, Republic of); Shinuk Cho, Univ. of Ulsan (Korea, Republic of)

High performance inverted organic bulk heterojunction solar cells were demonstrated using a novel polymer, polythienothiophene-co-benzodithiophenes (PTB7-F20), as a donor and phenyl-C61-butyric acid methyl ester as an acceptor. Wet-chemically prepared ZnO and poly(3,4-ethylenedioxythiophene):poly-(styrenesulfonate) (PEDOT:PSS) were used as buffer layers. Particularly, for ZnO layer, self-organized ripple nanostructure were introduced to enhance more light absorption. In addition, in order to induce more easy extraction of electrons, additional PC61BM layer was inserted between active layer and ZnO buffer layer. Inverted BHJ solar cell with additional PC61BM layer exhibited almost 10% higher power conversion efficiency of 7.4% compared to the solar cell without additional PC61BM layer. Unlike our expectation that transit time would have been improved by additional PC61BM layer, intensity modulated photovoltage spectroscopy (IMVS) and intensity modulated photocurrent spectroscopy (IMPS) results indicated that recombination time was more greatly improved with additional PC61BM layer. Based on these IMPS, IMVS results, we concluded that enhanced PCE was attributed to quenching electron–hole recombination at surface defects of ZnO ripples.

8830-63, Session PWed

Understanding the thickness dependent photocurrent spectra of organic bulk heterojunction solar cells

Buddika K. Abeyweera, Bruce W. Alphenaar, Univ. of Louisville (United States)

Photocurrent spectra are measured for bulk heterojunction organic solar cells having a range of active layer thicknesses. Normalized by the number of incident photons, the photocurrent peak red shifts with respect to the absorption maximum as the sample thickness increases. The shift in photocurrent peak can be understood by modeling the carrier extraction as a function of sample thickness. Carriers generated on the sample surface undergo enhanced recombination compared with those in the bulk. For example, bimolecular recombination predominately affects charge generated near the top contact where the carrier concentration is high; recombination of excitons through contact interface states occurs only for photoexcitation near the surface; and recombination of free electrons is larger for charge generated away from the back electron collecting contact. For thick samples, an increased percentage of light away from the absorption maximum contributes to the photocurrent due to carriers generated in the bulk of the sample. Suffering fewer losses than surface generated carriers, the bulk carriers have a relatively large influence on the photocurrent. Fitting the photocurrent spectra as a function of sample thickness differentiates between photocurrent collected from carriers generated in the bulk of the sample versus those generated at the surface, and provides a measure of the electron collection length and the surface enhanced recombination. The variation in the electron collection length with active layer composition and contacting parameters can then be used as a guide for optimization of the solar cell structure

Increase in solar cell performances of transparent conductive oxide-less cylinder dye-sensitized solar cells: simulation on light harvesting, increase in efficiency, and total electric power generation in a day

S. Noguchi, T. Saito, H. Usagawa, Shyam S. Pandey, Yuhei Ogomi, Kyushu Institute of Technology (Japan); Hiroshi Segawa, The Univ. of Tokyo (Japan); Shuzi Hayase, Kyushu Institute of Technology (Japan) and The Univ. of Tokyo (Japan)

It is expected that cylinder type dye sensitized solar cells have an advantage over flat type dye-sensitized solar cells in terms of encapsulation. We have already reported transparent conductive oxide-less cylinder dye-sensitized solar cells (TCO-less cylinder DSC) fabricated inside a glass tube (6.1 % efficiency). The cell consists of a silicone tube (a supporter of a counter electrode)(A), stainless metal mesh tube covered with thin Ti layer (counter electrode)(B), a gel electrolyte tube(C), a porous titania layer stained with dyes(E) fabricated on a stainless metal mesh tube covered with thin Ti layer(D) acting as electron recombination blocking layer, and a plastic tube cover or glass tube cover(F). At first, the efficiency was only 3.39%. Laser beam induced current (LBIC) curves measured at 633 nm were flat across the diameter direction of the cylinder. However, large decreases of LBIC current were observed when the 405 nm laser was used. The large decreases in LBIC were explained by light harvesting loss caused by I-/I3- species (absorption at around 400 nm) which exist in space between an outside wall and a porous titania layer. In order to remove the space consisting of electrolyte, a thermally shrinkable tube (G) was employed as a cover tube(F). The efficiency increased from 3.38% to 5.08%. In addition, the space was filled with a transparent thin plastic layer, which inhibits electrolyte from presenting between the space. By inserting the transparent plastic layer, IPCE values in the area of 400-500 nm increased drastically. The results were explained by simulation results on light harvesting properties. Solar cell performances of TCO-less cylinder DSC with reflector were evaluated. It was found that constant LBIC current was observed across the curved reflector, suggesting that efficient light harvesting were carried out by the curved reflector. The shape of the reflector by light harvesting simulation would be presented. Total electric power of the TCO-less cylinder DSC in a day was compared to that of TCO-less flat DSC. The former was 1.3 times higher than the latter, demonstrating the high light harvesting ability of the cylinder solar cells.

High performance PEDOT:PSS films prepared through a treatment with fluoro compounds and their application in polymer solar cells

Shizuyasu Ochiai, Kumar Palanisamy, Santhakumar Kannappan, Paik-Kyun Shin, Aichi Institute of Technology (Japan)

International concern about global warming and climate change due to emission of CO2 led to intense search for clean and renewable energy technologies such as photovoltaics. Polymer solar cells (PSC's) have received much attention as a promising clean and green energy

technology and the power conversion efficiency have steadily increased. There are several ways to improve the device efficiency of PSC, such as changing the active layer, insertion of the electron transport layer and the anode buffer layer. Among the several anode buffer layer materials, Poly(3,4-Ethylenedioxythiophene):Poly(styrene sulfonate) (PEDOT:PSS) is widely used as anode buffer layer due to its high transparency in the visible region, high thermal stability and mechanical flexibility. However, PEDOT:PSS suffers a problem of low conductivity and limits the device application.

In this report, we present the preparation of PEDOT:PSS hole transport layer through a secondary doping with flouro compounds such as hexafluoroacetone (HFA) and hexafluoroisoproponal (HIPA) with various concentrations by spin coating technique. High performance of the hole transport layer is attributed to preferential phase segregation of PEDOT:PSS with HFA and HIPA solvent mixture and solvent post treatment method. The improved performance of PSC was dependent on the structure of organic solvents and the concentration of flouro compounds in PEDOT:PSS solution. Using these optimized buffer layer, conjugated polymer solar cells with a Poly[[9-(1-octylnonyl)-9H-carbazole-2,7-diyl]-2,5-thiophenediyl-2,1,3-benzothiadiazole-4,7-diyl-2,5 thiophenediyl] polymer:[6,6]-phenyl-C71-butyric acid methyl esters (PCDTBT:PC71BM) bulk heterojunction have been produced on glass substrate. The obtained results show that PEDOT:PSS optimized with HFA and HIPA organic solvents can be a very promising candidate for transparent anode buffer layer in the low cost organic solar cell devices.

Fabrication and characterizations of PBDTTPD: PC71BM bulk heterojunction solar cell using air brush coating method

Shizuyasu Ochiai, Santhakumar Kannappan, Kumar Palanisamy, Jiro Tatsugi, Aichi Institute of Technology (Japan); Paik-Kyun Shin, Inha Univ. (Korea, Republic of)

Organic solar cells have attracted a significant amount of attention due to the need to develop an inexpensive clean and sustainable renewable energy source. We report on the fabrication of poly((4,8-diethylhexyloxyl) benzo([1,2-b:4,5-b?]dithiophene)-2,6-diyl)-alt-((5-octylthieno[3,4-c] pyrrole-4,6-dione)-1,3-diyl) /[6,6]-phenyl-C71-butyric acid methyl ester blend active layer using airbrush spray coating method in mixed solvents. The parameters such as spraying time, substrate-nozzle distance for the deposition of active layers were analysed. Optical absorption of the active layers was analyzed using UV-visible spectral studies in the wavelength range from 300 to 800 nm. The surface morphology of the active layers deposited with different parameters was examined using Atomic Force Microscopy. The current density-voltage (J-V) characteristics of photovoltaic cells were measured under the illumination of simulated solar light with 100 mW/cm2 (AM 1.5G) by an Oriel 1000 W solar simulator. We also notice that both the bottom-up and top-down approaches have played important roles in advancing our fundamental understanding of this new class of nanostructures. Finally we attempt to look into the future and offer our personal opinions on what the future trends will be in organic solar cell research.

Numerical modeling of time-resolved photocurrent in organic small-molecule donor-acceptor composites

Brian H. Johnson, Mark J. Kendrick, Oregon State Univ. (United States); John E. Anthony, Univ. of Kentucky (United States); Oksana Ostroverkhova, Oregon State Univ. (United States)

Organic donor-acceptor (D/A) heterojunctions have been a subject of intensive research, due to their potential applications in a wide variety of organic optoelectronic devices. Numerical modeling of processes occurring in organic D/A materials has been pursued in order to understand physics behind charge generation, transport, and recombination, which is important for further development of improved materials. We use a modified drift-diffusion model to numerically simulate time-resolved photocurrents in small-molecule bulk heterojunctions based on high-performance solution-processable functionalized anthradithiophene (ADT) and pentacene (Pn-R-F8) derivatives. (Here R is a side group which determines molecular packing in the solid state including the D/A separation at the D/A interface, without affecting optical and electrochemical properties of molecules themselves.) An ADT derivative was chosen as the donor, and Pn-R-F8 derivatives with various side-groups R served as acceptors. Composites with a fullerene acceptor PCBM were also studied. Thin films were deposited on glass substrates patterned with Au interdigitated electrodes, and the photocurrent under ~500 picosecond pulsed photoexcitation was measured with sub-nanosecond resolution, at various applied voltages. By fitting simulated time-resolved photocurrents to experimental data, we quantified charge photogeneration, mobility, and trapping rates in our D/A composites depending on the acceptor. Multiple relaxation paths occurring after photoexcitation were revealed, in particular: (i) direct photogeneration of free carriers, (ii) formation of donor-based Frenkel exciton, and (iii) formation of the charge transfer exciton state at the D/A interface. The contribution to photocurrent from each path is dependent on voltage, molecular packing, and the D/A separation at the D/A interface.

Transparent bifacial dye-sensitized solar cells based on organic counter electrodes and iodine-free electrolyte

Yaoguang Rong, Zhiliang Ku, Mi Xu, Linfeng Liu, Min Hu, Ying Yang, Hongwei Han, Huazhong Univ. of Science and Technology (China)

A transparent bifacial dye-sensitize solar cell (DSSC) was developed based on an organic counter electrode (CE) and an iodine-free electrolyte. For the highly uniform and transparent (transmittance > 90%) organic CE, poly(3,4-ethylenedioxythiophene) (PEDOT) film was prepared by electropolymerization of 2,2'-bis(3,4-ethylenedioxythiophene) (bis-EDOT) as the monomer on FTO glass substrate. For the iodine-free electrolyte, an ionic liquid (1, 2-dimethyl-3- propylimidazolium iodide, DMPII) was employed as the charge transfer intermediate without the addition of iodine. Due to the high transparence of the CE and non-absorption character of the iodine-free electrolyte, the bifacial device could not only yield a promising front-illuminated ? of 6.24%, but also produce an attractive ? as high as 4.38% for rear-side irradiation, which exceeds the rear-illuminated ? of 3.96% achieved for the same type of device, fabricated with the dark-colored iodine containing electrolyte. The transmittance of the CE and absorption of the electrolyte were evaluated by UV–vis spectroscopy. The electrocatalytic activity of the organic CE and the charge recombination rate of the devices were investigated by electrochemical impedance spectroscopy (EIS). This bifacial design for DSSCs presents promising prospect for façade applications.

Energy level control in D-A conjugated polymers: design and synthesis of new low band gap polymers containing thiophene and cyanovinylene units

Udaya K. Dalimba, Murali G. Maluvadi, National Institute of Technology, Karnataka (India)

Donor-acceptor (D?A) conjugated polymers have attracted a good deal of attention in recent years. In D?A systems, the introduction of electron

withdrawing groups reduces Eg by lowering the LUMO levels whereas, the introduction of electron donating groups reduces Eg by raising the HOMO levels. Also, conjugated polymers with desired HOMO and LUMO energy levels could be obtained by the proper selection of donor and acceptor units. Because of this reason, D?A conjugated polymers are emerging as promising materials particularly for polymer light emitting diodes (PLEDs) and polymer solar cells (PSCs)

We report the design and synthesis of four new narrow band gap donor-acceptor (D-A) conjugated polymers, PTCNN, PTCNF, PTCNV and PTCNO, containing electron donating 3,4-didodecyloxythiophene and electron accepting cyanovinylene units. The effects of further addition of electron donating and electron withdrawing groups to the repeating unit of a D-A conjugated polymer (PTCNN) on its optical and electrochemical properties are discussed. The studies revealed that the nature of D and A units as well as the extent of alternate D-A structure influences the optical and the electrochemical properties of the polymers. All the polymers are thermally stable up to a temperature of 300 oC under nitrogen atmosphere. The electrochemical studies revealed that the polymers possess low-lying HOMO energy levels and low-lying LUMO energy levels. In the UV-Vis absorption study, the polymer films displayed broad absorption in the wavelength region of 400?700 nm. The polymers exhibited low optical band gaps in the range 1.70 ? 1.77 eV.

Insights into electron and hole extraction layers for upright and inverted vacuum-deposited small molecule organic solar cells

Graeme M. Williams, Hany Aziz, Univ. of Waterloo (Canada)

Organic solar cells (OSCs) are studied for their photo-stability in inert atmosphere. Polymer solar cells with a bulk heterojunction (BHJ) of poly(3-hexylthiophene) (P3HT) and phenyl-C61-butyric acid methyl ester (PCBM) are contrasted with small molecule solar cells with a BHJ of metal phthalocyanine and C60-fullerene. A series of extraction layers are examined for their role in OSC performance and stability, including poly(3,4-ethylenedioxythiophene) poly(styrenesulfonate) (PEDOT:PSS), MoO3 and CF4 plasma treatment hole extraction layers (HELs), as well as LiF and bathocuproine (BCP) electron extraction layers (EELs). The inter-compatibilities of these extraction layers in polymer versus small molecule OSCs are explored. It is shown that the extraction layers commonly used in small molecule OSCs, CF4 plasma treatment and BCP, can be incorporated into polymer OSCs to achieve good performance. However, the commonly used polymer extraction layers, PEDOT:PSS and LiF, are generally less compatible with small molecule solar cells, resulting in either a slight reduction or complete removal of photovoltaic capabilities respectively. Through photo-aging studies, we show that interfacial extraction layers are necessary to avoid contact photo-degradation, which otherwise leads to strong reductions in OSC efficiencies. We also highlight certain extraction layer combinations that result in strong inter-electrode degradation. This inter-electrode degradation is shown to be exclusively due to thermal effects and is attributed to the release of moisture from PEDOT:PSS. The results highlight the need for the development of new extraction layer materials that serve to both enhance OSC efficiency, but are also resilient to light and heat treatments.

Monolithic all-solid-state dye-sensitized solar cells

Yaoguang Rong, Xiong Li, Zhiliang Ku, Mi Xu, Linfeng Liu, Min Hu, Ying Yang, Hongwei Han, Huazhong Univ. of Science and Technology (China)

The high cost of electricity produced by solar cells compared with electricity from other energy sources is an inhibitor to a more widespread adoption of solar energy. Here, a low-cost monolithic all-solid-state dye-sensitized solar cell (DSSC) was developed with a mesoscopic carbon counter electrode (CE). Based on the design of a triple layer structure, the TiO2 working electrode layer, ZrO2 spacer layer and carbon counter electrode (CE) layer are constructed on a single conducting glass substrate by screen-printing. With a vacuum pore-filling technique, solid-state materials such as PEO/PVDF polymer composite, poly(3-hexylthiophene) (P3HT) and spiro-OMeTAD hole transport material (HTM) could be effectively infiltrated into the multilayer thick films to assemble all-solid-state devices. The high surface area and large pore volume favor the penetration of the solid-state electrolyte materials and could reduce the resistance of the interface between CE and solid-state electrolyte. Correspondingly, efficiency up to 3.23% was obtained with polymer composite electrolyte, 2.62% with P3HT and 3.71% with spiro-OMeTAD hole transport material. This design for monolithic DSSC with a carbon CE presents a promising commercial application prospect.

OPV novel architectures for enhanced performance

Ahmed M. Farouk, RE Technologies (United States) and Boston Univ. (United States)

In practical photovoltaic systems, more than third of the light's energy is lost due to structural inefficiencies; irrespective of the active materials used. In conventional organic photovoltaics, for example, the insertion of light into the active material is very low. The compromise between optical depth and charge drift path reduces the external quantum efficiency. The use of transparent non-ideal electrodes reduces the charge extraction efficiency; in addition to many other shortcomings. In this paper, I propose a new device structure that eliminates most of these defects and almost doubles the practical efficiency limit of OPVs. It takes advantage of the recent advancements in the field of inkjet printing and the ease of handling organic semiconductors. The device eliminates the barriers between the active layer and the sun increasing light insertion into the active material. The new geometry de-couples the optical depth and the charge drift path. It also allows the utilization of better opaque ohmic electrodes that increase charge extraction. In addition, to several other improvements over the conventional OPVs, the new cell can be completely manufactured using only inkjet printing on, virtually, any substrate like wallpaper. The new structure is made flexible enough to assume various material configurations and to accept any number of stacked active layers. In this paper, the structural shortcomings are characterized. Several complex relations such as film thickness versus charge extraction are profoundly explored. The new device's operation and superior performance are illustrated. Also, a brief commercial viability study on the new cell is shown.

Multiscale analysis of effect of solvents on the P3HT-PCBM active layer

Min Huang, Manhua Liu, Tongji Univ. (China)

Solvents are often used in the active layer formation process in many photonic applications such as organic solar cell, organic led, organic wavelength conversion and photorefractive materials. In this contribution, multiscale modeling and simulation was used to reveal phase separation in P3HT-PCBM at mesoscale level due to attraction-repulsion between different organic functional groups of active ingredient molecules and solvent molecules. Force field parameters for mesoscale calculation were obtained from dynamic mapping of results from molecular dynamic simulations. DFT calculation was used to describe energy changes of active ingredient molecules due to surrounded residual solvent molecules. The simulation results from no solvent, chloroform, dichlorobenzene and chlorobenzene cases indicated that chlorobenzene exhibits strong attraction with fullerene of PCBM and strong repulsion with all the other functional groups, therefore leads to least phase segregation. DFT calculation showed that residual solvent molecules can slightly lower the energy but do not alter the value of band gap.

Study on the lifetime prediction of encapsulated organic solar cell under continuously varying environment

Namsu Kim, Kyungjoon Hwang, Sung Hyun Kim, Korea Electronics Technology Institute (Korea, Republic of); Samuel Graham, Georgia Institute of Technology (United States)

The lifetime of encapsulated organic solar cell under continuously varying environment was predicted based on total amount of permeated water permeated through barrier layers. Previous study (N. Kim et. Al., Solar energy materials & solar cells, Vol. 101, 140-146, 2012) presented the relation between the overall barrier performance and the shelf lifetime of encapsulated organic solar cells experimentally. Based on previous study, the total permeated water vapor through identical barrier layer under continuously varying environment can be calculated and compared to experimental data. For analytical calculation, diffusion and solubility coefficients were experimentally determined using quartz crystal microbalance as well as calculated based on previous experimental data.

8830-75, Session PWed

Study of aging behavior of carbon nanotube doped P3HT:PCBM organic solar cells

Ram P. Tandon, Vinamrita Singh, Swati Arora, Univ. of Delhi (India)

Introduction of various nano-materials in organic solar cells have shown to improve the device performance in terms of efficiency. However, stability and lifetime of organic photovoltaic still remains an issue of concern. We have investigated the effect of different carbon nanotubes on the optical and electrical properties of P3HT:PCBM thin films. These films were first optimized and then used as active layer in solar cells to study the degradation mechanism. Different concentrations of CNTs by wt. %age were added to P3HT:PCBM dissolved in chlorobenzene. Results of UV-Vis absorption spectra, photoluminescence spectroscopy and conductivity measurements showed that the optimum concentration of CNTs is 2%. An increase in absorption and quenching of emission spectra was observed with increase in CNT concentration. Conductivity of the order of 10-5 S/cm2 was achieved with CNT doping. The organic solar cells (ITO/PEDOT:PSS/P3HT:PCBM+CNT/Al) prepared with different concentrations of CNTs also confirmed that the cell with 2% concentration showed the best current-voltage characteristics. The aging behaviour of pristine and doped solar cells was studied in details by various techniques, and it was found that the degradation was lowered by CNT doping, which was compared by efficiency vs. time of the devices. Further, the degradation can be mainly attributed to the changes at the polymer/electrode interfaces.

Flexible organic solar cells with integrated grating structures

Roana Melina de Oliveira Hansen, Yinghui Liu, Morten Madsen, Horst-Günter Rubahn, Univ. of Southern Denmark (Denmark)

In the past years, organic solar cells have gained an increasing amount of attention due to their appealing properties such as mechanical flexibility, low weight, potential low cost and ease of processing. Recently, the power conversion efficiency of both polymer and small molecule solar cells has surpassed 10% and new materials and integration methods are continuously investigated for improving it further. One integration technique that is employed for increasing the solar cell efficiency is introduction of light-trapping structures within the cells, which leads to an enhanced light absorption in the organic thin-films.

In the work presented here, we report on development of flexible polymer solar cells with integrated diffraction gratings on the bottom electrodes. The presented results include P3HT:PCBM and PCPDTBT:PCBM solar cells, fabricated in an inverted geometry, that contains implemented grating structures whose pitch is tuned to match the absorption spectra of the different active layers. This optimized solar cell structure leads to an enhanced absorption in the active layer and thus improved short-circuit currents in the fabricated devices. Fabrication of the solar cells on thin polyimide substrates which are compatible with the lithographically processed grating structures are done in order to obtain the efficiency enhancement in thin, flexible devices.

Tin naphthalocyanine complexes for infrared absorption in organic photovoltaic cells

Richa Pandey, Ross A. Kerner, Univ. of Minnesota, Twin Cities (United States); Stephen Matt Menke, Univ. of Minnesota (United States); James R. Holst, Kanth V. B. Josyula, Sigma-Aldrich (United States); Russell J. Holmes, Univ. of Minnesota, Twin Cities (United States)

Typical single-cell bulk heterojunction (BHJ) OPVs are typically limited to an optical absorption within to visible spectrum (350-750nm). However, approximately 50% of the solar photon flux occurs at wavelengths greater than 750 nm. Several different types of materials have been used to extend the absorption in this infrared (IR) region of the solar spectrum. Herein, we investigated the use of Tin naphthalocyanine dichloride (SnNcCl2) as an electron donor material. SnNcCl2 is attractive in this capacity due to its low energy gap which leads to an optical absorption of greater 1100 nm. Simple bilayer devices with C60 as the electron acceptor material demonstrated a power conversion efficiency of 1.2% under simulated AM1.5G solar illumination at 100 mW/cm2. This result was compared with those of similar devices using Tin phthalocyanine (SnPc) as the donor material and it was found that the SnPc devices were dependent on dimer formation within the films for infrared absorption whereas SnNcCl2 owed its IR absorption to its extended conjugation within the molecule. A recent study has shown that Tin naphthalocyanine compounds can be further altered synthetically to tune the absorption characteristics. Consequently, it is expected that SnNcCl2 and materials of its ilk could be used in BHJ solar cells without exclusion of the infrared region.

8830-78, Session PWed

Influence of single regiodefects on the charge transport properties and microstructure of monodisperse, highly regioregular poly(3-hexylthiophene)

Carlo Tarantini, Univ. of Cambridge (United Kingdom); Christopher R. McNeill, Monash Univ. (Australia); Sven Hüttner, Univ. of Cambridge (United Kingdom); Michael Sommer, Leibniz-Institut für Polymerforschung Dresdene e.V. (Germany); Henning Sirringhaus, Univ. of Cambridge (United Kingdom)

Regioregular poly(3-hexylthiophene) (RR-P3HT) is a hole transporting material widely studied in polymer solar cells and organic field-effect transistors. Much research has been devoted to understanding the relationship between RR-P3HT film microstructure, charge transport behaviour and device operation. Here, aided by the synthesis of monodisperse, highly regioregular P3HT, we are able to systematically study the effect of regiodefects on charge transport and film microstructure. The properties of 'single-defect' RR-P3HT with one single tail-to-tail (TT) defect randomly located within a polymer chain, are compared with defect-free RR-P3HT of comparable molecular weight. Different molecular weights in the 7 kDa – 30 kDa range are studied.

Charge transport is studied via temperature-dependent Time-of-Flight measurements with spatial and energetic disorder parameters calculated within the Gaussian disorder model framework. The microstructure of RR-P3HT films with and without regiodefects is then probed using grazing-incidence wide-angle x-ray scattering (GIWAXS). We also examine the impact of thermal annealing protocols, and finally draw conclusions on the relationship between the presence of regiodefects, the inherent microstructural organisation of bulk RR-P3HT and its charge transport behaviour.

8830-79, Session PWed

Optimization of solution-processed merocyanine BHJ solar cells by the use of solvent mixtures

Martin R. Lenze, Klaus Meerholz, Univ. zu Köln (Germany)

The influence of casting from solvent mixtures on the performance of small molecule organic solar cells (SM-OSC) based on merocyanine (MC) dyes is investigated. Blends of the electron acceptor [6,6]-phenyl-C61-butyric acid methyl ester (PC61BM) and the MC dye EL86 have been spin cast from mixtures of chlorobenzene and different common solvents and have been employed in a simple bulk heterojunction setup of ITO/PEDOT:PSS/dye:PC61BM/Al. Solar cells with efficiencies as high as 3.0% could be obtained when using butanol as co-solvent to chlorobenzene. This improvement of 35%—compared to the device cast from pure chlorobenzene—is attributed to a change of the PEDOT:PSS work function. We show by Kelvin Probe measurements that the work function of PEDOT:PSS can be gradually increased up to 360 meV affecting all solar cell characteristics due to a more favorable energy level alignment with the low HOMO energy MC dye EL86. Consequently, the characteristics of OSCs based on other MC dyes could be improved as well. The energy level alignment itself will be subject of further investigations by photoelectron spectroscopy. It is worth mentioning that this effect on solar cell performance can only be observed when the alcohol is added to the spin casting solvent emphasizing the complexity of interface manipulation in solution processed OSCs. Further optimization of the device setup increases the power conversion efficiency of EL86 based devices to 4.0% under simulated AM1.5 illumination of 100 mW cm-2 and to 5.8% at reduced light intensities.

8830-80, Session PWed

Nano-biomaterials based on purple membranes and quantum dots

Sergei Y. Zaitsev, Evgeniy P. Lukashev, Daria O. Solovyeva, Pavel S. Samokhvalov, Alexander A. Chistyakov, Vladimir A. Oleinikov, National Research Nuclear Univ. MEPhI (Russian Federation)

The development of photosensitive nano-biomaterials engineered from biomembranes and semiconductor quantum dots (QDs) is a modern field at the interface of biophysics and bionanotechnology. Recent nano-bioengineering approaches employing QDs integrated with bacteriorhodopsin or purple membranes (PMs) permit the enhancement of the light-harvesting capacity of such systems, thus providing a strong impetus to the development of photovoltaic devices.

Here, we demonstrate advanced approaches to engineering of highly organized, oriented films from PMs of Halobacterium salinarum containing the photosensitive protein bacteriorhodopsin. Such ultrathin oriented PM films with QDs, covered with poly(ethylene glycol) (PEG) or cysteine (Cys), may be regarded as prototypes of hybrid nano-biomaterials with photovoltaic, energy transfer, and optical switching properties. Having compared different techniques for obtaining thin films with homogeneity and orderliness sufficient for industrial applications, we have shown that electrophoretic sedimentation provides the best results.

The particular differences of the photopotential parameters for the system PM-QDPEG or PM-QDCys as compared to the "individual" PM films were found. These changes in the photopotential values are correlating with the parameters of the bacteriorhodopsin photocycle that can be important advantage for the further materials application.

The biotechnological approach using site-directed mutagenesis permits fine adjustment of PM biophotovoltaic functionalities, thus enabling the development of hybrid nano-biomaterials with considerably improved functions useful for optical switching and photovoltaic applications.

Effects of molecular orientation on the energetics at the donor-acceptor interface and exciton transport in zinc phthalocyanine-based bilayer solar cells

Guy Oliver Ngongang Ndjawa, Kenneth R. Graham, King Abdullah Univ. of Science and Technology (Saudi Arabia); George Burkhard, Michael D. McGehee, Stanford Univ. (United States); Aram Amassian, King Abdullah Univ. of Science and Technology (Saudi Arabia)

Variation in molecular orientation in organic solar cells can lead to significant differences in power conversion efficiency. This work analyses how molecular orientation effects both the energetics and recombination rate at the donor-acceptor interface as well as exciton transport in Zinc Phthalocyanine (ZnPc) based bilayer solar cells. A thin 1 nm Copper Iodide layer at the anode was used to induce the change in orientation of the ZnPc molecules in the ZnPc active layer. GIWAXS/NEXAFS characterizations were performed on the ZnPc films to probe the molecular orientation. Devices with copper iodide showed a significantly higher power conversion efficiency (PCE) as compared to those without copper iodide (CuI). Charge Transfer state measurements were performed on ZnPc films and bilayer devices respectively and results show little difference in charge transfer state energies, suggesting marginal contribution of interfacial effects in the difference in performance. Ultraviolet photoelectron spectroscopy was also used to characterize the material and interfacial energetics for both orientations. Overall the results point towards exciton diffusion lengths accounting for most of the difference in PCE's.

8830-82, Session PWed

Optical modeling-based design and evaluation of inverted PTB7:PC71BM photovoltaics

Brent M. Valle, Case Western Reserve Univ. (United States); Stephen C. Loser, Northwestern Univ. (United States); Kenneth D. Singer, Case Western Reserve Univ. (United States); Tobin J. Marks, Northwestern Univ. (United States)

Further improvement of efficiencies in polymer photovoltaics is needed for commercialization and widespread adoption. Recent progress owes largely to the introduction of new donor materials with wide absorption ranges. Still, means of controlling and enhancing absorption without lowering open circuit voltages are highly desirable. In this work we present computational and experimental results of spectral sculpting enhancement of absorption and control using optical cavity effects. These effects increase absorption over a range of wavelengths that can be controlled simply by varying the bulk heterojunction (BHJ) or other layer thicknesses within the device.

Optical transfer matrix calculations were used to simulate absorption spectra within the BHJ layer. By varying BHJ and ZnO layer thicknesses, optimal and other interesting device architectures were determined. The active layer, a (1.0:1.5 wt) mixture of Poly[[4,8-bis[(2-ethylhexyl)oxy]benzo[1,2-b:4,5-b']dithiophene-2,6-diyl] [3-fluoro-2-[(2-ethylhexyl)carbonyl] thieno[3,4-b]thiophenediyl]] (PTB7) and [6,6]-phenyl C71 butyric acid methyl-ester (PC71BM) was selected for its large power conversion efficiency and large oscillator strength. Devices were fabricated in an inverted architecture: glass/Indium Tin Oxide (ITO)/ZnO/PTB7:PC71BM/MoO3/Ag to improve device stability and avoid relatively corrosive charge-selective layers. IV-curves and External Quantum Efficiencies (EQE) of cells were measured using a solar simulator (Sol2A, Oriel) and benchtop EQE setup (QEX10, PV Measurements Inc.) and then compared with transfer matrix theory. Strong agreement between simulated absorption spectra and EQE as well as power conversion efficiencies in excess of 7.5% for the optimal devices indicate the sound approach of using optical transfer matrix theory to optimize and shape absorption spectra in polymer photovoltaics.

8830-83, Session PWed

Organic solar cell degradation pathways: qualitative and quantitative imaging analysis

Roland Rösch, Marco Seeland, Technische Univ. Ilmenau (Germany); Yulia Galagan, Ronn Andriessen, Holst Ctr. (Netherlands); Martin Hermenau, Technische Univ. Dresden (Germany); Harald Hoppe, Technische Univ. Ilmenau (Germany)

We report about collaborative efforts on investigating the main degradation mechanisms of state-of-the-art organic small molecule and polymer solar cells by accelerated stability tests in combination with imaging analysis. Solar cells have been degraded under various stress conditions including elevated temperature and illumination under different light sources. Evaluation of devices was done by several imaging techniques such as luminescence imaging, lock-in thermography and light beam induced current, which are complemented by standard IV-characterization. Despite a qualitative interpretation of the different images yielding general knowledge about degradation pathways, quantitative analysis provides valuable additional information. Despite conventional and inverse polymer solar cell architectures, also evaporated organic photovoltaic devices were investigated. As main conclusion, the stability of to-dates organic photovoltaic devices remains dominantly limited by electrode degradation and the quality of the sealing, whereas intrinsic degradation of the organic photoactive layer plays only a minor role. This work provides guidelines for future improvements of stable organic solar cell device operation.

8830-84, Session PWed

Determination of thin film thickness by optical simulation and RBS techniques in flexible organic photovoltaic cells

Joseph Asare, African Univ. of Science and Technology (Nigeria)

This paper gives a computational analysis of thin film thickness using the “Optical” software with refractive index data and results from optical measurements of an Organic Photovoltaic (OPV) with Poly-3-hexylthiophene: [6, 6]-phenyl-C61-butyric acid methyl ester (P3HT:PCBM) as active layer, Polyethylene Terephthalate (PET) as substrate, ITO and Al as electrodes, and Poly (3, 4-ethylenedioxythiophene) Polystyrenesulfonate (PEDOT:PSS) as the hole transport layer. Easier deposition mechanism is employed in this research to fabricate this flexible multilayer structure. Rutherford Back Scattering (RBS) was used to confirm the ITO thickness simulated using the “Optical” Software to be 90 nm as compared to the latter’s ~100 nm result. This research also provides a guideline for mixing P3HT:PCBM which was the active layer used in fabricating the flexible Organic Photovoltaic cell in this research.

Extremely strong room temperature transient photocurrent-detected magnetic resonance in organic devices

Ying Chen, Rui Liu, Min Cai, Ruth Shinar, Joseph Shinar, Iowa State Univ. (United States)

An extremely strong room-temperature photocurrent (PC or IPC)-detected magnetic resonance (PCDMR) that elucidates transport and trapping phenomena in organic devices, in particular solar cells, is described. When monitoring the transient PCDMR in ITO/MEH-PPV/Al devices, where the MEH-PPV film was baked overnight at 100 C in O2, it is observed that |delta(IPC)/IPC| peaks at values >> 1, where delta(IPC) is the change in IPC induced by magnetic resonance conditions. Importantly, delta(IPC) and IPC are of different origin. The mechanism most likely responsible for this effect is the spin- dependent formation of spinless bipolarons adjacent to negatively-charged deep traps, apparently induced in particular by oxygen centers, to form trions.

Strain evolution of poly(3-hexylthiophene) crystals in a bulk-heterojunction thin film

Hyun Hwi Lee, Pohang Univ. of Science and Technology (Korea, Republic of); Hyo Jung Kim, Pusan National Univ. (Korea, Republic of)

In thin film devices, strain is inevitable and is related to the optical and electrical device properties. A comparison of inorganic and small molecule organic systems fabricated via thermal deposition techniques shows that strain in polymer thin films has not been extensively examined because such films are generally fabricated by solution processes. Polymer films that are thinner than the diameter of the unperturbed molecule, fabricated by spin-coating processes, display internal residual stress generated by rapid solvent evaporation.

In this work, we show that poly(3-hexylthiophene) (P3HT) crystals exhibit tensile strain in unannealed P3HT:PCBM blended films. The strain displayed different relaxation behavior during thermal annealing in the absence or presence of an Al electrode layer.

We obtained real-time lattice strain variations in the P3HT crystals via grazing incidence x-ray wide angle scattering measurements using in situ annealing equipment. The strain relaxation properties offered a plausible explanation for the better performance of organic photovoltaic devices based on annealed, as opposed to unannealed, P3HT:PCBM-based thin films. The main effects of annealing in a P3HT:PCBM system were to improve the phase separation of P3HT and PCBM, thereby forming better interpenetrating networks and to enhance the crystallinity of P3HT crystals. However, the enhancement was not prominent in this case. One aspect of the performance improvement is related to Al diffusion, which affects the distribution of P3HT crystals. This work suggests that the strain properties can also explain the improved device performance in the annealed system. The temperature-dependent strain properties depended on the annealing process in the presence and in the absence of an Al layer.

Rhenium oxide as an efficient p-dopant to overcome S-shaped current density-voltage curves in organic photovoltaics with a deep highest occupied molecular orbital level donor layer

Dae-Ho Kim, Jang-Joo Kim, Tae-min Kim, Seoul National Univ.

(Korea, Republic of); Won-Ik Jeong, LG Chem, Ltd. (Korea, Republic of)

One approach to improve the power conversion efficiency (PCE) of organic photovoltaic (OPV) cells is to use a donor with a low highest occupied molecular orbital (HOMO) level to increase the open circuit voltage (VOC) since the VOC is related to the energy gap between the HOMO level of the donor and the lowest unoccupied molecular orbital (LUMO) level of the accepter. However, when they are deposited directly on the indium tin oxide (ITO) anode, a large energy level difference between the workfunction (WF) of ITO and the HOMO level of the donor leads to an S-shaped current density-voltage (J-V) curve, reducing the fill factor (FF) and the PCE.

In this presentation, we inserted a p-doped hole transport layer (p-HTL)/intrinsic hole transport layer (HTL) bilayer between the ITO anode and the donor layer to remove the S-shape in the OPV cell. Effect of p-dopants in a p-HTL inserted between ITO and a donor layer of ?,?'-bis(2,2-dicyanovinyl)-quinquethiophene (DCV5T) with a deep highest occupied molecular orbital level is reported. Among the p-dopants of ReO3, MoO3, WO3 and CuI, ReO3 possesses the largest work function and turns out to be the most efficient p-dopant to remove the S-shape of the current density-voltage curve in the OPV cells. The rest of the dopants could not get rid of the S-shape, even with a doping concentration of 25 mol%. The difference among the dopants can be understood by the different charge generation efficiency of the dopants.

Microstructure-dependent photocarrier dynamics in pBTTT:PCBM blends

Andrew J. Ferguson, Nikos Kopidakis, Obadiah Reid, Garry Rumbles, National Renewable Energy Lab. (United States); Ester Buchaca-Domingo, Natalie Stingelin-Stutzmann, Imperial College London (United Kingdom)

The nature of the mixed phase in donor-acceptor bulk heterojunction (BHJ), blends of conjugated polymers and fullerene derivatives, has become an area of intense interest in recent years, particularly with respect to the relationship(s) between the microstructure, photophysical properties and device performance. We use time-correlated single-photon counting (TCSPC) and flash-photolysis time-resolved microwave conductivity (FP-TRMC) to probe exciton generation and dynamics; and carrier generation, transport and decay in a model BHJ system consisting of the thiophene-based conjugated polymer poly(2,5-bis(3-alkyl-thiophene-2-yl)thieno[3,2-b]thiophene)s (pBTTT) blended with the prototypical electron acceptor [6,6]-phenyl-C61-butyric acid methyl ester (PC61BM). We employ molecular additives to control the extent of mixing between the polymer and fullerene derivative, and correlate the photophysics with the induced microstructure. We demonstrate that by controlling the morphology of the intimately mixed phase and the pure polymer and fullerene domains we can influence the dynamics of generation and decay of photoinduced electrons and holes. Finally, we will discuss the results within the context of organic photovoltaic (OPV) device performance.

Pore filling of spiro-OMeTAD in solid-state dye-sensitized solar cells determined via optical reflectometry

Pablo Docampo, Andrew Hey, Univ. of Oxford (United Kingdom); Stefan Guldin, Univ. of Cambridge (United Kingdom); Robert D. Gunning, Univ. of Oxford (United Kingdom); Ullrich Steiner, Univ. of Cambridge (United Kingdom); Henry J. Snaith, Univ. of Oxford (United Kingdom)

A simple strategy is presented to determine the pore-filling fraction of the hole-conductor 2,2-7,7-tetrakis-N,N-di-pmethoxyphenylamine-9,9-spirobifluorene (spiro-OMeTAD) into mesoporous photoanodes in solid-state dye-sensitized solar cells (ss-DSCs). Based on refractive index determination by the film's reflectance spectra and using effective medium approximations the volume fractions of the constituent materials can be extracted, hence the pore-filling fraction quantified. This non-destructive method can be used with complete films and does not require detailed model assumptions. Pore-filling fractions of up to 80% are estimated for optimized solid-state DSC photoanodes, which is higher than that previously estimated by indirect methods. Additionally, transport and recombination lifetimes as a function of the pore-filling fraction are determined using photovoltage and photocurrent decay measurements. While extended electron lifetimes are observed with increasing pore-filling fractions, no trend is found in the transport kinetics. The data suggest that a pore-filling fraction of greater than 60% is necessary to achieve optimized performance in ss-DSCs. This degree of pore-filling is even achieved in 5 ?m thick mesoporous photoanodes. It is concluded that pore-filling is not a limiting factor in the fabrication of "thick" ss-DSCs with spiro-OMeTAD as the hole-conductor.

Copper(II) diphenylamine complex as photosensitizer on dye sensitized solar cells (DSSCs)

Ari H. Ramelan, Imas Badriyah, Sentot Budi Rahardjo, Univ. Sebelas Maret (Indonesia)

Copper(II) diphenylamine complex as photosensitizer on Dye Sensitized Solar Cells (DSSCs) had been investigated. The aim of this research is to find out the respond addition of dye copper(II) diphenylamine complex, addition of oxalate acid and oxalate sodium on FTO/TiO2 thin film to visible light and the effect of various concentration dye copper(II) diphenylamine complex to DSSC performance.

Slip casting method was used to fabricate FTO/TiO2 and FTO/carbon thin film. The result from FTO/TiO2 UV-Vis spectra show no absorption on visible light. Dye solution was synthesized from CuCl2.2H2O with diphenylamine ligands. UV-Vis spectrophotometry was used to identify FTO/TiO2/dye with various concentration, FTO/TiO2/oxalate acid/dye and FTO/TiO2/oxalate sodium/dye. The addition of oxalate acid and oxalate sodium on FTO/TiO2 thin film did not give significant effect. The result FTIR spectra of FTO/TiO2 and FTO/TiO2/dye show new absorption from aril-NH- group at 1315.45 cm-1 and absorption from C-N group at 1166.93 cm-1.

The performance of DSSC was determined by current curve and voltage method using Keithley 2602 A System Source. In this research, DSSCs are able to convert photon energy become electrical energy. The performance of DSSC on concentration 10-2 M and 10-3 M each produce efficiency 4.49x10-4% and 3.41x10-4% by light intensity 1447 Watt/m2 for 2 cm2 active area.

Advanced bio-sensitized photovoltaic cells based on oriented purple membranes and conducting polymers

Daria O. Solovyeva, Trinity College Dublin (Ireland) and National Research Nuclear Univ. MEPhI (Russian Federation); Pavel S. Samokhvalov, National Research Nuclear Univ. MEPhI (Russian Federation); Evgeniy P. Lukashev, Lomonosov Moscow State Univ. (Russian Federation); Vladimir A. Oleinikov, Sergei Y. Zaitsev, Alexander A. Chistyakov, National Research Nuclear Univ. MEPhI (Russian Federation); Igor R. Nabiev, Trinity College Dublin (Ireland) and National Research Nuclear Univ. MEPhI (Russian Federation) and Univ. de Reims Champagne-Ardenne (France)

Purple membranes (PMs) of the bacteria Halobacterium salinarum containing the photosensitive protein bacteriorhodopsin (bR) are promising for the development of bio-sensitized solar cells. PMs are photo-, thermo-, and chemically stable, may be dried or polymerized within the thick films and they have a high dynamic stability. The development of efficient PM-based bio-sensitized cells is a challenging task for fundamental research, nano-bioengineering, and photovoltaics.

We have engineered a solar cell based on thick films of PMs and a conducting mixture of poly(3,4-ethylenedioxythiophene) and poly(styrene sulfonate) polymers. Although bR-based solar cells have been known before, the novel combination of oriented PMs with these polymers, as well as careful selection of technological parameters and electrodes (ITO, Al, or Ni films) has ensured better photocurrent and photovoltage characteristics (0.5 nA, 6 V). Integration of the light-harvesting and energy-converting CdSe nanocrystals has been shown to additionally improve these characteristics. These improvement may be achieved due to (1) the capacity of nanocrystals for harvesting additional energy in the UV and visible regions of the solar spectrum, (2) the use of nanocrystals with diameters (and, hence, fluorescence colours) adjustable so that their fluorescence spectra considerably overlap with the bR absorption spectrum, and (3) advanced nano-bioengineering approaches to controlled coupling of nanocrystals with PMs ensuring a donor–acceptor distance significantly shorter than the Förster radius and efficient FRET to be occurred. The use of integrated energy-harvesting "nano-enhancers" capable of transferring additional energy to PM films and genetically engineered mutant bRs makes bio-sensitized solar cells competitive components of bioinspired photovoltaic devices.

Admittance analysis in (PPE-PPV) polymer (AnE-PVstat) light emitting diodes

Kubilay Kutlu, Orhan Ozdemir, Y?ld?z Teknik Üniv. (Turkey); Selin P. Mucur, Emine Tekin, TUBITAK UME (Turkey); Sameh Boudiba, Johannes Kepler Univ. Linz (Austria); Christoph J. Brabec, Linz Institute for Organic Solar Cells (Austria); Daniel A. M. Egbe, Johannes Kepler Univ. Linz (Austria); U. Deneb M. Yilmazer, Pelin Addogan Kavak, Y?ld?z Teknik Üniv. (Turkey)

Charge storage properties of anthracene-containing poly(p-phenylene-ethynylene)- alt - poly(p-phenylene-vinylene) (PPE-PPV) polymer (AnE-PVstat) light emitting diodes (OLED) devices were investigated through admittance measurement. Beginning of negative capacitance and light output of the device coincided at flat band voltage (1.8 V) or turn-on voltage, which was the difference of energy band gap of polymer and two barrier offsets between metals and polymer. The proposed analytical model, derived for space charge limited region, was successfull to explain the experimental observations of the present OLED device.

8830-93, Session PWed

Layer-by-layer all transfer based bulk-heterojunction solar cells with interfacial modification

Jung Kyu Kim, Wanjung Kim, Sungkyunkwan Univ. (Korea, Republic of); Dong Hwan Wang, Univ. of California, Santa Barbara (United States); Dae-Geun Choi, Korea Institute of Machinery & Materials (Korea, Republic of); Jong Hyeok Park, Sungkyunkwan Univ. (Korea, Republic of)

A novel cost- and time-effective vacuum free process to fabricate bulk-heterojunction (BHJ) organic photovoltaics (OPVs) via layer-by-layer selective stamping-transfer of all layers is described. By controlling the surface properties of polyurethane acrylate (PUA) stamping molds with UV-ozone exposure, PEDOT:PSS, BHJ layer and metal cathode were uniformly transferred layer by layer onto each of the bottom layers. Among several interfaces between each layer, we found that the interface between the active layer and metal cathode is a critical factor in obtaining conventional device like efficiency. To enhance the interfacial connectivity between the BHJ layer and metal cathode, titanium oxide (TiOx) interlayer was introduced. Cell performance was optimized by controlling the concentration of TiOx solution. The P3HT:PC60BM BHJ device fabricated by transferring PEDOT:PSS, TiOx /Active layer, and Al cathode showed 2.01% and the PTB7:PC70BM BHJ device fabricated by transferring TiOx and Al cathode showed 3.76% power conversion efficiency. This efficiency is not comparable with those of conventional OPVs, but our approach shows the possibility of fabricating OPVs via the layer-by-layer transfer method for the first time.

Methylammonium lead iodide perovskites/ fullerene planar-heterojunction hybrid solar cells

Tzung-Fang Guo, National Cheng Kung Univ. (Taiwan)

We report the fabrication of all-solid-state, methylammonium lead iodide (CH3NH3PbI3) perovskites/fullerene (C60), donor/acceptor planar-heterojunction (PHJ), hybrid solar cells. Spin-casting the ?-butyrolactone solution of methyl ammonium iodide and lead iodide forms a thin CH3NH3PbI3 perovskite film (20~30 nm) on the substrate. The deposition of a thin C60 (acceptor) layer in vacuum on CH3NH3PbI3 perovskite (donor) creates a hybrid PHJ for fabricating solar cells. CH3NH3PbI3 perovskite harvests the wide range of light from visible-to-near infrared and transports the positive charges. No additional hole-transport layer and mesoporous metal-oxide nanostructures for CH3NH3PbI3 perovskite are applied. The CH3NH3PbI3/C60 PHJ devices exhibits the promising photovoltaic performance of open-circuit voltage VOC = 0.55 V, short-circuit current JSC = 5.21 mA/cm2, fill factor FF = 0.57, corresponding to a power conversion efficiency (PCE) of 1.6% under standard 1 Sun AM 1.5 simulated solar irradiation. In addition, the magnitudes of VOC and PCE elevate to 0.65 and 0.75 V, 2.4 and 2.1 % using [6,6]-phenyl C61-butyric acid methyl ester (PCBM) and indene-C60 bisadduct (ICBA), respectively, whose lowest unoccupied molecular orbital (LUMO) level are higher comparing with C60 as the acceptor. These results suggest photovoltaic parameters of CH3NH3PbI3 perovskite/C60 or C60 derivatives PHJ are controlled by the level position offset of donor and acceptor. By the judicious selection of solvent (dimethylformaide) and deposition procedure for preapring CH3NH3PbI3 perovskite film, the hybrid device delivers a 3.0 % PCE with impressive 9.02 mA/cm2 in JSC. Our findings demonstrate the design rules and the possible development of newly structured, hybrid, efficient solar cells.

8830-95, Session PWed

Transferable graphene oxide of electron-transport layer for efficient bulk-heterojunction solar cells by stamping nanotechnology

Dong Hwan Wang, Univ. of California, Santa Barbara (United States); Jung Kyu Kim, Jong Hyeok Park, Sungkyunkwan Univ. (Korea, Republic of); Alan J. Heeger, Univ. of California, Santa Barbara (United States)

Transferable graphene oxide (GO) serves as an electron transport layer (ETL) in bulk heterojuction solar cells. The GO is inserted by stamping nanotechnology, with the help of a transfer film, on poly[N-9"-heptadecanyl-2,7-carbazole-alt-5,5-(4',7'-di-2-thienyl-2',1',3'-benzothiadiazole)] (PCDTBT):[6,6]-phenyl C71 butyric acid methyl-ester (PC71BM). The BHJ solar cells with the GO ETL exhibits improved short circuit current, JSC, and improved Power Conversion Efficiency, PCE, because of efficient electron transport from the BHJ layer to the Al cathode resulting in decreased series resistance and better charge

extraction compared to the device without GO layer. Moreover, solar cells with sequentially coated GO/titanium oxide (TiOx) ETL show a synergistic effect of increased electric field amplitude as inferred from optical simulation. Addition of the GO/titanium oxide (TiOx) ETL leads to the highest PCE of 7.5 %. The BHJ solar cells with GO ETL also exhibit long-term stability, comparable to that of TiOx. BHJ solar cells fabricated with the GO layer inserted by stamping transfer are promising as candidates for high performance devices because of the newly designed ETL which serves to reduce the electronic charge barrier.

Ring-protected small molecules for organic photovoltaics

Lianjie Zhang, Ashish Dubey, Swaminathan Venkatesan, Jianyuan Sun, Logan P. Sanow, Qiquan Qiao, Cheng Zhang, South Dakota State Univ. (United States)

Recently, excellent solar cell device performances have been achieved with solution-processed small-molecule donor materials. Small molecules have well defined structures and thus allow better control of self-assembly in the solid state. However, the easy formation of H-type aggregates and lack of strong interactions between nanodomains could limit charge transport, device performance, and long-term stability. We have recently explored the synthesis of ring-protected small molecules (with rings surrounding the center of the molecules), studied the intermolecular interactions in solution and solid state, and conducted preliminary solar cell device fabrications. It has been found that the molecules behave very differently from conventional flat small molecules in both solution and solid states. Proton NMR study of solutions of different concentrations revealed the presence of strong intermolecular interactions as a result of absence or shortage of open-ended alkyl side chains; however, such strong interactions do not lead to precipitation of the molecules even at high concentrations. Excellent films are routinely obtained from the neat small molecules despite the much reduced number of solubilizing groups. The New findings strongly suggest that ring protection is an effective strategy to avoid H-aggregation and maintain strong pi-pi interactions simultaneously. Such materials are expected to form head-tail self-assemblies that will embrace the advantages of both small molecules and polymers. More interestingly, thin films of such materials are potentially more isotropic in charge transport than conventional small molecule and polymer films, a property desirable for photovoltaics and some other optoelectronic applications.

8830-97, Session PWed

Benzo[1,2-b:4,5-b]dithiophene- and bithiophene-based ring-protected molecules for photovotaics

Lianjie Zhang, Jianyuan Sun, Logan P. Sanow, Cheng Zhang, South Dakota State Univ. (United States)

Solution-processable small-molecule donor materials have been intensively investigated for photovoltaic application. Small molecules have well-defined structures and thus allow facile self-assembly in the solid state. Various electron-withdrawing groups can be easily incorporated to tune energy gap and intermolecular interactions. Despite these advantages, self-assembly of small molecules in the solid state in principle produces more domain boundaries than polymeric materials and there is a lack of mechanism to connect the nanodomains to prevent hem from physically separating from each other. The intrinsic higher tendency for crystallization and higher molecular mobility may lead to continuous growth of nanodomains into micro crystallites. This could limit charge transport, device performance, and long-term stability. We have recently explored the synthesis of ring-protected small molecules (with rings surrounding the center of the molecules) based on widely used aromatic units such as benzo[1,2-b:4,5-b]dithiophene- and bithiophene, and investigated their potentials for photovoltaic application. With the presence of a ring to prevent molecules from forming H-aggregates, the amount of side chains can be reduced by 80% to allow strong pi-pi interaction to happen as revealed in NMR study in a likely head-tail fashion without causing any problem in solubility and film formation. It appears that that ring protection is an effective strategy to avoid H-aggregation and maintain strong pi-pi interactions simultaneously. Such materials are expected to self-assemble in a way that is different from both conventional small molecules and polymers, and likely form films that are more isotropic in charge transport than usual (self-assembled) organic materials.

Microscopic effects of an intermediate exciton blocking layer on the opto-electronic properties of diindenoperylene/C60 bilayer photovoltaic cells

Andreas Steindamm, Michael Brendel, Julius-Maximilians-Univ. Würzburg (Germany) and Bayerische Zentrum für Angewandte Energieforschung e.V. (Germany); Katharina Topczak, Julius-Maximilians-Univ. Würzburg (Germany); Jens U. Pflaum, Julius-Maximilians-Univ. Würzburg (Germany) and Bayerische Zentrum für Angewandte Energieforschung e.V. (Germany)

Interface effects play a dominant role in the performance of organic thin film devices. In the present case, we have analyzed molecular bilayer photovoltaic cells composed of the electron donor (D) Diindenoperylene (DIP) in combination with the electron acceptor (A) C60. These planar heterojunction cells have demonstrated overall efficiencies of up to 4 % [1]. Besides the rather poor absorption of the crystalline DIP layer due to its unfavorable orientation of transition dipoles with respect to the incident light, major limitations are imposed by exciton and charge carrier losses at the cathode interface. We address these questions by variations of the growth conditions and by the implementation of a Bathophenanthroline (BPhen) exciton blocking layer (EBL) between C60 and metal cathode. Complementary measurements of current density, external quantum efficiency, and photoluminescence quenching provide a detailed microscopic picture of the contributing loss processes. The experimental data obtained upon variation of the intermediate BPhen layer thickness between 0nm and 50nm indicated that Ag atoms of the top contact are able to penetrate the whole 35nm thick C60 film leading to exciton quenching already at the D/A interface if no blocking layer is applied. In contrast, for a 5nm thick BPhen EBL an optimal trade-off between exciton blocking, suppression of metal penetration and electron transport has been achieved, improving the overall device efficiency by a factor of two [2].

Hybrid cascade hole extraction layer composed of tungsten oxide/PEDOT:PSS to enhance long-term stability and power conversion efficiency of polymer solar cells

Wanjung Kim, Sungkyunkwan Univ. (Korea, Republic of)

In recent years, alternatives to poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS), which is used polymer solar cells (PSCs), have been actively researched because of its disadvantages such as hygroscopic and acid characteristics in terms of device stability. In order to address this problem, various solution-processable metal-oxide hole extraction layers (WOx, NiOx, MoOx) are studied as an alternative to PEDOT:PSS. However, there are still some problems to be addressed before metal oxides can replace PEDOT:PSS layers such as difficulty to control the work function of metal oxide films easiliy for applying to all donor polymers with different HOMO levels and low inital power conversion efficiency compared to devices with PEDOT:PSS.

Furthermore, PEDOT:PSS is still an attractive material due to its many advantages compared to metal oxides, such as good conductivity, low-temperature solution processability and proper work function that is well-matched with the HOMO energy levels of most donor polymers.

In this study, PSC devices are fabricated with a hybrid hole extraction layer (H-HEL) composed of tungsten oxide and PEDOT:PSS layers in order to determine the synergistic effects of hybridization. As a result, the device with a H-HEL showes better long-term stability in both P3HT:PC60BM and PTB7:PC70BM BHJ systems because the ultra-thin oxide layer effectively blocked indium diffusion from the etched ITO glass. In additon, power conversion efficiency of the device is slightly improved in two different P3HT:PC60BM and PTB7:PC70BM systems due to the increased JSC, which was caused by efficient hole extraction from the cascade energy level alignment of the H-HEL.

8830-100, Session PWed

Surface modification of Al-doped ZnO transparent electrodes for efficient carrier collection in organic solar cells

Grzegorz Luka, Institute of Physics (Poland)

The work function difference between electrodes is one of the crucial parameters that determine the performance or various organic electronic devices including organic solar cells. Aluminum-doped zinc oxide (AZO) films have lower work function comparing to indium tin oxide (ITO), which promotes their use as transparent electrodes in inverted organic solar cell devices. Additionally, by introducing magnesium into AZO films, a decrease of the conduction band minimum with respect to the vacuum level can be achieved. It enables an effective work function adjustment to an adjacent organic layer, which, in turn, can enhance the photogenerated and extracted charge carrier collection efficiency.

In this work, we applied atomic layer deposition (ALD) to grow AZO films with a very thin (a few nanometers) Zn1-xMgxO:Al layer grown on the top of the AZO film. The advantage of the ALD technique is its ability to grow very conformal films with the thicknesses controlled in the nanometer-scale. By changing the Mg content from $x = 0$ to $x = 0.4$, we observed the respective decrease of the work function of the films which resulted in the increase of the rectification properties of the organic single layer structures. We also show the influence of AZO transparent electrodes with Mg surface modification on the photovoltaic efficiencies of the test structures.

This work was partially supported by the European Union within the European Regional Development Fund, through the Innovative Economy grant (POIG.01.01.02-00-108/09).

Organic solar cells with Au-Ag nanowire electrode

Siddhartha Saggar, Predeep Padmanabhan, National Institute of Technology Calicut (India)

In an attempt to overcome the limitations of the presently prevailing transparent conducting electrode (TCE) – indium tin oxide (ITO) – many materials have been considered for replacing ITO. Recently, a novel method has been reported for the synthesis of Au-Ag NW mesh, and tested successfully for organic-light-emitting-diodes (OLEDs). It employs UV-induced reduction of gold- and silver- precursors to form Ag-Au Nanowire mesh. In this report, Ag-Au Nanowire mesh are formed on glass plate and employed as transparent anode for organic-solar-cell fabrication. The electrode showed good transparency and reasonable sheet resistance. The advantage of the technique is its simple processing method and cost-effectiveness.

8830-102, Session PWed

Review: novel silver nanowire mesh for transparent conducting electrode

Siddhartha Saggar, Predeep Padmanabhan, National Institute of Technology Calicut (India)

The purpose of this paper is to explain about a novel material for transparent conducting electrode (TCE) – mesh of silver nanowires (AgNW) – for organic optoelectronic application. With the transmission normalized over an area of the opening observed to be more than 100%, these materials have shown transmitivity higher than 90%, which is competitive with the conventionally used transparent conducting electrode – indium tin oxide (ITO). With good transparency and reasonably lower sheet resistance, these AgNW TCEs offer hope to various problems related to ITO use in such devices. In the article, various techniques of AgNW electrode fabrication are analyzed and comparative features are also provided.

Alkyl chain modification leading to enhanced OPV device performance in thieno[3,2-b] thiophene-diketopyrrolopyrole based polymers

Raja Shahid Ashraf, Iain Meager, Hugo A. Bronstein, Iain McCulloch, Imperial College London (United Kingdom)

Diketopyrrolopyrrole (DPP) unit was developed over four decades ago for high performance pigments. Owing to its strong absorption in the visible region and electron withdrawing nature it became a promising building block for small band gap conjugated polymers. When polymerized with electron-donating monomers, the resulting polymers show energy band gaps smaller than 1.5 eV. In recent years, there has been an intensive effort to develop polymers based on the DPP unit for photovoltaic applications; PCEs over 6% have been reported.

Recently, we have reported Thieno[3,2-b]thiophene-diketopyrrolopyrole (DPPTT-T) based polymers which led to PCEs of about 5.5%. To further tune optoelectronic properties of these polymers, we decided to alter the branching position of the solubilising chain on the DPP core. Moving the branching point away from DPP core, we were able to achieve high performing solar cells. Initial device performance of these polymers was above 7%. In depth studies of device performance in single junction devices, inverted and tandem solar cells will be presented.

8830-104, Session PWed

Performance improvement of dye-sensitized solar cells by surface patterning of FTO electrodes

Yu-Chao Wang, Chun-Pei Cho, National Chi Nan Univ. (Taiwan)

Patterned FTO electrodes for dye-sensitized solar cells (DSSCs) are fabricated by a facile wet etching method. The pattern depth can be controlled by altering etching time. FTO is thoroughly etched away when etching time is over 300s. Most DSSCs with patterned FTO electrodes exhibit both larger open-circuit voltage (Voc) and short-circuit photocurrent density (Jsc) as compared to the DSSC with unpatterned FTO electrode. The energy conversion efficiency of DSSC (n) gradually increases with increasing etching time and achieves a highest value when etching time is 240s. Then it drops abruptly as etching duration is longer than 240s. This indicates that an optimum pattern depth approximately 190 nm is required to acquire the best DSSC performance. The improved performance can be mainly attributed to enhanced light harvesting and light scattering due to larger amount of TiO_2 nanoparticles filled in the pattern and more dye adsorption. More contact between TiO_2

nanoparticles and patterned FTO with larger surface area is also an advantage. The sheet resistance of FTO dramatically increases when etching time is over 240s, and this can explain why device efficiency starts to reduce. It has been revealed from Nyquist plots that the charge transfer impedance at the TiO2/dye/electrolyte interface apparently influences the magnitude of Jsc as well as device performance. Electron transfer becomes easier and a higher n is thereby obtained when a DSSC has a smaller interfacial impedance. This study has demonstrated that there is obvious improvement in DSSC performance by surface patterning of FTO electrodes. With an appropriate etching condition, the highest n of 6.76% can be achieved, which is around 17% higher than that of the DSSC with unpatterned FTO electrode.

Charge generation and recombination in high open circuit voltage organic solar cells *(Invited Paper)*

David S. Ginger, Cody W. Schlenker, Kung-Shih Chen, Alex K. Y. Jen, Samson A. Jenekhe, Chang-Zhi Li, Liam Bradshaw, Hin-Lap Yip, Guoqiang Ren, Daniel R. Gamelin, Univ. of Washington (United States)

We demonstrate that modern high-performance organic photovoltaic (OPV) devices designed for solar energy conversion sometimes exhibit properties that appear to transcend historic design rules. We believe the reason for this lies in a balance between thermodynamic and kinetic factors that work together to control charge generation and recombination efficiency. For example, we find that the internal quantum efficiencies of photocurrent generation in poly(indacenodithiophene-co-phenanthro[9,10-b]quinoxaline):fullerene devices approach 100% despite the energy of the interfacial charge transfer state formed between the electron donor and the electron acceptor being higher than the energy of the donor triplet exciton in this blend. These results suggest that the kinetics of charge separation in well-optimized systems can outcompete charge recombination via the donor triplet, a process previously thought to limit photocurrent collection in high voltage devices. We define general features in the energy landscape that we believe to be critical for efficient photocurrent generation. We use a suite of spectroscopic techniques to identify new strategies for materials design aimed at controlling the kinetics of charge generation and recombination in these devices. We discuss the implications of our results for future device optimization by rational design.

8830-32, Session 7

Engineering energy transfer and exciton diffusion in organic semiconductors for application in photovoltaic cells

Stephen Matt Menke, Tyler K. Mullenbach, Kathryn A. McGarry, Christopher J. Douglas, Russell J. Holmes, Univ. of Minnesota, Twin Cities (United States)

Organic photovoltaic cells (OPVs) rely on the efficient dissociation of photogenerated excitons. In simple planar heterojunction OPVs, this dissociation occurs at an electron donor-acceptor interface, requiring the exciton to diffuse from the point of photogeneration in order to be harvested. This need for efficient exciton migration limits the performance of these cells, a limitation that is typically addressed through the use of bulk heterojunctions. We present an alternate approach that directly engineers the characteristic exciton diffusion length (LD) by optimizing the intermolecular separation and consequently, the photophysical parameters responsible for excitonic energy transfer. By diluting the electron donor boron subphthalocyanine chloride into a wide-energy-gap host, we optimize the degree of interaction between donor molecules and observe a ~50% increase in LD. The measured increase in LD is well-predicted using F?rster theory and separate measurements of material photophysics. Using this dilute-donor approach, we demonstrate planar heterojunction OPVs with a power conversion efficiency of 4.4%, >30% larger than optimized devices containing an undiluted donor layer. Interestingly, we have found that similar behavior is also observed in undiluted rubrene derivatives with a varying degree of steric bulk and hence also intermolecular separation. The dependence of LD on the intermolecular separation is again well-predicted using F?rster theory. In both of these cases, the clear correlation between LD and the degree of intermolecular interaction has broad implications for the design of OPV active materials and device architectures.

8830-33, Session 7

Energy level alignment and sub-bandgap charge generation in polymer:fullerene bulk heterojunction solar cells

Sai-Wing Tsang, Song Chen, Franky So, Univ. of Florida (United States)

Polymer solar cells with power conversion efficiencies (PCEs) over 8% have been demonstrated in laboratories with advances of novel materials, device processing, and device architectures. However, some critical physical properties of the polymer:fullerene bulk heterojunctions (BHJs) such as the donor-acceptor interface energetics which controls the charge transfer process are not well understood. In a BHJ photovoltaic cell, the open-circuit voltage (VOC) is determined by the energy level difference of the highest-occupied-molecular-orbital (HOMO) of the donor and the lowest-unoccupied-molecular orbital (LUMO) of the acceptor. However, there is lack of experimental approach to directly probe such alignment in a working device.

In this presentation, we will demonstrate a technique—charge modulated electroabsorption spectroscopy (CMEAS) to directly determine the effective bandgap and the interface effective force in a polymer:fullerene BHJ system.[1] By measuring the electroabsorption (EA) signal due to charge-modulation (CM) in the polymer, we are able to observe a clear sub-bandgap signal through direct excitation of excitons to the charge transfer states. Such a differential spectrum measured by CMEAS has a much higher signal-to-noise ratio than that measured by linear optical absorption techniques. Compared to the conventional electrochemical method, CMEAS can probe the energy level alignment at the electron donor-acceptor interface in a working BHJ photovltaic cell. Using CMEAS, for the first time we are able to directly probe the effective bandgap in polymer:fullerene systems. The results also bring insight into the details of the charge transfer states and the origin of VOC in polymer photovoltaic cells.

8830-34, Session 7

Charge transport and recombination in organic bulk-heterojunction materials in the in-plane direction *(Invited Paper)*

Ananth Dodabalapur, David A. Vanden Bout, Christopher J. Lombardo, Micah Glaz, Zien Ooi, Marlene Gutierrez, Oleksiy Slobodyan, Eric Danielson, The Univ. of Texas at Austin (United States)

Effective characterization of charge transport and recombination parameters in bulk heterojunction (BHJ) materials used in organic photovoltaic cells (OPV) is of vital importance for understanding how to increase the power conversion efficiency of these devices. These parameters, such as carrier mobility, carrier concentration, and the recombination coefficient have traditionally been successfully measured using vertical structures similar to OPV devices. Carrier mobility can be anisotropic in BHJ systems, particularly those used in high efficiency solar cells. We propose to characterize organic BHJ materials along multiple axes to measure the directional dependency of mobility and

measure isotropic parameters such as carrier concentrations and the recombination coefficient to obtain a more complete picture of charge transport within these materials. We have developed a lateral BHJ device which complements information that can be obtained from vertical structures by allowing the measurement of electrical properties along the transport direction of charge carriers. We employ several diagnostic methods with the lateral structures. One method involves the fabrication of several closely spaced voltage probes (fabricated by electron beam lithography) to perform in-situ potentiometry which yield valuable information about the recombination mechanisms and coefficient. The second method is based on scanning photocurrent microscopy which also yields information about the extent of the space charge layers from which several parameters can be extracted. We also present a numerical model to quantitatively understand and predict material properties from these lateral device measurements.

8830-35, Session 7

Molecular structure-dependent electron transport in fullerene acceptors for organic photovoltaics

Andrew J. Ferguson, Alex Nardes, Nikos Kopidakis, National Renewable Energy Lab. (United States)

The donor-acceptor bulk heterojunction (BHJ), blends of conjugated polymers and fullerene derivatives, has become the dominant and best-performing microstructure in organic photovoltaic (OPV) devices. In recent years sophisticated structural studies have identified a previously undetected phase consisting of intimately mixed polymer and fullerene molecules, although the importance of this phase to the photophysical and electrical performance of these systems is still a matter of debate. Furthermore, the rapidly advancing development of new high performance conjugated copolymers necessitates the design and synthesis of novel fullerenes with wider tenability than the available materials today. We use flash-photolysis time-resolved microwave conductivity (FP-TRMC), in conjunction with other spectroscopic and device-based techniques, to probe carrier generation, transport and decay in BHJs of various conjugated polymers and fullerene derivatives in an effort to address a) the importance of mixed polymer-fullerene phases and b) the electronic properties of new fullerene derivatives. We demonstrate that electron transport in the fullerene phase is dependent on both the molecular structure and fullerene domain size within the conjugated polymer “host”. We also explore the mixing of fullerene derivatives in both ordered and disordered polymer domains, and propose a mechanism for electron transport in these domains that correlates to the operation of organic photovoltaic devices.

8830-36, Session 7

Empirically based device modeling of bulk heterojunction organic photovoltaics

Adrien Pierre, Univ. of California, Berkeley (United States); Shaofeng Lu, Polyera Corp. (United States); Ian A. Howard, Max-Planck-Institut für Polymerforschung (Germany); Antonio F. Facchetti, Polyera Corp. (United States); Ana Claudia Arias, Univ. of California, Berkeley (United States)

We developed an empirically based optoelectronic model to accurately simulate organic photovoltaic (OPV) devices with novel materials. Bulk heterojunction (BHJ) OPV devices based on a new low band gap dithienothiophene-DPP donor polymer, P(TBT-DPP), is blended with PC70BM for various donor-acceptor weight ratios and solvent compositions. Photovoltaic devices produce power conversion efficiencies ranging from 1.8% to 4.8% at AM 1.5G. The mobilities of electrons and holes are determined using space charge limited current. Bimolecular recombination coefficients are both analytically calculated using slowest-carrier limited Langevin recombination and measured using an optical pump-probe technique. Exciton quenching efficiencies in the donor and acceptor domains are determined from photoluminescence spectroscopy. In addition dielectric and optical constants are experimentally determined. The simulation results using these physically measured parameters yield calculated photocurrent as a function of applied bias with less than 7% error for all devices. Free carrier generation and recombination rates of the photocurrent are modeled as a function of position in the active layer at various applied biases. These results show that while free carrier generation is maximized in the center of the device, free carrier recombination is most dominant near the electrodes even in high performance devices. Such knowledge of carrier activity is essential for the optimization of the active layer by enhancing light trapping while minimizing recombination. Our simulation program is intended to be freely distributed as a tool in laboratories fabricating OPV devices.

8830-37, Session 8

Optimization of low band gap polymer photovoltaics through structure modification and device engineering *(Invited Paper)*

Thomas P. Russell, Feng Liu, Yu Gu, Univ. of Massachusetts Amherst (United States)

For bulk heterojunction (BHJ) photovoltaic devices to realize commercial applications, effective strategies to maximize the performance have to be developed and fundamentally understood. In BHJ-type solar cells, the ability to control and optimize the active layer morphology is a critical issue to improve device efficiency, and this is usually achieved by optimizing the processing conditions, eg. using varied annealing procedures and choosing the right solvent additive. A family of structurally similar low band gap polymers were synthesized where their absorption can be tuned by the choice of monomer units. The morphology of these materials, and their blends with phenyl-C71-butyric acid methyl ester (PCBM) were characterized using x-ray scattering and electron microscopy methods. We observed that by using solvent additive, the morphology could be tuned to produce an interconnected polymer fibril network throughout the film. Details of this morphology, e.g. the inter-fibrillar distance and fibril dimensions are strongly affected by slight chemical structure modifications of the polymer. The best performance comes from the morphology with smaller fibril diameter and inter-fibrillar distance, which can only be obtained by combined processing and structural optimization. Using the conventional binary mixture approach for OPVs, these polymers (deep wavelength absorption) were mixed with short wavelength absorption conjugated polymer and further mixed with PCBM to form ternary blends to enhance the absorption. An enhancement in the device performance was observed and the multi-component thin film morphology was also characterized in detail.

8830-38, Session 8

Probing film structure in organic photovoltaic devices with neutrons

Paul L. Burn, Kwan H. Lee, Chen Tao, Paul Meredith, Ian R. Gentle, The Univ. of Queensland (Australia); Michael James, Australian Synchrotron (Australia)

The structure of the active film plays an important role in controlling the optoelectronic and device properties of organic solar cells. Neutron techniques such as neutron reflectometry (NR) and small angle neutron scattering are important methods for studying physical structures of (macro)molecules and their interactions non-destructively in solution and/or the solid state. In this presentation we will describe results from a time resolved NR measurement that enables the evolution of film structure to be followed. The polymer/fullerene films are generally produced by sequential deposition of the polymer followed by the fullerene, with a subsequent anneal. The structure of the films is then correlated to device performance.

8830-39, Session 8

The impact of polymer molecular weight and the degree of polymer-fullerene mixing on the performance of bulk heterojunction solar cells

Jonathan A. Bartelt, Stanford Univ. (United States); Jessica Douglas, Univ. of California, Berkeley (United States); William R. Mateker, Stanford Univ. (United States); Brian A. Collins, Harald W. Ade, North Carolina State Univ. (United States); Pierre M. Beaujuge, Jean M. J. Fréchet, King Abdullah Univ. of Science and Technology (Saudi Arabia); Michael F. Toney, SLAC National Accelerator Lab. (United States); Michael D. McGehee, Stanford Univ. (United States)

The relationship between polymer-fullerene bulk heterojunction (BHJ) morphology and solar cell performance is complex because both the composition and volume of each phase present in the BHJ play a role in determining device efficiency. Recent reports have shown that fullerene derivatives mix at the molecular level with conjugated polymers, but the role of the composition of the molecularly-mixed phase in these BHJ devices is not well understood. By tuning the composition of the molecularly-mixed phase in BHJ solar cells composed of the polymer PBDTTPD and PCBM, we find that 90% internal quantum efficiency is only attained if the concentration of PCBM mixed with PBDTTPD is above the percolation threshold needed for electron transport. If the concentration of PCBM mixed with PBDTTPD is too low, isolated PCBM molecules act as morphological electron traps and inhibit charge extraction from these BHJs. We also examine the effect of PBDTTPD molecular weight (MW) on BHJ morphology and solar cell performance and find that increasing the MW of PBDTTPD from 23 kDa to 39 kDa improves solar cell power conversion efficiency (PCE) from 4.0% to 7.9%. By thoroughly studying this effect, we elucidate that high MW PBDTTPD aggregates in solution, which leads to an increased degree of crystallinity in BHJs made with high MW PBDTTPD compared to those made with low MW PBDTTPD. This study highlights that both the composition of the molecularly-mixed phase and the degree of polymer crystallinity have drastic effects on BHJ solar cell performance.

8830-40, Session 8

Domain size, purity, and molecular orientation: critical parameters from soft x-ray scattering *(Invited Paper)*

Harald W. Ade, North Carolina State Univ. (United States)

Domain purity and interface structure are known to be critical for fullerene based bulk heterojunction solar cells, yet have been very difficult to study previously due to a paucity of characterization methods. Using novel soft X-ray tools, quantitative measurements of the domain purity and size, and a qualitative characterization of the nature of the structure of the donor/acceptor heterojunction (diffuse, sharp, interdiffused) can be achieved. Furthermore polarized x-ray scattering can reveal preferential orientation of the donor polymer (edge-on or face-on) relative to the bulk heterojunction interface. Such ordering has previously not been observed in fullerene-based solar cells and is shown here to be a critical factor for high performance.

8830-41, Session 8

Understanding the morphology and photophysics of PTB7 bulk heterojunction solar cells

Ifor D. W. Samuel, Gordon J. Hedley, Alexander J. Ward, Arvydas Ruseckas, Univ. of St. Andrews (United Kingdom); Alexander M. Alekseev, Univ. of Glasgow (United Kingdom); Calvyn T. Howells, Univ. of St. Andrews (United Kingdom); Luis A. Serrano, Graeme Cooke, Univ. of Glasgow (United Kingdom)

An important challenge in organic solar cells is to relate the photophysics and morphology to device operation in order to guide the development of improved materials. We have investigated this issue in the highly efficient polymer-fullerene (PTB7:PC71BM) blends. We present a comprehensive study of nanoscale phase separation, exciton dissociation dynamics into charge carriers and device, as well as a measurement of the exciton diffusion length in PC71BM. We find that in blends spin-coated from a solution without additives the fullerene molecules are segregated into pure 20-60 nm clusters which together form ~150 nm fullerene-rich domains. In these blends fullerene exciton dissociation into charge pairs occurs with an efficiency of 90%, yet the solar cell quantum efficiency (IQE) is only 40%, indicating that just 45% of charges are extracted. In contrast, blends spin-coated from a solution with a high boiling point additive form fibre-shaped alternating fullerene and polymer-rich domains which are <40 nm wide and 100-300 nm long in which fullerene excitons dissociate into charge pairs with an efficiency of 98%, with the device IQE reaching 80%. Our results indicate that charge extraction efficiencies with the additive is twice higher than without , and so we conclude that fibre-shaped phase domains are highly beneficial for OPVs because they give efficient charge extraction and minimise recombination.

8830-42, Session 8

In-situ x-ray scattering of solution-printed organic bulk heterojunction (BHJ) solar cells

Julia A. Reinspach, Ying Diao, Stanford Univ. (United States); Christopher J. Tassone, Stanford Synchrotron Radiation Lightsource (United States); Gaurav Giri, Stanford Univ. (United States); Michael F. Toney, Stefan C. Mannsfeld, Stanford Synchrotron Radiation Lightsource (United States); Zhenan Bao, Stanford Univ. (United States)

Organic bulk heterojunction (BHJ) solar cells consist of a blend of an electron-donating polymer and an electron-accepting fullerene, which form an interconnected network of three phases: a pure polymer, a pure fullerene, and a mixed fullerene-polymer phase. The performance of organic BHJ solar cells is, among other factors, highly dependent on the film morphology, such as molecular packing and the size of the respective phases. It is, therefore, not only crucial to understand how processing parameters influence the final film morphology, but also to gain a deeper understanding of the underlying physics of film formation.

In this contribution, we use synchrotron grazing-incidence small- and wide-angle x-ray scattering (GISAXS and GIWAXS) to study thin films of doctor-bladed organic BHJ's. We show how the molecular packing and phase separation can be controlled by the doctor-blading parameters (e.g., printing speed, solution concentration, solvent). To study the dynamics of BHJ film formation, we have developed a compact and portable doctor-blading setup for in-situ grazing-incidence x-ray diffraction (GIXD). The setup was used to monitor BHJ film morphology evolution, yielding in-situ GIXD data with a time resolution as high 0.3 s.

8830-43, Session 9

Light absorbing donor semiconducting polymers for organic solar cells *(Invited Paper)*

Iain McCulloch, Raja Shahid Ashraf, Imperial College London (United Kingdom)

Understanding the impact of both the organic semiconductor design and processing conditions, on both molecular conformation and thin film microstructure has been demonstrated to be essential in achieving the required optical and electrical properties to enable high efficiency organic solar cell bulk heterojunction devices fabricated from solution. Organic solar cell efficiencies are currently increasing rapidly based on organic bulk heterojunction devices fabricated from solution. Central to these device efficiency improvements are the development of new photoactive semiconducting donor and acceptor materials, designed at the molecular level to optimise both absorption of the long wavelength region of the solar spectrum and generation of high cell voltages. This presentation will examine some of the key design strategies to control the molecular orbital energy levels and microstructure of donor polymer semiconductors and illustrate with examples and their characterisation. Specifically, the systematic modification of the bandgap in a series of bridged ladder type indenofluorene copolymers through tuning molecular orbital energies with atom substitutions in the bridge position, will be illustrated. The impact of lowering the HOMO energy level on cell Voc, and the dependence of the Jsc on bandgap and morphology will be demonstrated.

8830-44, Session 9

Tailor-made absorber polymers for OPV: from synthesis to formulation development *(Invited Paper)*

Silvia Janietz, Alexander Lange, Eileen Katholing, Fraunhofer-Institut für Angewandte Polymerforschung (Germany); Wolfram Schindler, Helmholtz-Zenzrum Berlin für Materialien und Energie GmbH (Germany)

The introduction of adequate donor and acceptor units led to lower polymer HOMO energies for enhanced open circuit voltage in blends with PC70BM). In parallel, the copolymer band-gap was continuously reduced to improve matching of the polymer absorption with the sun spectrum, resulting in higher short circuit currents. Fluorene based terpolymers with different content of dialkyl substituted diphenyl-benzopyrazine or diphenyl-thienopyrazine and triphenylamine units (MR) were synthesized by Suzuki polymerization. The introduction of dialkyl substituted diphenyl-benzopyrazine for example in the fluorene main chain leads to LUMO-energy level of 3.1eV and in solar cells to an open circuit voltage of 0.96 V. Organic solar cells were prepared with inkjet printed consisting of the novel absorber polymer blended with PC61BM in a ratio of 1:2. Different solvent systems were used. It was found that devices prepared from the chlorine-free system showed only slightly lower efficiencies with respect to the chlorinated system, 2.5 as compared to 3.5%, respectively. Another synthetic concept includes the exchange of the fluorine unit through cyclopentadithiophene units in to the main chain to shift the absorption more in the IR. As the acceptor unit were chosen benzothiadiazole or fluorinated benzothiadiazole. Stille microwave coupling reaction was used for the synthesis of these polymers. Due to the strong impact of molecular weight on solar cell performance both polymers were synthesized with equivalent Mw and compared in blends with PC70BM.The exchange of the hydrogen against an flour atom on the benzothidiazole ring in the polymer chain causes the PCE to increase from 3,6 to 6,5 %.

8830-45, Session 9

Ionic high-performance light harvesting and carrier transporting OPV materials

Wouter Maes, Toon Ghoos, Jurgen Kesters, Wouter Vanormelingen, Laurence Lutsen, Jean Manca, Dirk Vanderzande, Univ. Hasselt (Belgium)

In the field of polymer solar cells, improving photovoltaic performance has been the main driver over the past decade. To achieve high power conversion efficiencies, a plethora of new photoactive donor polymers and fullerene derivatives has been developed and blended together in bulk heterojunction photoactive layers. Simultaneously, further optimization of the device architecture and interlayer effects is also of crucial importance. In this respect, we report on the use of specific types of electron transport materials, imidazolium-substituted polythiophenes, to boost the inherent I-V properties of polymer solar cell devices, resulting in a considerable gain in overall photovoltaic output (20% increase in PCE up to an average value of 6.2% for PCDTBT:PC71BM). The beneficial effect is notably higher than for previously reported materials such as an analogous trimethylamine-functionalized ionic polythiophene or PFN. Best results were obtained for the highest molecular weight ETL material, pointing to an important influence of polymer chain length on ETL performance. Further progress in this direction by structural variation (counterion, monomer ratio, (block) copolymer configuration, extension to CPDT-based low bandgap polymers) is reported as well.

8830-46, Session 9

The effect of sterics and intermolecular interactions at the donor-acceptor interface on the performance of organic photovoltaics

Kenneth R. Graham, Stanford Univ. (United States) and King Abdullah Univ. of Science and Technology (Saudi Arabia); Clement Cabanetos, Abdulrahman El Labban, Guy Oliver Ngongang Ndjawa, Pierre M. Beaujuge, Aram Amassian, King Abdullah Univ. of Science and Technology (Saudi Arabia); Michael D. McGehee, Stanford Univ. (United States)

Organic photovoltaics (OPVs) rely on the heterojunction between an electron donating material and electron accepting material to separate excitons into free electrons and holes. This interface is therefore critical to the performance of an OPV device, with the molecular conformation at this interface potentially playing a pivotal role in the charge separation and recombination dynamics. Although the molecular conformation at this interface is likely a determining factor in OPV performance, it remains relatively unexplored in most OPV systems. In this work we examine a series of benzodithiophene (BDT) and N-alkylthieno[3,4-c]pyrrole-4,6-dione (TPD) based copolymers, PBDTTPDs, with systematically varying sidechains. The variation of sidechains leads to significant differences in the morphology of bulk-heterojunction devices as probed through atomic force microscopy (AFM), transmission electron microscopy (TEM), and grazing incidence wide-angle X-ray scattering (GIWAXS). Although some variations in device performance may be ascribed to these nanomorphology differences, it appears that the sidechains also play a role in directing the molecular conformation between the polymer and fullerene. The effects of sidechains on the properties of the polymer-fullerene interface are explored through probing charge transfer state energies, with these results suggesting that the sidechains help to direct the molecular conformation at the polymer-fullerene interface. Furthermore, through making devices with low polymer concentrations in a fullerene matrix we are able to reduce the effects from nanoscale morphology variations, and these results further support a preferred molecular conformation that can be encouraged through appropriate sidechain substitutions.

8830-47, Session 9

Finely-tuning morphology of low band-gap polymer organic solar cells via mixed solvent

Jing Gao, Univ. of California, Los Angeles (United States); Wei Chen, Argonne National Lab. (United States); Gang Li, Yang Yang, Univ. of California, Los Angeles (United States)

Organic Photovoltaics have been gaining more and more importance in the energy field as a promising technology for low-cost, high-throughput, flexible energy generation process. In addition to materials novelty and device structure modification, morphology control of polymer: fullerene blend active layer is widely accepted as an efficient way for device performance improvement. Here, we report a new solvent mixture system for morphology tuning of diketopyrrolopyrrole (DPP)-based low bandgap polymer blended with PC71BM. Our study provides a new understanding of morphology control in organic bulk heterojunction.

Comparing to the widely used solvent system using 1, 8-diiodooctane (DIO) as additive, our solvent mixture system has significantly wider solvent composition window and higher degree of efficiency enhancement (25% in addition to efficiency acquired with DIO).We studied the conformational behaviors of DPP-based polymer and fullerene in the solution stage and during solid film formation stage in both solvent systems. Our results show that both solution state and film forming state morphology are important in determining the final bulk heterojunction morphology and they have distinct characteristics in both solvent systems. Thus the optimized performance is achieved via finely-tuning morphology through our solvent mixture system.

8831-101, Session 1

Industrial aspects of material development for organic field effect transistors *(Invited Paper)*

Klemens Mathauer, Paul van der Schaaf, BASF Schweiz AG (Switzerland); Jochen Brill, BASF SE (Germany)

It was in 1986, only a few years after the invention of an efficient synthesis of 3,6-diaryl-diketopyrrolopyrrole (DPP) that the term DPP (1) appeared in the pigment market. N,N-dialkyl-3,6-diheteroaryl-derivatives of DPP are suited as building blocks for conjugated polymers. This concept has been introduced for the first time in 2005. (2)

The presentation focuses on industrial aspects of the material development of DPP-Polymers for the application in solution processed field effect transistors. It will be shown that optimization of processing conditions can have a significant effect on transistor performance for a certain polymer. Although the solubility of DPP-Polymers is in general much higher than that of highly crystalline polymers like Poly-3-hexylthiophene (P3HT), transforming the polymer powder to a film is still challenging. Semiconductor film morphology and thus transistor performance strongly depends on it. Aspects of device integration, especially optimization of semiconductor interfaces to complementary materials, will also be discussed in this presentation.

8831-102, Session 1

Isoindigo-based copolymers for field-effect transistors: the structure-property relationship *(Invited Paper)*

Jian Pei, Peking Univ. (China)

Organic field-effect transistors (OFETs) are advancing rapidly in terms of their applications in low-cost large-area thin film transistors. However, PFETs with high carrier mobility and long-time stability are usually achieved in low-humidity and inert atmosphere. Therefore, to design new polymers for high-mobility PFETs with ambient-stability is still of great challenge. On the other hand, the structure-property relationship is important for designing new organic materials for optoelectronics. Although several design strategies and even computational methods have been proposed for small molecular OFETs, rational design strategy for PFETs is seldom reported.

Herein, we develop isoindigo-based copolymers for PFETs to investigate their structure-property relationship. Owing to the donor-acceptor interaction and the spatial steric hindrance caused by the branched alkyl chains, we envision that the small units dock into the cavity formed by the isoindigo cores and branched alkyl chains. We systematically compare FET device performances, polymer packing and film morphologies of the polymers, and find that this strategy is efficient to obtain high-performance FETs. Polymers with C2h-symmetric donors exhibit systematically higher field-effect mobility than those with C2v-symmetric ones.

8831-103, Session 1

V-shaped organic semiconductors having solution-processed high mobility and high thermal durability *(Invited Paper)*

Toshihiro Okamoto, Chikahiko Mitsui, Masakazu Yamagishi, Junshi Soeda, Yuri Hirose, Osaka Univ. (Japan); Takeshi Matsushita, JNC Petrochemical Corp. (Japan); Hiroyasu Sato, Akihito Yamano, Rigaku Corp. (Japan); Takafumi Uemura, Jun Takeya, Osaka Univ. (Japan)

Printed electronics for the next-generation smart devices require development of solution-processable high-performance organic semiconductors. However, despite the enormous versatility in designing organic molecules, practical industrialization has not been achieved using existing compounds such as a variety of acenes and heteroacenes because of the significant difficulty in realizing the high mobility, solubility, thermal stability, and large-scale productivity at the same time. Therefore, an essentially new molecular design that satisfies all of the above requirements is required. Here, we have developed a conceptually new Bent-shaped π-conjugated systems containing a heterocycle ring at the center of the cores.

We first developed a facile and versatile synthetic methodology for a series of bent-shaped derivatives. Specifically, starting from 2-methoxynaphthalenes, the compound is simply synthesized in four steps containing three key reactions. Interestingly, DNT–V itself exhibits a solubility of 0.10 wt% in toluene even at room temperature. These alkyl-substituted DNT–V derivatives exhibited improved solubility in common organic solvents in the range of 0.12–1.73 wt%. C6– and C10–DNT–VW having two hexyl (C6) or two decyl (C10) chains at the 3 and 9 positions exhibited the obvious phase-transition temperatures of 197 and 150 °C, respectively, which is considerably higher than the values for other reported organic semiconductors. Their overall packing structures are typical herringbone-type forms, which resemble those of high-performance semiconductors such as pentacene and DNTT solids. Such conformation may be induced by two-dimensional intermolecular interactions. Solution-processed films based on such molecules have demonstrated high mobilities of up to near to 10 cm2 V–1 s–1. In addition, the design introduces a soluble high-mobility π-conjugated core, and we describe a large-scale applicable synthetic route and pronounced thermal stability inherent in the V-shaped cores.

8831-104, Session 1

New type of organic semiconductors for high performance organic field-effect transistors

Hongxiang Li, Shanghai Institute of Organic Chemistry (China)

Great attentions have been paid to organic field-Effect transistors (OFETs) due to their potential applications in flexible displays, RFID, Smart cards, sensors, etc.[1] Organic semiconductors, as the key component of OFETs, are the base for high performance OFETs. Though great progress has been made, the lack of high performance organic semiconductors hinders the applications of OFETs.[2-3] Recently, we have developed series of high performance organic semiconductors.[4-9] We synthesized new type of thiophene based n-type organic semiconductors, the thin film transistors fabricated through solution technique exhibited high electron mobility (up to 0.9cm2/Vs) and high stability under ambient conditions. We also prepared a pentacene derivative which displayed high hole mobility, high current on/off ratio and low threshold voltage. In the presentation, these new results will be discussed.

Liquid crystalline polymers based on pi-conjugated backbone for organic electronics

Fabrice Mathevet, Univ. Pierre et Marie Curie (France)

The self-organization of pi-conjugated organic materials forming highly ordered supramolecular architectures has been extensively investigated in the last two decades in view of optoelectronic applications. Indeed, the control of both the mesoscopic and nanoscale organization within thin semiconducting films is the key issue for the improvement of charge transport properties and achievement of high charge carrier mobilities. These well-ordered materials are currently either self-organized semiconducting polymers or liquid crystals.

In this context, we endeavored to investigate the self-organization of a side-chain liquid crystal (SCLC) semiconducting polymer where (i) the backbone is a pi-conjugated polymer and (ii) the side groups are pi-conjugated discotic mesogens.

Here we describe the design and synthesis of columnar side-chain liquid crystal homo and alternating (co)polymers with triphenylene mesogens as side groups, and well-defined regioregular polythiophene as backbone.

These different kinds of architectures prepared following the Grignard methathesis (GRIM), allow the control of the triphenylene side group ratio along of the polymer chains, and lead to tunable electronic properties and nanostructures.

In this work, we will give the details on the synthesis, structural characterization and morphology studied by Polarized-light Optical Microscopy (POM), Differential Scanning Calorimetry (DSC), Temperature-dependent small-angle X-ray diffraction and Atomic Force Microscopy (AFM). Moreover, their photophysical properties and the preliminary charge transport results will also be depicted in view of applications for organic optoelectronics.

8831-106, Session 1

Molecular tuning for organic transistors *(Invited Paper)*

John E. Anthony, Marcia Payne, Matthew Bruzek, Sean R. Parkin, Univ. of Kentucky (United States)

The critical relationships between intermolecular contacts and performance in thin-film transistors have been known for more than a decade. Several different approaches to controlling and tuning these solid-state relationships have been developed in the ensuing years, leading to high-performance semiconductors adopting both “herringbone” and “π-stacked” motifs in the solid state. We have previously shown how peri substitution of acenes induces pi-stacking and allows coarse control over crystal packing. In this talk, I will show how further substitution can be used to induce subtle tuning in the intermolecular contacts, and the impact of these changes on device performance. I will also describe our efforts to engineer the solid state orientation of dehydroannulenes, a class of materials heretofore unexplored for use in organic transistors.

8831-107, Session 2

Analysis of charge traps related to bias-stress stability of organic transistors *(Invited Paper)*

Kilwon Cho, Pohang Univ. of Science and Technology (Korea, Republic of)

We investigated the actual position and energy level of charge traps which decide bias-stress stability in organic transistors. It is firstly demonstrated that the polymer chain-ends of polymer gate-dielectrics(PGD) can trap charges. The drain current decay and the threshold voltage shift are found to increase as the molecular weight (MW) of PGD decreases. It is due to the variation in the density of polymer chain-ends in the PGDs with different MW; the free volumes at the polymer chain-ends allow the residence of water molecules, which significantly increases the density of charge-trap sites. Secondly, we present a novel strategy for analyzing bias-stress effects based on a four-parameter double stretched-exponential formula (DSE) and a photo-excited charge collection spectroscopy (PECCS). DSE yields two characteristic times and two stretched-exponential factors, thereby separating out the respective contributions from charge trapping events in semiconductors and gate-dielectrics. We found that the gate-dielectric layer, in general, plays a more critical role than the semiconductor layer in the bias-stress stability in early stage, possibly due to the wider distribution of the activation energy for charge trapping. Furthermore, using PECCS, one of the direct probing methods for deep trap, we successfully quantified the profile of the density-of-states of charge traps, separating out the energy levels of bias-stress-induced charge traps influenced by the interface and the organic semiconductor.

8831-108, Session 2

Device physics of advanced DPP polymer based transistors *(Invited Paper)*

Ananth Dodabalapur, Taejun Ha, The Univ. of Texas at Austin (United States); Prashant M. Sonar, A*STAR Institute of Materials Research and Engineering (Singapore); Seohee Kim, The Univ. of Texas at Austin (United States)

Co-polymers based on the diketopyrrolopyrrole (DPP) acceptor block are very promising for use in field-effect transistor applications. Such polymers have been shown to possess mobilities in the range 2-10 cm2/V-s by a few groups (albeit at high operating voltages and in long channel length devices). In this presentation we will describe results with new DPP-based polymers and specifically discuss the device physics of low voltage (< 10 V) and small channel length (< 5 microns) devices. We have been able to obtain mobility values of ~4 cm2/V-s in such devices at low operating voltages for channel lengths of 4 microns. These devices possess very high temperature field-induced conductivity of any polymer FET and which exceeds that of most organic single crystal FETs. This research was a result of understanding how to control the deleterious effects of Fröhlich polarons which tend to reduce mobility when high-k dielectrics are used with polymer semiconductors. Employing a thin interfacial low k dielectric, we are able to get record high mobilities. These devices also possess very low off-currents and a high on/off current ratio. Charge transport data and mechanisms will be discussed in detail including a new comprehensive theory of transport in polymer FETs that includes molecular polaron, dielectric polaron, and defect trapping effects.

8831-109, Session 2

Organic thin-film transistors for circuits in a foundry: process, charge transport phenomena and device library

Sebastian Pankalla, Simone Ganz, Edgar Dörsam, Manfred Glesner, Technische Univ. Darmstadt (Germany)

For the development of circuits consisting of organic thin film transistors (OTFT) with satisfying yield, a stable and reliable process is necessary. This can be achieved by eliminating failure mechanisms and understanding the charge transport phenomena in the individual device. At first, we present an analytical closed-form solution of the OTFT channel potential used for Monte-Carlo charge transport simulations and compute current-voltage characteristics out of it. Second, the layer deposition process influences the layer interface morphology. Therefore, velocity distribution measurements of the charge carriers lead to a simulation model with different disorder, depending on the layer surfaces and deposition techniques. The influence of the Schottky barrier height and contact morphology is simulated by finite-elements. It could be verified that the charge injection limiting contact resistance can be decreased by two orders of magnitude by reducing the thin oxide layer at the source and drain contacts and improving the semiconductor layer morphology at their vicinity. At last, leakage currents through the gate dielectric can be described by a poor conducting semiconductor model in the finite-elements framework. Leakage currents increase power consumption in circuits and, what is more critical, can lead to a total failure of the OTFT. However, they can be influenced by the number of deposited dielectric layers and charge injection supporting self-assembled monolayers at the source and drain contacts. These findings lead to circuit building blocks for an organic device library whereupon still existing performance fluctuations can be coped with Monte-Carlo circuit simulations.

8831-110, Session 2

Charge injection layers in organic light emitting transistors

Kristen Tandy, Mujeeb Ullah, Paul L. Burn, Paul Meredith, Ebinazar B. Namdas, The Univ. of Queensland (Australia)

Light-Emitting Field-Effect Transistors (LEFETs) are a class of next generation devices that combine the switching capability of a transistor with the emission properties of a light-emitting diode. Current LEFET performance is limited by inefficient charge injection and transport of electrons and holes from the requisite source and drain electrodes, leading to unbalanced charge transport and hence poor device performance. Here we report a simple method to reproducibly fabricate interdigitated source and drain electrodes of different workfunctions (one low and the other high) to tune charge injection and transport. Single and bilayer LEFET devices have been fabricated in the bottom gate configuration with top contact source and drain electrodes and the model emissive organic semiconductor Super Yellow as the active channel material. A custom made set of complimentary shadow masks were used in combination to alternatively evaporate the hole-injecting and electron-injecting contacts and form interdigitated finger structures. Sequential evaporations were performed using the two shadow masks exchanged between the deposition of the anode and cathode in each case. This allows nm thin electron and hole injection layers to be used with interdigitated contacts in the LEFET device architecture. The masks and holder deliver fixed alignment, with the same channel dimensions formed each time. The source and drain electrodes consisted of two layers - a metal top layer, with a further thin injection layer in direct contact with the Super Yellow. The injection layer was varied and included metals such as Ca, Ba and Sm, organic materials such as TPBI (1,3,5-tris(N-phenylbenzimidizol-2-yl)benzene), metal oxides (molybdenum oxide) or a salts such as Cs2CO3.

We show a high EQE of 1.2% with ON/OFF ratios of > 103 for single layer devices. For bilayer devices, we obtained a peak EQE of 0.05% and ON/OFF ratios of order 105 with a brightness of ~100 cd/m2. This is the highest optical light output with electrical switching performance obtained so far from single and bilayer LEFETs using a fluorescent material. In this presentation we will report the LEFET fabrication strategy, characterization of the devices, and in-depth analysis of the mechanism of operation.

8831-111, Session 2

Confocal photoluminescence microscopy for the study of exciton quenching in organic field-effect transistors

Stefano Toffanin, Wouter A. Koopman, Marco Natali, Stefano Troisi, Raffaella Capelli, Viviana Biondo, Andrea Stefani, Michele Muccini, Istituto per lo Studio dei Materiali Nanostrutturati (Italy)

Organic light-emitting transistor (OLET) is a novel multifunctional organic optoelectronic device which is gaining interest within the academic community as well as in industry. This unique device integrates the properties of a transistor with light generation. Even though recent breakthrough in OLET electroluminescence efficiency, little is known on how the device architecture influences the light formation processes. An increased internal efficiency compared to organic light-emitting diodes (OLED) is motivated by the shifting of the position of the charge emission zone faraway from the injecting contacts, thus avoiding exciton dissociation at the metal electrodes. Moreover, the high charge densities at the semiconductor-insulator interface potentially increase the obtainable exciton densities, which is a prerequisite for the realization of intense nanoscale light sources. On the other hand, high charge-densities also can result in enhanced exciton-quenching. For the further development of the OLET, it is of crucial importance to obtain information how the transistor architecture influences the light generation.

Here, we discuss an innovative and high-throughput experimental method for studying locale differences in exciton quenching within field-effect transistor active channel by implementing a confocal laser scanning fluorescence microscope upgraded for spatially localized lifetime measurements. Our results show that the quenching is dominated by polaron-exciton scattering, while electric-field mediated dissociation plays only a role at the proximity of electrodes. Indeed, photoluminescence quenching can be implemented in an active transistor for probing the induced charge distribution and estimate layer-thickness. In real ambipolar OLETs it is possible to correlate directly the recombination zone with the light-emission zone.

8831-112, Session 3

Exponential relation of PBTTT liquid crystalline correlation length with device performance *(Invited Paper)*

Harald W. Ade, North Carolina State Univ. (United States)

Bond anisotropy and orientation are critical parameters that strongly influence the electronic properties of many polymer-based devices, such as poly(2,5-Bis(3-alkylthiophen-2-yl)thieno[3,2-b]thiophene (PBTTT) thin film transistors. This is directly related to the high mobility along the one-dimensional back bone, some mobility along the pi-pi stacking direction, and very low mobility along the lamellar direction. To date, ordering in active layers of devices could only be characterized with X-ray or electron microscopy methods if the sample exhibited sufficient crystallinity. Here, we show that resonant scattering with polarized soft x-rays (P-SoXS) is not limited by the crystallinity in soft matter and can probe ordering of molecular orientation down to size scales below 10 nm [1]. We utilize its high sensitivity to probe the length scale of liquid crystalline ordering in PBTTT transistors. We find that charge mobility is exponentially dependent on the liquid crystalline correlation length. This correlation length relates more closely to device performance than other characteristics as probed by wide angle x-ray diffraction. We are in the

process of measuring the correlation length with P-SoXS for other high mobility materials and will present initial results. – We thank I. McCulloch and M. Heeney (Imperial College, UK) for providing the PBTTT.

8831-113, Session 3

Solution coating aligned single-crystalline domains of strained organic semiconductor thin films *(Invited Paper)*

Ying Diao, Benjamin Tee, Stanford Univ. (United States); Stefan C. Mannsfeld, Stanford Synchrotron Radiation Lightsource (United States); Zhenan Bao, Stanford Univ. (United States)

Solution coating of organic semiconductors has a great potential for achieving low cost manufacturing of large area and flexible electronics. During the coating process, crystalline thin films of organic semiconductors are usually formed under kinetic conditions driven by the rapid solvent evaporation needed for high-throughput industrial-scale production. Yet, highly kinetic crystallization poses challenges to the control of thin film morphology. Two commonly encountered problems are mass-transport-limited crystal growth and uncontrolled nucleation. Both phenomena severely limit the electrical performance of organic semiconductors by introducing randomly distributed grain boundaries and structural defects. To address these challenges, we introduce a new approach for controlling morphology of solution printed thin films, wherein we design and engineer the fluid flow to enhance crystal growth and to control nucleus formation. We demonstrate for the first time a fast direct coating of patterned, millimeter-wide, centimeter-long, highly-aligned single-crystalline organic semiconductor thin films. Such a film morphology enabled an unprecedented average mobility of 8.1 ± 1.2 cm2 V-1 s-1 from lattice-strained single-crystalline domain thin films of 6,13-bis(triisopropylsilylethynyl) pentacene (TIPS-pentacene), with the maximum mobility reaching 11 cm2 V-1 s-1. This is also the first report of lattice-strained single-crystalline domain organic semiconductors achieved via solution processing.

8831-114, Session 3

Correlation between local morphology and electronic states in organic field-effect transistors investigated by charge modulation microscopy

Nicola Martino, Istituto Italiano di Tecnologia (Italy) and Politecnico di Milano (Italy); Calogero Sciascia, Alessandro Luzio, Istituto Italiano di Tecnologia (Italy); Valerio D'Innocenzo, Istituto Italiano di Tecnologia (Italy) and Politecnico di Milano (Italy); Maria Rosa Antognazza, Mario Caironi, Istituto Italiano di Tecnologia (Italy)

The morphology of the thin active layer is one of the main parameters that influence charge transport properties and thus the functioning of organic field-effect transistors (OFETs). To understand this relationship, it is desirable to have techniques able to locally probe the electronic properties along the channel of a working device. In this contribution we show that with Charge Modulation Microscopy (CMM)[1] it is possible to optically map the charge density in a high-mobility n-type OFET with a lateral resolution of about 500 nm; this is achieved by measuring the local polaronic absorption and bleaching features in a laser scanning confocal microscope. Interestingly, the signal is sensible only to the few-nanometers thick accumulation layer, allowing the investigation of the properties of the electronic states at the semiconductor-dielectric interface involved in charge transport processes. By using a polarized light probe, we highlight the presence of a micrometric texture in the map of the charge induced features, which can be related to regions of preferential alignment of the polymeric backbones. These regions of preferential alignment could play a crucial role in the transport properties of polymeric semiconductors, especially in novel n-type high-mobility materials in which the influence of morphology at different scales is currently highly debated.

8831-115, Session 3

Alkyl chain size and branching point influence over microstructure, morphology and charge transport in thieno[3,2-b]thiophene-diketopyrrolopyrole based polymers

Iain Meager, Imperial College London (United Kingdom)

Diketopyrrolopyrole (DPP) based polymers are well established as high performing materials in both solar cell devices and field effect transistors (FET). The electron deficient nature of the DPP core is desirable for donor-acceptor type polymers utilising molecular orbital hybridisation as a means to frontier orbital band gap reduction, with the planarity of the polymer backbone giving a good degree of pi-pi stacking.1 Solar cell devices fabricated from such materials have achieved efficiencies of >6%, whilst transistor mobilities routinely surpass 1cm2/Vs as demonstrated with the excellent results recorded in our group.2,3

Much effort has been dedicated to the fine-tuning of the electronic properties of such polymers yet the role of the solubilising alkyl chain is often overlooked. Herein is presented an extension of our group's work on thieno[3,2-b]thiophene-diketopyrrolopyrole (DPPTT-T) based polymers. By using larger chains and moving the branching position of the solubilising group on the DPP core higher molecular weight polymers are achieved and a larger range of comonomers can be accessed. Thus it is possible to selectively influence physical properties such as solubility and blend morphology whilst retaining the desirable energetic and optical characteristics previously achieved resulting in impressive and balanced transistor mobilities. The series of polymers are probed using state of the art diffraction, imaging and stability studies.

8831-116, Session 3

Recrystallization kinetics in polythiophene thin films and implications for charge transport

Duc T. Duong, Stanford Univ. (United States); Victor Ho, Univ. of California, Berkeley (United States); Sonya Mollinger, Stanford Univ. (United States); Michael F. Toney, SLAC National Accelerator Lab. (United States); Rachel A. Segalman, Univ. of California, Berkeley (United States); Alberto Salleo, Stanford Univ. (United States)

Semiconducting polymers have been increasingly exploited for their potential in low-cost, solution processable electronic applications such as field-effect transistors (FETs) and light-emitting diodes (LEDs). In these devices the polymers are often casted from an organic solvent to form thin films on the orders of tens and hundreds of nanometers. However, a large number of deposition parameters can impact the final film morphology and the solvent-polymer interaction is extremely system-dependent. One method for circumventing this large parameter space is to melt and recrystallize the polymer film, which essentially removes all solvent history.

In this study we perform quantitative analyses of x-ray diffraction patterns and optical absorption spectra of poly(3-ethylhexylthiophene) (P3EHT) thin films. Here P3EHT is used for its slow crystallization kinetics, which is a rare property among semiconducting polymers. We are able to monitor the evolution of aggregates and crystallites as well as the recrystallization kinetics as a function of time. One of the unique aspects of semicrystalline, semiconducting polymer is that crystallites are highly anisotropic: the three directions of molecular order are (1) along the polymer backbone, (2) along the pi stacks and (3) along the alkyl stacking direction. As such we expect crystallite growth to also be anisotropic and this is indeed what we observe from our experimental results. Furthermore, we are able to comment on the mechanism with which the entire film recrystallizes and how film thickness and quenching temperature influence the crystallization kinetics and final film morphology. Finally the extracted structural properties are correlated to charge transport.

8831-117, Session 4

Ultra low-noise transport regime in organic molecular crystals *(Invited Paper)*

Vitaly Podzorov, Rutgers, The State Univ. of New Jersey (United States)

Small-molecule organic semiconductors form the basis for the emerging field of organic optoelectronics. In order to better understand the intrinsic photo-physical and transport phenomena in this important class of materials, it is necessary to study samples of very high structural order and chemical purity. Such materials exist in the form of molecular single crystals that can be used for fabrication of high-performance prototype devices, such as field-effect transistors, photo-conductors and photo-voltaic cells, in which intrinsic properties of organic semiconductors can be investigated without parasitic effects of disorder (see, e.g., [1,2,3]). This talk will present a novel method of surface functionalization that results in an extremely low-noise charge transport regime at the surface of molecular crystals, leading to an observation of unprecedentedly clean and quiet (low-noise) Hall effect.

8831-118, Session 4

Transport in single crystal OFETs *(Invited Paper)*

C. Daniel Frisbie, Univ. of Minnesota (United States)

OFETs based on single crystals afford good opportunities to examine fundamental connections between charge mobility, molecular structure, and crystal packing. A particularly exciting recent development is the increase in the number of single crystal materials that exhibit OFET mobilities near 10 cm2/Vs, and also band-like behavior in that mobility increases as the device temperature decreases (up to a point). Observation of such large mobilities suggest that in these systems the intrinsic mobility is approached. In the first part of this talk will describe single crystal OFET measurements on a series of rubrene derivatives that have been designed so that the unit cell parameters are systematically tuned. The impact of the crystal structure on carrier mobility and the temperature dependence will be discussed. The second part of the talk will focus on transport in single crystal OFETs based on DNTT, a promising new organic semiconductor molecule that exhibits mobilities nearly as good as rubrene, the current benchmark material.

8831-119, Session 4

Light-emitting polymer/carbon nanotube hybrid transistors: below and above the percolation limit *(Invited Paper)*

Jana Zaumseil, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany)

Hybrids of semiconducting polymers and single-walled carbon nanotubes (SWNT) are interesting for organic electronic devices such as solar cells, light-emitting diodes and field-effect transistors (FETs). They are easily produced by selective dispersion of SWNTs in polymer solutions by ultrasonication followed by centrifugation. We demonstrate that nanotubes at concentration levels well below the percolation limit significantly improve charge injection of both holes and electrons into semiconducting polymers in top-gate FETs. This leads to lower contact resistances and reduced threshold voltages, thus the maximum ambipolar currents and visible light emission due to electron-hole recombination are considerably enhanced. This effect can be maximized by patterning layers of pure carbon nanotubes onto the injecting electrodes before spincoating the pristine polymers leading to almost ohmic contacts for polymers, which usually exhibit highly Schottky barrier-limited injection. This improved injection of holes and electrons allows for a much wider range of accessible polymers for ambipolar and light-emitting transistors.

The same conjugated polymers can also be used to enrich specific semiconducting SWNT and to produce high-performance ambipolar nanotube network FETs. These show unusually efficient near-infrared emission. The obtained electroluminescence spectra show clear peaks depending on the enriched nanotube species but with a strong shift of intensity to SWNTs with longer emission wavelengths, i.e., larger diameters, compared to photoluminescence spectra of the same area. Mapping the emission from these networks during a gate voltage sweep allows us to visualize preferential current paths and investigate percolation models for purely semiconducting SWNT networks.

8831-120, Session 4

Nonvolatile transistor memory devices using high dielectric constant polyimides electrets

Ying-Hsuan Chou, Hung-Ju Yen, National Taiwan Univ. (Taiwan)

We report the nonvolatile memory characteristics of pentacene-based organic field-effect transistors (OFET) using high dielectric constant polyimide electrets, , PI(6FDA-TPA-CN), PI(DSDA-TPA-CN) and PI(BTDA-TPA-CN), consisted of electron-donating 4,4?-diamino-4?-cyanotriphenylamine (TPA-CN) and different electron-accepting dianhydrides. The dielectric constants of PI(BTDA-TPA-CN), PI(DSDA-TPA-CN), and PI(6FDA-TPA-CN) are 3.44, 3.52, and 3.70, respectively. Among the polymer electrets, the OFET memory device based on PI(6FDA-TPA-CN) exhibits the highest OFET mobility of 0.5 cm^2* V^-1* s^-1 due to the formation of the large grain size of the pentacene film by the hydrophobic surface. The OFET memory devices with the configuration of n+Si/SiO2/PI/Pentacene/Au show excellent nonvolatile behaviors for bistable switching. The stability for ON and OFF state can maintain 10^4 s with Ion/Ioff current ratios of 10^4 for PI(6FDA-TPA-CN). Moreover, the higher dipole moment and larger torsion angle result in the more stable charge transfer complex and accompany with the largest memory window of 84 V of the fabricated device. The write-read-erase-read (WRER) cycles can be operated over 100 cycles. The present study suggests that the high dielectric constant polyimide electrets with the enhanced capabilities for transferring and storing the charges have great potential applications for advanced OFET memory devices.

8831-121, Session 5

Synthesis and transport properties of new polymeric semiconductors *(Invited Paper)*

Antonio F. Facchetti, Polyera Corp. (United States)

Organic electronics is a new technology envisioning the fabrication of electronic devices using printing methodologies instead of conventional photolitography employed in the silicon industry. Since polymeric materials can be printed more efficiently than small molecules (they can be more easily formulated into inks with tuned viscosities) they will be the key enablers of this technology. In this presentation I will describe the design rationale, synthesis, characterization, and electrical properties of several new semiconducting polymers for printed thin-film transistors (TFTs). These polymers include new n-channel polymeric semiconductors containing dicarboximide functionalities, p-channel semiconductors based on new electron-neutral cores, and ambipolar polymers base on pi-extended monomers. This work demonstrates that printed TFTs are possible and exhibit promising charge carrier mobilities. Furthermore, printed, monolithically integrated all-polymeric CMOS circuits with good performance will be disclosed.

8831-122, Session 5

High performance field-effect transistors based on 2,6-diphenylanthracene (DPA) with thin film mobility up to 14 cm2V-1s-1 *(Invited Paper)*

Wenping Hu, Institute of Chemistry (China)

An anthracene derivative, 2,6-diphenyl anthracene (DPA), was successfully synthesized with three simple steps and high yield. The compound exhibited high thermal (up to 300 oC without decomposition) and environmental stability (HOMO = 5.6 eV). More attractively, field-effect transistors based on DPA films exhibited remarkable high performance, with mobility as high as 14.3 cm2V-1s-1, current on/off ratio >107 (up to 109) as well as long term stability. The high performance is assigned to the dense molecular packing of DPA and the high crystallinity of its films. The facile and high yield synthesis, high stability, and remarkable transistor performance in films, indicate the great potential of DPA for applications in organic electronics.

8831-123, Session 5

High performance liquid crystalline organic field effect transistor materials: How does the liquid crystallinity solve problems in conventional soluble OFET materials? *(Invited Paper)*

Hiroaki Iino, Takayuki Usui, Jun-ichi Hanna, Tokyo Institute of Technology (Japan)

No Abstract Available

8831-124, Session 5

Electronics by printing *(Invited Paper)*

Jie Zhang, A*STAR Institute of Materials Research and Engineering (Singapore)

It has been the mission for organic based functional materials development society that using low cost graphic arts printing technology to process functional devices for integrated circuits, solar cells, and light emitting devices. The reality is what device can be printed and how the printed devices performance. In this study, the team of scientists and engineers developed material systems, interface and process technologies that are able to print transistors, using graphic art printing technologies, with field mobility range from 0.8 to 2.4 cm2/V.s at the OFET channel length of 100 um. The subsequent logic and analog circuit are designed and fabricated based on the printed transistors. The circuit performances are evaluated. The design rule of the printed circuits, using graphic arts printing, is discussed.

8831-125, Session 5

Heteroannulenes: novel materials for organic field-effect transistors

Tarunpreet Singh Virk, Kamaljit Singh, Guru Nanak Dev Univ. (India)

In the course of development of cyclic conjugated chemical entities, structural variations of the fundamental tetrapyrrolic porphyrinoids by way of replacing pyrrole with other heterocyclic species and/or changing the topology of the macrocyclic framework in a manner that p-electron conjugation pathway is maintained, has led to the synthesis of potentially rich families of neutral as well as charged heteroannulenes. We have disclosed the electronic structure and demonstrated the use of meso-aryl tetraoxa[22]annulene[2,1,2,1] (1) and tetrathia[22]annulene[2,1,2,1] (2) as thin film organic field-effect transistors (OFETs). These molecules showed moderate to high on/off ratio along with a high reproducible bulk-like carrier hole mobility. The tetrathia annulenes also showed weak interaction with the electron accepting TCNQ as shown by X-ray crystal structure. Such a molecular level hetrojunction (3), showed air stable ambipolar charge transport behaviour. Further the tailoring of the tetrathia annulenes has been done by appending the electron withdrawing substituents to them which led to improvement of their on/off ratios along with good to high hole mobility, a characteristic required for application in switching (2). The details of designs of macrocyclic entities, structure, physical properties, charge mobility characteristics as well as chemosensing behavior shall be presented.

Exploration of new building units for high-performance semiconducting polymers *(Invited Paper)*

Itaru Osaka, RIKEN (Japan)

Exploration of new building units is crucial for the development of high-performance semiconducting polymers. Since semiconducting polymers for p-channel transistors are required to have deep HOMO level as well as high crystalline structures, key building units are relatively “weak” donor (electron-rich) and relatively “strong” acceptor (electron-poor) units that ensure strong intermolecular interactions. In this presentation, we show the synthesis, characterization, properties, thin film structures, and transistor performances of semiconducting polymers based on several new building units, namely, napthodithiophene (NDT) as the donor, and naphthobisthiadiazole (NTz) and thienothiophenedione (TTD) as the acceptor. The polymers exhibited quite high charge carrier mobilites of 0.5–1.4 cm2/Vs. The correlations between the polymer structure, electronic structure, crystallinity, and charge transport properties will be discussed.

Development of a new polymeric semiconductor material: characterization, performance, and application *(Invited Paper)*

Mingqian He, James R. Matthews, Robert A. Bellman, Kristi L. Simonton, Weijun Niu, Arthur L. Wallace, Jieyu Hu, David N. Schissel, Michael J. Winningham, John C. Mauro, Corning Incorporated (United States); Hon Hang Fong, Shanghai Jiao Tong Univ. (China); Wen-ya Lee, Zhenan Bao, Stanford Univ. (United States)

A new fused-thiophene diketopyrrolopyrrole based semi-conducting polymer has been designed and synthesized. Many synthetic challenges were overcome in the development of a practical scalable synthesis of this new material. Characterization by GPC over a range of temperatures has revealed the tendency of this polymer to aggregate even at elevated temperatures and confirmed that the final values obtained for molecular weight are for non-aggregated material. The ability to obtain accurate molecular weight information makes it possible to study the relationship between mobility and molecular weight. This polymer shows great solubility in many different hydrocarbon solvents, while also giving excellent device performance with very high mobilities when deposited from those solvents. The polymer has also been studied on different substrate materials, including those not amenable to traditional electronics, to explore potential new applications.

Engineering charge transport in organic and nanocrystal semiconductor thin films for flexible electronics *(Invited Paper)*

Cherie Kagan, Univ. of Pennsylvania (United States)

Organic and inorganic nanocrystals are being aggressively pursued as semiconducting materials in low-cost, large-area, flexible electronics. These materials classes are solution-processable enabling their deposition by coating, printing and assembly methods that facilitate their integration in devices and on large-area, flexible plastics. We report chemical routes to engineer materials and device interfaces to manipulate carrier type and mobility to realize high-performance, unipolar p-type and n-type and ambipolar behavior in organic semiconductors and semiconducting nanocrystals for field-effect transistors (FETs). We have integrated FETs as building blocks to realize high gain single organic semiconductor circuits and demonstrated the first nanocrystal integrated circuits.

8831-129, Session 6

New thiophene-diketopyrrolopyrrole based acceptor-donor-acceptor conjugated materials for high performance field effect transistors

Chien Lu, National Taiwan Univ. (Taiwan)

We report the synthesis, morphology, and field effect transistor (FET) characteristics of new acceptor-donor-acceptor conjugated materials, consisted of diketopyrrolopyrrole (DPP) acceptor and four different donors , dithiophene (2T), thieno[3,2-b]-thiophene (TT), dithieno[3,2-b:2',3'-d]-thiophene (DTT), and 5,5'''-di-(2-ethylhexyl)[2,3';5',2'';4'',2''']quaterthiophene (4T). The optical band gaps (eV) of the prepared materials are lower than 1.7 eV, attributed by strong donor/acceptor intramolecular charge transfer and the backbone coplanarity of the thiophene moieties. The order of the crystallinity is TT2DPP > 4T2DPP?2T2DPP > DTT2DPP, resulted from the cis/trans-stereo-structure. TT2DPP and 2T2DPP belong to the trans-stereo structure but DTT2DPP with the cis-stereo structure, which probably leads to different crystallinity. On the other hand, 4T2DPP with the biaxial structure exhibits different lamellar diffractions compared to 2T2DPP. The conjugated materials show well-interconnected small nanorods. The FET devices after thermal annealing exhibit the hole mobility of 3.73?10-2 , 8.38?10-2, 1.62?10-2, and 6.02?10-2 cm2V-1s-1 for 2T2DPP, TT2DPP, DTT2DPP, and 4T2DPP, respectively, which is consistent with the order of the crystallinity. In addition, the FET?hole mobility of TT2DPP is improved to 0.1 cm2V-1 s-1?through solution-shearing. The experimental results suggest the potentials applications of the new DPP-thiophene-DPP conjugated materials for organic electronic devices.?

Tuning rubrene crystal structures via polymer binders and its applications in organic field effect transistors

Pil Sung Jo, Duc T. Duong, Joonsuk Park, Robert Sinclair, Alberto Salleo, Stanford Univ. (United States)

Solution processable organic semiconductors are very promising materials because of their potential applications such as RFID tags and electronic paper. Among organic semiconductors, 5,6,11,12-tetraphenylnaphthacene (rubrene) has very high field effect mobilities (~20 cm2 V-1 s-1) in the form of single crystal fabricated by vacuum methods. However, only a few solution methods for fabricating rubrene devices have been reported. Among the reports, devices based on a blend of rubrene with polystyrene polymer and glass forming diluents exhibit moderate mobilities (>0.1 cm2 V-1 s-1) considering that the devices are thin films. To my knowledge, however, there have been no attempt to understand the effects of the type of the polymer on rubrene crystallization and the resulting device performance.

Here, we investigate polymer binder effects on phase separation, crystallization, and resulting electrical properties of rubrene in organic field effect transistors. Rubrene was blended with three different amorphous polymers: polystyrene (PS), poly(methyl methacrylate) (PMMA), and poly(4-vinylpyridine) (P4VP). The blends were spin-cast and then thermal annealed to induce crystallization. Depending on the polymer binder, different crystal structures of rubrene were observed with X-ray and electron diffraction techniques. To measure the electrical properties of the rubrene / polymer, bottom-gate and top-contact field-effect transistors were fabricated. Among the three blends, devices based on rubrene / PS have the highest mobilities (?ave = 0.5 cm2 V-1 s-1) while those based on rubrene / PMMA did not result in any working devices. For industrial applications, patterning of rubrene / PS was also demonstrated by spin-coating on chemically patterned substrates.

Chain conformations dictate multiscale charge transport phenomena in disordered semiconducting polymers *(Invited Paper)*

Andrew J. Spakowitz, Stanford Univ. (United States)

Semiconducting polymers play an important role in a wide range of optical and electronic material applications. It is widely accepted that the polymer ordering impacts charge transport in such devices. However, the connection between molecular ordering and device performance is difficult to predict due to the current need for a mathematical theory of the physics that dictates charge transport in semiconducting polymers. Here, we present a new analytical and computational description in which the morphology of individual polymer chains is dictated by well-known statistical models and the electronic coupling between units is determined using Marcus theory. This effort combines our research group's modeling efforts in polymer conformational properties and reaction-diffusion phenomena to address the multiscale dynamics of charge transport in a heterogeneous material. The resulting model is capable of bridging molecular-level charge transport mechanisms to large scale transport behavior, thus facilitating direct comparison with experiments. The multiscale transport of charges in these materials (high mobility at short length scales, low mobility at long length scales) is naturally described with our framework. Additionally, the dependence of mobility with electric field and temperature is explained in terms of conformational variability and spatial correlation. Our model offers a predictive approach to connecting processing conditions with transport behavior.

8831-132, Session 7

Using synchrotron x-ray scattering to discover the molecular packing in high performance organic semiconductor thin films *(Invited Paper)*

Stefan C. Mannsfeld, SLAC National Accelerator Lab. (United States)

In polycrystalline thin films of small organic semiconductor molecules, the precise molecular packing determines the film's intrinsic charge transport properties and consequently the electrical performance in thin-film devices such as organic thin film transistors (OTFTs). Synchrotron X-ray scattering is a powerful method to extract molecular packing details in such films that cannot currently be obtained by any other available technique. It can, in fact, be used to analyze films as thin as a fraction of a single monolayer. We employ a combination of Grazing Incidence X-ray Scattering (GIXS) and advanced crystallographic refinement calculations to obtain a detailed picture of the molecular packing at the emiconductor/dielectric interface in OTFT thin films.

The capability to obtain the detailed molecular packing with this approach is highlighted at the example of several organic semiconductor thin film systems, including high performance solution-deposited materials, both n-type and p-type, that exhibit field effect mobilities > 3 cm^2/Vs in the respective OTFT devices. In vacuum-deposited monolayer films of alkylated short oligoacenes on silanized SiO2 surfaces, our approach reveals a marked odd-even effect in the molecular packing. Finally, we discuss the implementation of in-situ printing of OTFT thin films directly at the beam line as a tool that allows us to study the crystallization kinetics and morphology formation during the drying of the ink.

8831-133, Session 7

On the phase behaviour of organic semiconductors and its influence on organic transistor performance *(Invited Paper)*

Natalie Stingelin-Stutzmann, Imperial College London (United Kingdom)

The physical organisation, from the molecular to the macro-scale, of functional organic matter such as polymer semiconductors can profoundly affect the properties and features of the resulting architectures and their consequent performance when used as active layers in organic optoelectronic devices, including organic thin-film field-effect transistors, organic light-emitting diodes or organic photovoltaic cells. Here, we present a survey on the principles of structure development from the liquid phase of this interesting and broad class of materials with focus on how to manipulate their phase transformations and solid-state order to tailor and manipulate the final 'morphology' towards technological and practical applications. We will discuss blending, nucleation and use of processing aids to control the microstructure targeted for field-effect transistor applications.

8831-134, Session 7

New insights into solution processing of organic semiconductors *(Invited Paper)*

Aram Amassian, King Abdullah Univ. of Science and Technology (Saudi Arabia)

As solution processing of high performance organic thin film transistors (OTFTs) emerges as a viable alternative to vacuum deposition, there is increasing urgency to develop robust and reproducible manufacturing processes compatible with large area substrates. This requires a fundamental understanding of the underlying mechanisms of solution processes including solution-to-solid phase transformation as the solution dries. This talk will present our latest investigation of OTFTs based on small molecules and blends (small-molecule & polymer) prepared using commonly-used lab-based solution processing methods, namely drop-casting, spin-coating and blade-coating. We will explore commonalities and describe key differences in the initiation and mechanisms of thin film formation, leading to significant differences in microstructure and phase separation, as well as dramatic implications on carrier transport in both top- and bottom-contact device scenarios.

8831-135, Session 8

High performance organic electrochemical transistors *(Invited Paper)*

Jonathan Rivnay, George G. Malliaras, Ecole Nationale Supérieure des Mines de Saint-Étienne (France)

Large amplification and fast response are essential for transistors in applications ranging from switching elements to measurement of fast biological events such as neuronal action potentials. To this end, organic electrochemical transistors (OECTs) based on conducting polymers such as PEDOT:PSS {poly(3,4-ethylenedioxythiophene) doped with poly(styrenesulfonate)} have been recently targeted for applications in environmental and biological sensing due to their efficient ionic to electronic signal transduction in aqueous. OECT operation relies on the modulation of drain current by the de-doping of PEDOT upon application of a gate bias (which causes a drift of cations into the bulk of the channel). Such operation is notably different other electrolyte-gated TFTs which largely rely on interfacial ion accumulation to enhance the field effect. Efficient OECT operation requires fast electronic pathways for holes, and hydrated phases for mobile ion drift. However, relatively little is known of the solid state and hydrated structure of PEDOT:PSS relevant for electronic and ionic transport. Through active material structure-property investigations as well as micron-scale fabrication and optimization we present a solution processed organic electrochemical transistor with a transconductance approaching 4 mS, and a broad/invariant frequency response from steady state to 5-10 kHz. With proper device design, PEDOT-based OECTs can be made to completely shut off: exhibiting 10mV/decade sub-threshold slopes and on:off current ratios exceeding 10^4. The relative ease of fabrication and ability to embed active devices in thin polymeric substrates allows for extreme flexibility, maintaining high performance after aggressive crumpling. Along with stable operation in vivo and in cell culture, such characteristics make OECTs ideal candidates for low signal, transient biological recordings.

8831-136, Session 8

Tuning polarity and improving charge transport in organic semiconductors *(Invited Paper)*

Joon Hak Oh, A-Reum Han, Hojeong Yu, Eun Kwang Lee, Moon Jeong Jang, Ulsan National Institute of Science and Technology (Korea, Republic of)

Tuning dominant polarity of charge carriers and improving their mobilities are of great importance for realizing on-demand, target-specific, high-performance organic circuitry. The ability to selectively tune the dominant polarity of organic semiconductors enables a range of practical applications such as tailor-made p-n junctions and complementary metal oxide semiconductor (CMOS)-type organic logic circuits which offer various advantages including sophisticated control of current-voltage characteristics, lower power dissipation, greater operation speed, and higher stability. In addition, chemical or biological sensors based on polarity-tunable organic semiconductors can obtain the benefit from the selective manipulation of the electrical signals transduced by the analyte binding events. In particular, ambipolar polymer semiconductors provide a number of advantages for the cost-effective production of CMOS-type circuits as they can be deposited in the simplest single processing step, while maintaining the attractiveness of easy solution processing. Herein we report viable approaches to selectively tune the dominant polarity of charge carriers in solution-processed ambipolar organic field-effect transistors (OFETs). In addition, we introduce our molecular design strategies for achieving efficient charge transport in organic semiconductors, which embraces the rational design of conjugated backbones, the side-chain dynamics, and the crystallinity control of the active layer.

Printing technique dependent charge carrier velocity distribution in organic thin film transistors

Simone Ganz, Sebastian Pankalla, Manfred Glesner, Edgar Dörsam, Technische Univ. Darmstadt (Germany)

Charge carrier velocity distribution was investigated in printed organic thin film transistors. We found a direct dependency of the velocity distribution on the surface morphology of the semiconductor, which reflects the interface between the semiconductor and the dielectric and thus the actual transistor accumulation channel. The effects of flexographic and gravure printing compared to spin coating have been investigated. The surface morphologies differ in waviness and surface roughness due to the respectively used deposition process. The surface was not only varied in the deposition technique itself, but also by changing of cell volume, solid content of the semiconductor formulation and number of printed dielectric layers. The investigated transistors were built in top gate bottom contact architecture. Therefore we replaced the spin coating processes for the organic semiconductor and the dielectric step by step by printing processes to cross-match the investigated layers. Several identical transistors of each kind of process combination were investigated and a compared. The velocity distribution broadens towards slower charges for printed semiconductor layers. Compared to the spin coated ones, printed semiconductor layers show an increased waviness of the surface resulting in an increased interface between the semiconductor and the dielectric on the one hand, and an increased disorder of the semiconductor on the other. In contrast to that we found out that the deposition technique of the dielectric does not seem to influence the charge carrier velocities in the same way.

Lateral solidification of a liquid crystalline semiconductor film induced by temperature gradient

Tomoya Hoshino, Hayato Ito, Ichiro Fujieda, Tomonori Hanasaki, Ritsumeikan Univ. (Japan)

Derivatives of [1]benzothieno[3,2-b]benzothiophene (BTBT) are attracting much attention as a highly soluble, high-mobility semiconductor material for thin-film transistor applications. These small molecules are known to organize themselves into a single crystalline structure after spin coating or drop casting. Charge transport in a single crystal material is anisotropic in nature. Hence, it is desired to control its orientation during growth or recrystallization so that the source and drain electrodes of a transistor are to be placed along a faster transport direction. We propose to generate temperature gradient in a heated liquid crystalline thin film to induce lateral recrystallization. In experiment, we tried two methods. First, an aluminum plate with two narrow ridges was inserted between a temperature-controlled stage and a square silicon substrate with a 200nm-thick SiO2 and a spin-coated C8-BTBT film. We raised the temperature of the stage to 120 C and let it cool gradually. During cooling at around 105 C, the color of the sample started to change, indicating a phase change. This change proceeded from the four corners of the film and in about 30 seconds, the darker regions merged at the center of the substrate. Second, the same sample was placed at the edge of the stage. In this case, the color change started from the protruding corner of the sample and proceeded toward the other end. Micrograph observation revealed that cracks were formed in these films and they were perpendicular to the direction of the phase change.

Screen printing and mechanical polishing of silver contacts for the organic transistor array

Boyu Peng, Jiawei Lin, Paddy K. L. Chan, The Univ. of Hong Kong (Hong Kong, China)

Organic transistor device is a high potential candidate for information storage and sensing applications. Low fabrication cost makes it possible for large area and mass production. Due to the requirement of vacuum deposition or intrinsic limitation of materials, it is difficult to use methods like thermal evaporation or sputtering to achieve large area production in short period of time. In this work, we fabricated large area transistor array based on screen printing and other solution processing methods. With the high resolution printing mesh, we are able to form a 50 ?m transistor channel. Without thermal annealing, the printed silver contacts show resistivity below 10E-4 ?•cm. We also further investigated the reduction of the printed silver thickness and surface roughness by applying mechanical polishing to screen printed Ag gate electrode. We can significantly reduce the surface roughness (rms) from ~150nm to ~10nm. As the solvent content in the Ag paste is less than 10%, instead of using bottom source drain contact, we can screen print the top contact source and drain electrodes onto the organic semiconductors directly without sacrificing the contact resistance. The screen printing parameters, detailed device structures and the connection of the devices will also be discussed.

Two-dimensional analytical modeling of non-linear charge injection in bottom-contact organic field-effect transistors

Franziska Hain, Technische Hochschule Mittelhessen (Germany)

The interest in organic field-effect transistors has grown enormously during the last years. However, analytical compact models of organic transistors suitable for circuit design tools are rarely to find and mostly not able to describe the impact of physical/chemical effects on the electrical device performance sufficiently.

In dependence of different source and drain materials, varying workfunctions, HOMO, LUMO and trap levels the parasitic contact resistance effects became a major problem in organic transistors. So the source semiconductor junction was considered to be the limiting factor for the current flow.

Instead of simply applying well-known compact models of silicon MOSFETs, in our modeling work we followed a fundamental physics-based approach, taking into account the special mechanisms of current transport in organic transistors.

We assumed metallic source and drain electrodes and a random hopping system with localized states e.g. a conjugated polymer as semiconductor.

As the main charge transport mechanisms at the source semiconductor contact we assumed tunneling and drift diffusion processes. The two-dimensional shape of the barrier has been analytically calculated by solving the Poisson equation via the conformal mapping technique.

Following the multiple trapping and release model we assumed that in the channel area the charge transport is only limited by grain boundaries and traps located close to them. In our model we consider these traps with discrete levels at the grain boundaries.

The model results are in good agreement with measurement results published by third parties.

First test structures were printed and are yet to be multiplied.

8831-143, Session PWed

Aging effects on an organic fully printed complementary voltage controlled oscillator

Mathieu Guerin, Emmanuel Bergeret, Evangeline Bènevent, Philippe Pannier, Institut Materiaux Nanoelectronique de Provence (France); Anis Daami, Romain Coppard, Commissariat à l'Énergie Atomique (France)

We present in this abstract an organic fully printed complementary voltage controlled oscillator (VCO). This VCO is completely manufactured by means of mass printing techniques on flexible substrates and consists of a chain of seven looped CMOS inverters. The VCO oscillates at a frequency of 203 Hz with a voltage supply value of +/-20V.

The modelling of devices composing the circuit was made using a-Si TFT model model, then simulations and layout of the circuit were carried out with the Cadence virtuoso suite.

The fabrication process used screen-printing operations for depositing the organic semi-conductor and dielectric materials on a PEN sheet. The whole manufacturing process is made in ambient air.

Since circuits lifetime is one of the most important issues in organic electronics, a study has been performed during one year in order to follow the effects of aging on the circuit performances. The VCO's oscillations were measured right after manufacturing and one year after. The oscillations showed an increase in frequency from 203 Hz to 250 Hz in one year.

In order to explain this behaviour, DC measurements were performed on single transistors made on the same plastic sheet. The measurements made on these one-year-aged transistors showed a decrease of the voltage threshold (Vt) value. This Vt shift explains the frequency change according to the VCO's frequency equation.

The robustness of the presented voltage controlled oscillator is demonstrated since the circuit still oscillates one year after fabrication. The frequency increase is easily explained by the transistors threshold voltage decrease.

8831-144, Session PWed

Coplanar-gate transparent graphene transistors and inverters on plastic

Beom Joon Kim, Seoung-Ki Lee, Sukjae Jang, Sungkyunkwan Univ. (Korea, Republic of); Moon Sung Kang, Soongsil Univ. (Korea, Republic of); Jong-Hyun Ahn, Jeong Ho Cho, Sungkyunkwan Univ. (Korea, Republic of)

Transparent flexible graphene transistors and inverters in a coplanar-gate configuration were presented for the first time using only two materials: graphene and an ion gel gate dielectric.

The novel device configuration simplifies device fabrication such that only two printing steps were required to fabricate transistors and inverters. The devices exhibited excellent device performances including low-voltage operation with a high transistor-on current and mobility, excellent mechanical flexibility, environmental stability, and a reasonable inverting behavior upon connecting the two transistors.

8831-145, Session PWed

Stretchable organic thin-film transistors using inkjet printing method

Soon-Won Jung, Bock Soon Na, Chan Woo Park, Sang Chul Lim, Ji-Young Oh, Jae Bon Koo, Electronics and Telecommunications Research Institute (Korea, Republic of)

Stretchable electronic devices are advanced electronic devices which may maintain electrical functions, even in the case that substrates are expanded or contracted when external stress is applied thereto. A technique for stretchable electronic circuits, differing from typical flexible devices only having a bendable function, has applicability in various fields, such as sensor skin for robots, wearable communication devices, implantable or wearable bio-devices, or advanced displays. A technique of securing stretchability of a device by forming wrinkles on a substrate having circuits formed thereon, a technique of using a stretchable conductive organic material having conductivity instead of metal interconnections, or a technique of patterning metal interconnections in the form of stretchable two-dimensional planar spring may be required in order to realize stretchable electronic devices. In this study, we have demonstrated that top-gated stretchable thin film transistors can be fabricated onto polydimethylsiloxane (PDMS) substrates. Source and drain electrodes were embedded in an elastomer substrates.

8831-146, Session PWed

Effect of dielectric/organic interface properties on charge transport in organic thin film transistors

Ronak Rahimi, Dimitris Korakakis, S. Kuchibhatla, West Virginia Univ. (United States)

Charge carrier transport within the organic thin films as well as charge carrier injection between organic layers and organic/inorganic materials such as metal or dielectric layers are crucial factors in determining the efficiency of organic electronic devices. These parameters rely largely on the molecular structure, morphology and ordering of the organic thin films. Therefore, a profound understanding of the structure of organic materials as well as the properties of the interfacial layers is crucial to enhance the performance of the device. To achieve this feat, structure and morphology of PTCDI-C8 and pentacene thin films on Lithium Fluoride (LiF) have been studied using X-ray reflectivity (XRR) and Raman spectroscopy techniques. These films have been integrated into organic thin film transistors (OTFTs) to investigate their transport properties. The structural characterization revealed that the PTCDI-C8 films form an ordered structure on the LiF dielectric layer. Devices with LiF/PTCDI-C8 bilayer exhibit about one order of magnitude higher output current (Ids) at a constant drain-source voltage (Vds) compared to the devices with LiF/pentacene bilayer. The observed differences in the electrical characteristics of these devices can be attributed to the effects of the dielectric/organic interface and the molecular structure of the organic layers. The results of this study present the importance of the dielectric/organic interfaces in the performance of OTFTs.

8831-147, Session PWed

Optimization of aerosol jet printing for high resolution, high aspect ratio silver lines

Ankit Mahajan, C. Daniel Frisbie, Lorraine Francis, Univ. of Minnesota, Twin Cities (United States)

Aerosol Jet Printing is a recent direct write method that produces feature sizes smaller than the traditional inkjet and screen printing processes. In this technique, the ink is converted to a fine aerosol, and this aerosol mist is directed to a deposition head in a flowing carrier gas. Inside the deposition head, an annular sheath gas focuses the mist to produce a high density deposit with feature size only a fraction of the nozzle. In this paper, the influence of the process parameters on the geometry of aerosol-jet printed silver lines is explored. We demonstrate that the concept of focusing ratio, the ratio of the sheath gas flow rate to the carrier gas flow rate, is central to controlling line features and resistances. Line width decreases upon increasing the focusing ratio; but the thickness increases simultaneously. Both line width and thickness decrease with increasing stage speed. Geometry control also controls the resistance per unit length of the printed lines. The results are condensed into an operability window and region for printing tall and narrow lines in a single pass is identified. Lines as narrow as 20 µm and aspect ratio (thickness/ width) greater than 0.1 are obtained under optimized conditions.

8831-148, Session PWed

Organic memory transistor based on hybrid dielectric

Xiaochen Ren, The Univ. of Hong Kong (Hong Kong, China)

Organic memory devices are known as promising devices for next generation date storage applications due to their flexibility and low fabrication cost. For the transistor based memory devices, by using the hybrid dielectric containing polymer electrets layer, the threshold voltage of memory transistor can be well controlled at the same time having good data retention property and short programming time. However, the physics of traps state in polymer electrets are not well understood and the relative large programming voltage of polymer electrets limits the application of this type of memory devices. We have fabricated the hybrid transistor memory device based on SiO_2 and polystyrene (PS) hybrid dielectric. The trap states density as a function of polymer thickness and molecular weight of PS has been investigated and a maximum 100V memory window between programming and erasing is realized. Furthermore, in order to meet the requirement of portable electronic devices, the capacitance of dielectric material for memory transistor must be higher to reduce the operating voltage. Owing to the high permittivity of Al_2O_3, we fabricated the organic memory transistor based on anodized Al_2O_3/self-assembly monolayer (SAM)/PS hybrid dielectric, the effective capacitance of hybrid dielectric is 210 nF/cm2 and the transistor can reach saturation state at negative 4V gate bias. Spun coated PS on SAM treated surface can form thinner layer compared to the one on untreated Al_2O_3 surface therefore the hybrid dielectric can maintain high capacitance. The memory window in transfer curve is around 1V under +/-5V programming and erasing bias. We will also discuss the potentially applications in large area electrical skin.

Probing the absorption and release of nitroaromatic vapours from carbazole-based fluorescent dendrimer films *(Invited Paper)*

Paul L. Burn, Paul Shaw, Paul Meredith, The Univ. of Queensland (Australia); Michael James, Australian Synchrotron (Australia); Ian R. Gentle, The Univ. of Queensland (Australia)

We present a study into three generations of fluorescent carbazole-based dendrimers that exhibit strong binding with nitroaromatic compounds accompanied by photoluminescence (PL) quenching, making them attractive sensing materials for the detection of explosives such as 2,4,6-trinitrotoluene (TNT). The absorption and release of the (deuterated) TNT analogue, 4-nitrotoluene (pNT), from thin films of the dendrimers were studied with a combination of time-correlated neutron reflectometry and PL spectroscopy. When saturated with pNT the PL of the films was quenched and could only be recovered with a nitrogen gas flow upon heating to 40-80° C. Although the majority of the absorbed pNT was removed by this method the neutron reflectometry showed that the recovered films still contained residual quantities of pNT. However, the proportion of the PL recovered increased strongly with generation with the third generation dendrimer exhibiting full recovery. This result is attributed to a combination of two effects. Firstly, the dendrimer films present a range of binding sites for nitroaromatic molecules, with molecules bound to the higher energy sites remaining after the thermal recovery. Secondly, the exciton diffusion coefficient decreases with dendrimer generation, inhibiting the PL quenching by the bound pNT.

8831-202, Session 1

Design, synthesis, and static charge tuning of organic semiconductors for sensing applications *(Invited Paper)*

Howard E. Katz, Weiguo Huang, Kalpana Besar, Thomas Dawidczyk, Johns Hopkins Univ. (United States)

Organic and polymeric semiconductors are among the alternatives to silicon being considered for sensing devices and circuitry. Their synthesis is now well established, and some performance metrics such as charge carrier mobility and optoelectronic quantum yield exceed those of inorganic counterparts such as amorphous silicon. The best fit for organic semiconductors is in applications where inherent capabilities such as rational modification of carrier energy levels and covalent connection between charge channels and surface receptors are leveraged.
This presentation will describe newly synthesized organic molecular solids and polymer films where these attributes are emphasized. For example, introduction of highly electron donating tetrathiafulvalenes into moderately electron-rich polymers enhances response to electron-poor analytes, and addition of a borane to a semiconductor enhances response to ammonia, for the development of chemical sensors. Carrier energy levels are markedly and predictably altered by static charge embedded in polystyrene films adjacent to organic semiconductors, multiple device activities to be obtained from a single device layout using one semiconductor, and also the avoidance of powering gate electrodes to set the optimal sensitivities during operation. Finally, approaches to optimizing water stability and aqueous-media responses will be discussed.

8831-203, Session 1

Photostable organic fluorescent dots with aggregation-induced emission characteristics for non-invasive long-term cell imaging *(Invited Paper)*

Ben Zhong Tang, Hong Kong Univ. of Science and Technology (China)

Long-term non-invasive cell tracing by fluorescent probes is of great importance to understand genesis, development, invasion and metastasis of cancerous cells. To efficiently trace living cells in a noninvasive and real-time manner, researchers have devoted much effort to develop new fluorescent probes. Traditional π-conjugated fluorophors are prone to aggregate, which often quenches their light emissions and is a common photophysical phenomenon known as aggregation-caused quenching (ACQ). We succeeded in developing a series of efficient organic emitters with aggregation-induced emission (AIE) characteristics with emission colors from green to far-red/near-infrared by linking propeller-like tetraphenylethene (TPE) or silole unit to traditional dyes through covalent bond. Encapsulation of the AIE luminogens in polymer matrix yields optically stable nanoparticles (NPs) with uniform size, high brightness and low cytotoxicity. The AIE NPs carrying specific functional groups show high emission efficiency, large absorptivity, excellent biocompatibility and strong photo-bleaching resistance, making them ideal for targeting specific cells and/or tissues, and long-term non-invasive in vitro and in vivo cell tracing. The organic AIE dots outperform their counterparts of commercial inorganic quantum dots, opening a new avenue in the development of organic fluorescent probes for following biological processes.

8831-204, Session 1

Colorimetric detection of copper in water using a Schiff base derivative

Diecenia Peralta Dominguez, Mario A. Rodriguez Rivera, Gabriel Ramos-Ortiz, Jose-Luis Maldonado-Rivera, Marco Antonio Meneses-Nava, J. Oracio C. Barbosa G, Ctr. de Investigaciones en Óptica, A.C. (Mexico); Rosa Santillan, Ctr. de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional (Mexico); Norberto Farfan, Univ. Nacional Autónoma de México (Mexico)

The synthesis of organic molecules with chemosensors characteristics for detection of heavy metal ions in water is of great importance for environmental applications [1-2]. Organic molecular sensors have the advantage of being used through an easy, fast, economical and reliable optical method for detecting toxic metal ions in our environment. In this work, we present a simple but highly specific organic ligand compound 5-Chloro-2-((E)-((E)-3-(4-(dimethylamino)phenyl)allylidene)amino)phenol (L1) that acts as a colorimetric sensor for ions in a mixture of ACN/H2O (10:1, v:v). Binding interaction between L1 and various metal-ions has been established by UV-Vis spectroscopic measurements that indicate favorable coordination of the ligand with selective metal ions, particularly, with cupper. These results showed that the electronic transition band shape of L1 (receptor compound) change after binding with Cu2+ in aqueous solution. L1 exhibited binding-induced color changes from yellow to pink one detected by the naked eye. This new sensor presented 2.5 ? 10-6 M as limit detection, even under the presence of other metal ions.

8831-205, Session 2

OLED-based sensing of relative humidity and oxygen

Eeshita Manna, Fadzai Fungura, Weipan Cui, Joseph Shinar, Ruth Shinar, Iowa State Univ. (United States)

We compare the use of standard OLEDs to microcavity OLEDs in sensing applications. Green and UV microcavity OLEDs are used for O2 sensing with detection by P3HT:PCBM- or CuPC/C70-based photodetectors in compact all-organic devices. Blended sensing films are developed to enable the monitoring of the effect of relative humidity on the photoluminescence (PL) decay time of oxygen-sensitive dyes in such specific matrices. IR organic photodetectors for monitoring water content/humidity are also presented.

8831-206, Session 2

Integrated sensors for point of care diagnostics *(Invited Paper)*

John C. de Mello, Imperial College London (United Kingdom)

Microfluidic devices have shown themselves to be highly effective for laboratory-based research, where their superior analytical performance has established them as efficient tools for genetic sequencing, proteomics, and drug discovery. However to date they have not been well suited to point-of-care diagnostic applications, where cost and portability are of primary concern. Although the microfluidic chips themselves are cheap and small, they must generally be used in conjunction with bulky optical detectors, which are needed to identify or quantify the analytes or reagents present. Here we report the use of miniature on-chip light sources and photodetectors based on light-emitting polymers, together with a range of new low cost strategies for the sensitive detection of low concentration analytes.

8831-207, Session 2

Organic optoelectronic sensors for security and medical applications *(Invited Paper)*

Ifor D. W. Samuel, Yue Wang, Univ. of St. Andrews (United Kingdom); Alexander L. Kanibolotsky, Peter J. Skabara, Univ. of Strathclyde (United Kingdom); Ashu K. Bansal, Mario E. Giardini, Graham A. Turnbull, Univ. of St. Andrews (United Kingdom)

Organic semiconductors are of considerable interest for a wide range of sensing applications. This talk will present recent advances in two domains of sensing. The first part concerns the use of organic semiconductor lasers for sensing explosive vapour. We have investigated a range of organic semiconductors for this application and compare and contrast their properties. In particular we find that truxenes provide very attractive properties for explosive vapour sensing. The second domain of sensing that we report is a muscle contraction sensor. This device measures changes in muscle optical properties under either isometric or isotonic contraction.

8831-208, Session 2

Fluorescent protein-based photonic devices *(Invited Paper)*

Malte C. Gather, Technische Univ. Dresden (Germany) and Massachusetts General Hospital (United States) and Harvard Medical School (United States)

The discovery and development of fluorescent proteins represents a major breakthrough for biomedical research and has enabled non-destructive monitoring and imaging of various biological processes in-vivo. Based on our recent finding that the green fluorescent protein, GFP, can not only serve as a fluorescent probe but is also capable of generating stimulated emission in an efficient manner, we discuss possibilities to use fluorescent protein-based cell lasers and other protein based devices as sensors. In particular, we will discuss the properties of these proteins in the solid state and demonstrate lasing and sensing applications based on solid state protein devices.

8831-227, Session PWed

Triphenylamine and naphthalimide derivatives for optoelectronic applications

Saulius Jursenas, Arunas Miasojedovas, Vygintas Jankauskas, Vilnius Univ. (Lithuania); Gjergji Sini, Univ. de Cergy-Pontoise (France); Dalius Gudeika, Asta Michaleviciute, Ramunas Lygaitis, Saulius Grigalevicius, Juozas V. Grazulevicius, Kaunas Univ. of Technology (Lithuania)

Organic electroactive molecules having both donor and acceptor substituents are of increasing importance for the application in optoelectronic devices such as bulk heterojunction solar cells and sensors.

1,8-naphthalimide derivatives represent an attractive class of electron-deficient organic materials with high electron affinities. They have wide energy gaps and low reduction potentials. Organic molecules containing triphenylamine units are of significant importance among the solution-processable amorphous organic molecular materials, and have been intensively investigated for the applications in optoelectronic devices. These derivatives show pronounced hole transporting ability.

In this work photophysical properties of a series of novel solution-processable 1,8-naphthalimide derivatives with triphenylamine fragment as core have been investigated. The compounds was found to show ambipolar charge transport with electron mobility values up to 7.5?10^-4 cm2/Vs at an electric field of 1?106 V/cm. The optical and electrical properties of the compounds are rationalized by density functional theory modeling. The impact of polar groups and the number of naphthalimide arms on optical end electrical properties of the compounds is discussed. The compounds show efficient fluorescence (up to 78%) and pronounced positive solvatochromic effect in wide range of 400-730 nm with reasonable fluorescence efficiency. The compounds embedded in a transparent polystyrene matrix as temperature-time fluorescence sensors exhibit reverse color changes upon annealing.

8831-228, Session PWed

Stimuli responsive poly-N-isopropylacrylamide - phenylene vinylene oligomer conjugate

Young Il Park, Bingqi Zhang, Cheng-Yu Kuo, Jennifer S. Martinez, Hsing-Lin Wang, Los Alamos National Lab. (United States)

Phenylene vinylene trimer (OPV) and PNIPAM conjugate with stimuli responsive optical properties has been synthesized through formation of amide linkage between PNIPAM and carboxylic acid terminated OPV. This material exhibits thermoresponsive optical properties as temperature exceeds lower critical solution temperature (LCST), which is 32 oC for PNIPAM and the conjugate. This PNIPAM-trimer conjugate is fully characterized by using NMR, FT-IR, temperature-dependent UV-Vis and fluorescence spectroscopy. We have found the polymer conjugate solution turns opaque as temperature exceeds LCST and a five-fold increase in quantum yield (QY) as temperature increases from 20 oC to 70 oC. Such distinct increase in QY is likely due to the rigidchromism; i.e., change in optical properties due to confinement of the chromophores resulting from restriction of polymer conformational structures. The PNIPAM-trimer conjugate also show decrease in decay life time with increasing temperature, while OPV trimer alone shows no change in decay life time as a function of temperature. These unique optical properties are not observed in trimer and PNIPAM mixture, suggesting the stimuli responsive optical properties can only occur in PNIPAM/trimer conjugate linked through covalent bond.

8831-229, Session PWed

An implantable PVDF microphone for the totally implantable cochlear implant

Andy Zhang, Elizabeth Olson, Ioannis Kymissis, Columbia Univ. (United States)

A cochlear implant (CI) is a semi-implantable prosthesis that partially restores hearing by electrically stimulating the hearing nerves in the inner ear. A major advance for the future would be a totally implantable prosthesis, where all the external components of the current CI device are implanted under the skin. To achieve this, one of the major challenges is to develop an implantable acoustic sensor to replace the external microphone currently used with CIs.

In this paper, we report on the development of a piezoelectric polymer microphone, which is designed to be implanted in the inner ear to pick up the sound pressure in the cochlear fluid. A significant advantage of such a microphone placement is that it includes the outer and middle ears as part of the sound pick-up. The outer and middle ears function normally in most CI recipients, but are totally bypassed in the current CI devices. To study this novel concept, we designed a proof-of-principle prototype, which is based on the micro-fabrication processing of PVDF polymer films. The PVDF film is both the device substrate and the piezoelectric material of the microphone. This poster will demonstrate the scaled prototype and an evaluation of the performance and feasibility of the design concept.

8831-230, Session PWed

Potential application of organic self-assembled monolayers to TiO2-based photodetectors

Chun-Pei Cho, National Chi Nan Univ. (Taiwan)

Monitor of UV radiation is an ongoing research topic to develop UV photodetectors with a device structure very similar to dye sensitized solar cells (DSSC) consisting of nanocrystalline TiO_2. With a wide band gap, TiO_2 is inherently UV selective [1]. It has been demonstrated that porous TiO_2 nanostructures improve photoresponsivity owing to the light scattering effect which enhances light harvesting efficiency [2]. Therefore, the nanoporous TiO_2 electrode utilized in DSSCs can also be applied to fabricate TiO_2 photodetectors. It has been known that the photoresponse of a TiO_2 photodetector largely depends on its energy band gap. Moreover, the responsivity is increased by reducing Schottky barrier at TiO_2 interface [3]. So the concept of tuning energy barriers, which has already been employed in organic electronic devices using self-assembled monolayers, has potential application to TiO_2 photodetectors [4,5]. As the approach we modified the TiO_2 photoelectrodes for DSSCs, phosphonic acids with various terminal groups and chain lengths can be selected to form dipole layers on TiO_2 surface to investigate how the modifications affect the open-circuit voltages (Voc), leakage currents, electron lifetime, charge recombination, response times and external quantum efficiency, etc., of the photodetectors made of nanoporous TiO_2. When a phosphonic acid with a negative dipole moment is used, the conduction band bottom (ECB) of TiO_2 shifts closer to the vacuum level. This could cause a larger Voc, suppression of charge recombination and leakage current, and probably a higher photoresponsivity. It has been demonstrated that Voc is dipole-related, indicating that the performance of a TiO_2 photodetector could be improved if a phosphonic dipole layer appropriately alters the energy band gap of TiO_2 and the Schottky barrier at TiO_2 interface. The I-V curves, photoelectrochemical parameters and electrochemical impedance spectra have been measured for further discussion and explanations.

8831-209, Session 3

Organic field-effect transistors and organic diode structures for ion-detecting sensor elements in aqueous environment *(Invited Paper)*

Emil J. W. List, Technische Univ. Graz (Austria) and NanoTecCenter Weiz Forschungsgesellschaft mbH (Austria)

Organic field-effect transistors (OFETs) are highly promising candidates for chemical and biological sensing. Many organic compounds are solution-processable at low temperatures on a variety of substrates, which allows for cost-effective fabrication methods, leading to smart (disposable) sensor tags in the field of health-, food- and environmental monitoring. Concerning the detection of ions or biological molecules in aqueous solutions, a water-stable operation of OFET sensor elements is crucial. Thus low voltage operation is a prerequisite.

In this context electrolyte-gated OFETs (EGOFETs) seem to be the devices of choice. Due to the formation of an electric double layer at the electrolyte/organic semiconductor interface, they exhibit a very high capacitance allowing for a low voltage operation. Moreover, it was reported that devices are stable even if the organic semiconductor is in direct contact with water. Since these transistors are very sensitive to changes of the interface potential they constitute ideal candidates as transducers for potentiometric ion sensors.

Here the realization of ion-selective EGOFETs is discussed. In this context the device stability of poly(3-hexylthiophene) (P3HT) – based EGOFETs on various substrates gated using water and different concentrations of NaCl in water are presented. In order to obtain a sensitive as well as selective response to sodium a commercial available ion selective membrane was introduced and the corresponding interfaces as well as the limiting factors of this ion sensor concept were investigated. The applicability of the sensor is tested in ambient conditions using a broad variety of analytes with and without interfering ions (e.g. different mineral waters).

This work was supported by the projects “BioOFET 2” and „MIEC-DEVs“ funded by the Amt der Steiermärkischen Landesregierung.

8831-210, Session 3

Electrostatically coupled chemical sensors based on organic semiconductors *(Invited Paper)*

Ananth Dodabalapur, Davianne Duarte, Barrett C. Worley, Bradley J. Holliday, The Univ. of Texas at Austin (United States)

Recently, we proposed and demonstrated sensors based upon the 4-terminal coupled field-effect transistor sensor concept. These sensors employ electrostatically coupled channels: one channel is typically a chemically sensitive organic semiconductor and the second is silicon. This architecture effectively combines the demonstrated chemical sensitivity and selectivity of organic semiconductors (which can be further enhanced through the use of suitable receptors) and the sensitivity and robustness of silicon technology. Such sensors were found to be very sensitive – considerably more so than equivalent three terminal organic field-effect transistor sensors. In this presentation we compare such sensors with a new type of coupled sensor that we have proposed: an electrostatically coupled chemiresistor and field-effect sensor. This new type of sensor is two sensors in one: the chemiresistor sensor (with appropriate receptors) is exposed to the sensing ambient and the capacitively coupled Si transistor channel is sensitive to dipoles induced by analyte molecules interacting with receptors. This large dipole moment can trap charges in the organic chemiresistive layer leading to threshold voltage shifts in the silicon channel. We will also describe a model and experimental procedures we have developed to select suitable receptor molecules.

8831-211, Session 3

Printed, low voltage electrolyte gated transistors and circuits *(Invited Paper)*

C. Daniel Frisbie, Univ. of Minnesota (United States)

By virtue of their enormous gate capacitance, electrolyte gated transistors (EGTs) can operate at supply biases as low as 1 V which makes them interesting devices for application as wearable potentiometric or amperometric biosensors. This talk will review the current performance of p-type and n-type EGTs and discuss their fabrication using printing methods. Specific device metrics that will be covered include ON/OFF current ratio, threshold voltage, carrier mobility, stage delay time, and operational stability. Simple EGT demonstrator circuits and sensing applications will also be discussed.

8831-212, Session 3

Flexible organic active matrix amplifier system for biomedical applications *(Invited Paper)*

Tsuyoshi Sekitani, Tomoyuki Yokota, The Univ. of Tokyo (Japan)

We demonstrate the fabrication of a large-area flexible strain-sensing system consisting of a two-dimensional array of organic self-bias-feedback amplifier cells with signal gain of 400 by integrating 2-V operational organic pseudo-CMOS inverters self-bias amplifier system with polymeric piezoelectric (PVDF) sheet. The amplifier system consists of a self-assembled monolayer (SAM) capacitor matrix sheet, two-dimensional array of organic pseudo-CMOS inverter with floating gate structure sheet and an active matrix of organic field effect transistors sheet. The amplifier sheet comprises 8 ? 8 amplifier cells with an effective size of 7 ? 7 cm2. The organic transistors exhibit mobility of 1.7 cm2/Vs in the saturation regime. When we touch the cell of PVDF sheet (mechanical pressure is applied), the small signal is generated by intermolecular polarization in the PVDF. These signals are amplified by organic amplifier circuits from 10 mV to 150 mV.

A 2D array of organic amplifiers (active matrix amplifier system) was fabricated directly on a 75-?m-thick flexible polyimide substrate. The amplifier was fabricated using an inverter with a pseudo-CMOS layout comprising four p-channel organic transistors. The flexible, p-type channel was formed using dinaphtho[2,3-b:2?,3?-f]thieno[3,2-b]thiophene (DNTT), and gate dielectrics were formed with 4-nm-thick aluminum-oxide and a 2-nm-thick self-assembled monolayer. The manufactured transistor active matrix is encapsulated within a 2-?m-thick parylene by chemical vapor deposition. to serve as a passivation layer and as an overcoat layer for enhancing mechanical flexibility and durability. Proposed organic transistors and circuits exhibited excellent thermal stability and no degradations were observed even after 121 oC for 20 min.

8831-213, Session 3

OECT based devices for monitoring dynamics of bio-relevant molecules and nano-systems towards biomedical applications and drug delivery

Giuseppe Tarabella, Agostino Romeo, Nicola Coppedè, Pasquale D'Angelo, Roberto Mosca, Consiglio Nazionale delle Ricerche (Italy); Roberta Alfieri, Univ. degli Studi di Parma (Italy); Alessandro Pezzella, Marco d'Ischia, Univ. degli Studi di Napoli Federico II (Italy); Pier Giorgio Petronini, Univ. degli Studi di Parma (Italy); Salvatore Iannotta, Consiglio Nazionale delle Ricerche (Italy)

Among the most promising OTFT biosensors devices, Organic Electrochemical Transistors (OECTs) based on conductive polymers have been successfully applied for sensing and monitoring bioelements in liquids environment with high sensitivity. We have recently demonstrated the ability of OECT to be very sensitive to different kind of pharmacophores relevant for nanomedicine and drug delivery area, such liposomal structures and functionalized nanoparticles, with very high sensitivity and real-time capabilities. Normal and cancer cells have been cultivated directly on the OECT channel and the cellular response induced by drugs and other chemical substances has been monitored in real-time. As an interesting e-textile application, we have realized an OECT integrated in a single cotton fiber able to detect saline concentration directly in real sweat, the device being easily integrable with garments. We have recently exploited OECT as a very sensitive device to monitor eumelanin-type biopolymers in colloidal suspension, showing the great versatility of conductive polymer and the first evidence of OECT response to insoluble materials. Here, we propose for the first time OECT as a tool for the analysis of redox properties of phase-responsive eumelanin biopolymers, providing direct proof of solid state quinone-hydroquinone exchange under conditions of relevance for bioorganic electronics.

8831-214, Session 4

Progresses in organic electrochemical transistors *(Invited Paper)*

Fabio Cicoira, Ecole Polytechnique de Montréal (Canada)

Organic electroactive materials have recently been introduced in bioelectronics, where electronic signals are translated into ionic bio signals. An example of organic bioelectronic device is the organic electrochemical transistor (OECT). OECTs are used as sensors for glucose, dopamine, cells and bacteria as well as tools to investigate electronic/ionic transport in conducting polymers. OECTs consist of an organic channel (a thin film of a conducting polymer) in ionic contact with a gate electrode via an electrolyte solution. Typically, a positive potential is applied at the gate electrode, which causes cations from the electrolyte to enter the conducting polymer film and dedope it, causing a switching from an oxidized to a reduced state, which results in a decrease of the transistor current. Although OECTs are increasingly used as bioelectronics devices, their operating mechanism is largely unknown, which limits their use in bioelectronics.

Most OECTs are based on the conducting polymer poly 3,4 ethylenedioxithiophene doped with polystyrenesulfonate (PEDOT:PSS), a hole conducting polymer. In PEDOT:PSS the dopant anions (PSS-) are essentially immobile, since they are part of a polymer chain. Therefore the OECT current modulation is controlled mainly by incorporation of electrolyte cations. To study the effect of the different dopant ions, we used PEDOT with non polymeric dopants, obtained by in situ electrochemical polymerization of EDOT in presence of PF6-, BF4-, ClO4-. In PEDOT doped with non polymeric dopants the ions can be released during dedoping, therefore the dedoping process depends on both cation incorporation and anion release. Electrochemical anodic polymerization of 3,4-ethylenedioxythiophene (EDOT) containing different dopant anions was carried out in presence of a supporting electrolyte containing the dopant (e.g. tetrabutylammonium hexafluorophosphate, tetrabutylammonium perchlorate etc.). To study the effect of the electrolyte ions, various cationic surfactants, with different critical micelle concentration and chemical structure, have been used.

8831-215, Session 4

A transparent organic cell stimulator and sensing transistor for bidirectional communication with primary neurons *(Invited Paper)*

Valentina Benfenati, Stefano Toffanin, Simone Bonetti, Istituto per lo Studio dei Materiali Nanostrutturati (Italy); Assunta Pistone, Istituto per la Sintesi Organica e la Fotoreattività (Italy); Guido Turatti, E.T.C. S.r.L (Italy); Michela Chiappalone, Istituto Italiano di Tecnologia (Italy); Anna Sagnella, Istituto per la Sintesi Organica e la Fotoreattività (Italy); Andrea Stefani, E.T.C. S.r.L (Italy); Davide Saguatti, Giampiero Ruani, Istituto per lo Studio dei Materiali Nanostrutturati (Italy); Roberto Zamboni, Istituto per la Sintesi Organica e la Fotoreattività (Italy); Michele Muccini, Istituto per lo Studio dei Materiali Nanostrutturati (Italy) and E.T.C. S.r.L. (Italy)

The development of advanced biomedical devices capable of real-time stimulation and recording of neural cells bioelectrical activity is a demand to improve our understanding of the functional mechanisms of the Nervous System and the need for effective in vitro drug screening targeted to neuropathophysiologies.

Organic semiconductor materials which combine long-term biocompatibility and mechanical flexibility are suitable candidates for neural cell interfacing. Here, we report on transparent Organic Cell Stimulating and Sensing Transistors (O-CSTs) that provide bidirectional stimulation and recording of primary neurons. We demonstrate that the device enables depolarization and hyperpolarization of primary neurons membrane potential. The transparency of the device also allows the optical imaging of the modulation of the neuron bioelectrical activity. The O-CST device enable extracellular recording with maximal amplitude-to-noise ratio 16 times better than a micro electrode array (MEA) system on the same neuronal preparation. Our organic cell stimulating and sensing device paves the way to a new generation of devices for stimulation, manipulation and recording of neural cell bioelectrical activity in vitro and in vivo.

8831-216, Session 4

Polymer-based artificial retinal prosthesis *(Invited Paper)*

Maria Rosa Antognazza, Diego Ghezzi, Sebastiano Bellani, Nicola Martino, Istituto Italiano di Tecnologia (Italy); Maurizio Mete, Grazia Pertile, Ospedale Sacro Cuore Don Calabria (Italy); Silvia Bisti, Univ. degli Studi dell'Aquila (Italy); Fabio Benfenati, Guglielmo Lanzani, Istituto Italiano di Tecnologia (Italy)

Interfacing organic electronics with biological substrates offers new possibilities for biotechnology due to the unique properties exhibited by organic conducting polymers. These polymers have been used for cellular interfaces in several fashions, including cellular scaffolds, neural probes, biosensors and actuators for drug release. Recently, an organic photovoltaic blend has been exploited for neuronal stimulation via a photo-excitation process. Here, we document the novel use of a single-component organic film of poly(3-hexylthiophene) to trigger neuronal firing upon illumination. Moreover, we demonstrate that this bio-organic interface restored light sensitivity to irradiance in the daylight range in explants of rat retinas with light-induced photoreceptor degeneration. Our organic photovoltaic device proved to possess remarkable light-sensitivity, with a threshold and saturation of retinal field potentials and retinal ganglion cells firing within the daylight range of irradiance and a light threshold of approximately 3 orders of magnitude below the ocular safety limit for continuous exposure to visible light. In addition to this indispensable feature, the organic photovoltaic interface has many potential advantages over previously proposed devices for in-vivo applications, including biocompatibility, no need of external bias, negligible heat generation, and high spatial and temporal resolution in response to pulsed illumination. These findings broaden the possibility of developing a new generation of fully organic prosthetic devices for sub-retinal implants that exploit the unique properties of the polymer interface and its inherent sensitivity to irradiances compatible with physiological levels of illumination. Possibility of subretinal implantation of organic-based artificial prosthesis will be finally presented and critically evaluated.

8831-217, Session 4

H+ and OH-: complementary proton wires in biological proton semiconductors *(Invited Paper)*

Marco Rolandi, Univ. of Washington (United States)

The quest for smaller and faster computing has focused on controlling the flow of electrons and holes in nanoscale molecular structures. In living systems, protonic and ionic currents are the basis for all information processing. As such, artificial devices based on protonic and ionic currents offer an exciting opportunity for bionanoelectronics. Proton transport in nature is important for ATP oxidative phosphorylation, the HVCN1 voltage gated proton channel, light activated proton pumping in bacteriorhodopsin, and the proton conducting single water file of the antibiotic gramicidin. In these systems, protons move along hydrogen bond networks formed by water and the hydrated biomolecules (proton wires). Along these wires, protons hop according to the Grotthuss mechanism. Here, I will draw an analogy between the Grotthuss proton transport and electronic semi conductivity. Acids are described as H+ donors and bases are described as H+ acceptors. These functional groups yield H+ and OH- (proton hole) conducting devices in parallel with n-type and p-type electronic semiconductors. Results from H+-OH- junctions and complementary H+-FETs will be discussed in light of this description. In turn, insights from these devices may be used to see proton transport in biological systems from an alternate perspective.

8831-218, Session 4

Biocompatible electro-ionic signal transduction for bioelectronic interfaces *(Invited Paper)*

Paul Meredith, The Univ. of Queensland (Australia); Albertus B. Mostert, Lancaster Univ. (United Kingdom); Graeme R. Hanson, Kristen Tandy, The Univ. of Queensland (Australia)

An essential element of bioelectronics is the interfacing of conventional electrical control circuitry with a biological entity to read or write information. This poses two particular challenges: i) even the most apparently benign inorganic semiconductors such as silicon have biocompatibility issues; and ii) electrical signals in biological systems are dominated by ion and proton flows, chemical potential gradients, etc. whilst semiconductors are intrinsically "electronic", i.e. current flow is via electrons and holes. This latter requirement means that ion-to-electron (or vice versa) transduction is often required across the in-vivo-ex vivo interface [1].

In my talk, I will address these specific issues and discuss materials and architectures which potentially could allow biocompatible electro-ionic transduction. I will review recent progress and challenges in areas such as proton transistors ("protonics") [2], ionic bipolar junction transistors [3] and hybrid ionic-electronic conductors. Furthermore, I will explore the rather exotic solid-state transport physics at play in naturally occurring biomacromolecules that display hybrid electrical behaviour when partially

hydrated. These materials have significant potential for addressing both the biocompatibility and transduction challenges in bioelectronic interfaces [4].

Bio-organic interfaces for cellular photo-excitation

Nicola Martino, Istituto Italiano di Tecnologia (Italy) and Politecnico di Milano (Italy); Maria Rosa Antognazza, Diego Ghezzi, Fabio Benfenati, Istituto Italiano di Tecnologia (Italy); Guglielmo Lanzani, Istituto Italiano di Tecnologia (Italy) and Politecnico di Milano (Italy)

The most common strategies to control electrical activity in living cells are based on electrical or chemical stimulation. However, in recent years, techniques relying on optical stimuli are emerging as promising alternatives with peculiar advantages, particularly for the high degree of temporal and spatial resolution that can be achieved. Here we describe the technique of cell stimulation by polymer photo-excitation (CSP), which takes advantage of the unique optoelectronic properties of the interface between organic semiconducting thin films and an ionic liquid environment. Due to their intrinsic bio-affinity with biological systems, conjugated polymers have been demonstrated as functional substrates for the growth of different types of cellular systems. CSP exploits their ability to generate electrical stimuli following photoexcitation. In particular, we demonstrate that thin films of poly(3-hexylthiophene) (P3HT) are able to elicit electrical activity in different types of cells, from primary neurons to cellular lines. An interesting result is that the stimulation is equally effective with films obtained by blending the donor polymer with an electron acceptor, but also with single component P3HT layers; this allows us to shed light on the actual photoexcitation mechanism, which is based on a capacitive coupling of the active interface with the cellular membrane, as corroborated by further physico-chemical analysis. Other developments of the technique with important consequences for neuroscientific experimentation will also be presented. These results open the way to a new generation of neuronal communication and photo-manipulation tools.

8831-220, Session 5

Infrared photodetectors from all solution-processed inorganic semiconductors *(Invited Paper)*

Jesse R. Manders, Tzung-Han Lai, Jae Woong Lee, Franky So, Univ. of Florida (United States)

Infrared (IR) detection systems are widely used in optical communications, security, ranging, and household electronics. Due to the proliferation of IR-sensitive systems in modern society, high quality photodetectors made from inexpensive and high throughput manufacturing techniques are constantly in demand. Currently, many of the most popular IR photodetectors in use are grown by epitaxial deposition techniques, which are costly and only allow for small area device fabrication. To circumvent the drawbacks of current manufacturing technology, we demonstrate a novel infrared photodetector with tunable absorption spectra by employing all solution-processed inorganic materials. Specifically, quantum dots (QDs) made from lead chalcogenides are used as the IR-absorbing layer, while wide bandgap solution-processed metal oxides are used as the p-type and n-type charge blocking layers in a P-I-N configuration. The absorption spectrum of the IR-active QDs can be tuned throughout a wide swath of the NIR spectrum. Devices have an attractive peak external quantum efficiency (EQE) above 25% and peak responsivity above 0.2 A/W at -1V, comparable to commercially available detectors. Special attention is given to noise levels and frequency-dependent performance of the photodetectors.

8831-221, Session 5

Photoinduced hole-transfer dynamics in organic photodiodes: effects of nanoscale bulk-hetrojunction morphology

Soohwan Sul, Kwang-Hee Lee, Jong-Bong Park, Changhoon Jung, Kyu-Sik Kim, Hyouksoo Han, Samsung Advanced Institute of Technology (Korea, Republic of)

Photo-induced hole transfer dynamics of organic bulk-heterojunction (BHJ) films with different nanoscale morphology is investigated using femtosecond transient absorption (TA) spectroscopy. The BHJ films are composed of N,N'-dimethyl-quinacridone (DMQA) as a donor and a dicyanovinyl terthiophene derivative (DCV3T) as an acceptor, which makes highly efficient green-sensitive organic photodiode (OPD) for image sensor applications. Selective excitations of DCV3T or DMQA/DCV3T in the BHJ films in TA study reveal that charge photogeneration occurs mainly through hole transfer at a donor-acceptor interface and the rate of hole transfer from DCV3T to DMQA depends on the exciton lifetime (1/e-lifetime: ca. 40 ps) and domain size of DCV3T. Hole transfer occurs efficiently with decreasing DCV3T concentration from 75% to 25%, because the domain size decreases and the ratio of interface to bulk increases. On the basis of the charge transfer rate and diffusion length of DCV3T, we estimate the average domain sizes in the BHJ films. For a 50%:50% DMQA:DCV3T blend, the domain size is comparable to DCV3T exciton diffusion length of 5-7 nm. This blend morphology obtained from charge transfer dynamics is compared to the nanoscale morphology obtained from atomic force microscopy and transmission electron microscopy techniques. These results on initial charge transfer rate, recombination, charge photogeneration efficiency, and nanoscale morphology are further discussed in relationship with OPD device performances in terms of charge transport and bias-dependent external quantum efficiency.

8831-222, Session 5

High-gain, low-noise, large linear dynamic range UV hybrid photodetectors enabled by the interfacial trapped charge controlled charge injection *(Invited Paper)*

Jinsong Huang, Fawen Guo, Univ. of Nebraska-Lincoln (United States)

Very weak UV light detection is critically important for defense, air space, radiation sensing applications. Single photon level detection needs UV photodetectors with high gain and low noise. Here, we report a low-cost UV hybrid photodetector which has a huge internal gain of 4,100 under low bias less than 10 volts, enabled by the interfacial trapped charge controlled charge injection. The active materials are organic semiconductors, such as fullerenes, which have strong absorption in UV range. The insertion of buffer layer which composes crosslinked polymer with zinc-oxide nanocrystals simultaneously harvest the high gain as well as the low noise current of the organic photodetector. Strikingly, the noise of the fullerene photodetector with buffer layer was reduced to 7~10 fA Hz-0.5. This low noise was measured directly with lock-in amplifier SR 830, and is approaching the thermal noise limit of 6 fA Hz-

0.5. The combination of low noise and high gain in these photodetectors resulted in a very large specific detectivity of 4?10^15 Jones, which is 2-3 times larger than that of commercial available best silicon and GaN photodetectors in the same spectrum range. Strikingly again, these photodetectors have a super large linear dynamic range in excess of 120 dB under light intensity between 10 fW/cm2~100 mW/cm2, better than any reported solid state photodetectors.

8831-223, Session 5

Integration of transmissible organic electronic devices for sensor application

(Invited Paper)

Furong Zhu, Hoi Lam Tam, Hong Kong Baptist Univ. (Hong Kong, China); Xizu Wang, A*STAR Institute of Materials Research and Engineering (Singapore)

Organic electronics are gradually revealing potential for application in emissive displays, energy generation and optical detection. In this work, we propose a proximity sensor based on the monolithic integration of a semitransparent organic photodetector (OPD), and an organic light-emitting diode (OLED). In the sensor, a thin plasma-polymerized fluorocarbon modified thin silver interlayer is used to connect the front semitransparent OPD and the rear OLED unit. The OPD, possessing strong directional transmission characteristics, acts as an optical coupling layer which enables the enhanced emission from the OLED unit. In addition, it also allows high absorption when light is reflected back from the object. The sensor device has different photo-responses to various types of surfaces, for example, different colored papers and metal foils. Therefore, it can be widely used in the application of planar photo-detectors, imager scanners and proximity sensors.

8831-224, Session 6

Low dark current small molecule organic photodetectors with inverted geometry for hybrid CMOS image sensor applications

(Invited Paper)

Dong-Seok Leem, Kwang-Hee Lee, Kyung-Bae Park, Seon-Jeong Lim, Jung Woo Kim, Yong Wan Jin, Sangyoon Lee, Kyu-Sik Kim, Samsung Advanced Institute of Technology (Korea, Republic of)

Small molecule-based organic photodetectors (OPDs) that are orthogonally photosensitive to different wavelengths of light with R/G/B colors have recently emerged as an alternative to conventional Si-PDs. This enables us to vertically stack the unit R/G/B OPDs in the absence of additional color separation filters, which realise compact, lightweight, and high resolution full color image sensors. In this presentation, we demonstrate high performance green light sensitive OPDs especially with an inverted structure for hybrid CMOS image sensor applications. The inverted geometry i.e., the structure suitable for extracting electrons instead of holes to the bottom electrode of OPDs can provide a good compatibility with conventional CMOS circuits with the characteristic of the electron storage.

Inverted OPDs were fabricated on ITO bottom electrode comprising small molecule organic bulk hetero-junction structures mixed with N,N-dimethylquinacridone (donor) and dicyanovinyl-substituted terthiophene derivative (acceptor), bis-4,6-(3,5-di-3-pyridylphenyl)-2-methylpyrimidine-based charge blocking layer, and a reflective Al top electrode, which exhibited extremely low dark current densities in the range of 1.6-5.4 nA/cm2 at a reverse bias of 3V, high external quantum efficiencies of 55-56% at 540 nm wavelength, and consequently high specific detectivities over 5 ? 10^12 cmHz0.5/W. An additional analysis of 3V-driven OPDs showed the relatively fast photo-response time less than 5 us at cut-off frequency of 70 kHz. Further investigation and characterisation on semi-transparent inverted OPDs by incorporating a thin Ag top electrode will be described in detail for the feasibility of hybrid CMOS imagers.

8831-225, Session 6

Flexible imaging sensors with end application towards x-ray imaging

Abhishek Kumar, Holst Ctr. (Netherlands)

We demonstrate organic imaging sensor arrays on flexible foil fabricated with the solution processing route for both photodiodes and TFTs. We used the photovoltaic P3HT:PCBM blend for fabricating the photodiodes using spin coating and pentacene as semiconductor material for the TFTs. Photodiodes fabricated with P3HT:PCBM are known to have absorption peak in the green light which matches with the typical scintillator output wavelength. The arrays consist of 32x32 pixels with variation in pixel resolution of 200umx200um and of 1mmx1mm. The accurate reproducibility of shadow images of the objects demonstrates excellent potential of these arrays for imaging purpose. We also demonstrate that the crosstalk is insignificant despite the fact that the photodiodes are non-patterned and forms a continuous layer in the array. The semi-transparent top electrode is also a continuous layer above the photodiodes in the array. Further on top we used a thin flexible barrier layer to encapsulate the whole stack to protect from degradation. Since both photodiodes and TFTs are made of organic material, they are processed at low temperatures below 150° C on foil which means that these imaging sensors can be flexible, light weight and low cost when compared to conventional amorphous silicon based imaging sensors on rigid substrates. Further by combining with a scintillator layer on top of the arrays, we show the potential of these arrays for the X-ray imaging application.

8831-226, Session 6

PyzoFlex: a printed piezoelectric pressure sensing foil for human machine interfaces

(Invited Paper)

Martin Zirkl, Gregor Scheipl, Barbara Stadlober, Paul Hartmann, JOANNEUM RESEARCH Forschungsgesellschaft mbH (Austria); Michael Haller, Christian Rendl, Patrick Greindl, Univ. of Applied Sciences Upper Austria (Austria)

Ferroelectric material supports both pyro- and piezoelectric effects that can be used for sensing pressures on large, bended surfaces. We present PyzoFlex®, a pressure-sensing input device that is based on a ferroelectric material. It is constructed with a sandwich structure of four layers that can be printed easily on any material. The foil is bendable, energy-efficient, and it can be produced easily in a printing process (Screen Printing or Roll to Roll). Even a pyroelectric hovering mode is feasible due to its pyro electric effect.

The printed energy autarkic sensors serve as a pressure sensitive user interface enabling for pressure and location sensitive multi touch input. Different routines for elimination of cross talk (iteration, prediction, transport matrix) caused by Kirchhoffs´ law have been exploited and true multi-touch input can be achieved by implementing them into a visualization software of the organic sensor array.

Since ferroelectric sensors are not capable of monitoring static conditions, absolute/static pressure levels can be calculated by knowing the potential function of the sensor systems discharge. By that every upcoming sensor value can be predicted and every deviation from that prediction can be addressed to a predictable change of the static conditions. Finally pressure sensitive gesture detection can be realised by a smart sensor design supported by software interpolation and blob detection. An additional benefit is the possibility of printing a semi-transparent (ITO free) touch interface by using PEDOT electrodes.

The superior sensor performance related to stability, sensitivity, linearity and flexibility is demonstrated.

8832-2, Session 1

A method of comparing the speed of starlight and the speed of light from a terrestrial source

Jing-shown Wu, National Taiwan Univ. (Taiwan); Shenq-Tsong Chang, Instrument Technology Research Ctr. (Taiwan); Hen-Wai Tsao, Yen-Ru Huang, National Taiwan Univ. (Taiwan); San-Liang Lee, National Taiwan Univ. of Science and Technology (Taiwan); Cheng-Chieh Chang, National Taiwan Univ. (Taiwan); Wei-Cheng Lin, Ho-Lin Tsay, Instrument Technology Research Ctr. (Taiwan); Yi-Lung Wang, National Taiwan Univ. (Taiwan); Po-Hsuan Huang, Ming-Ying Hsu, Chia-Wei Hsu, Instrument Technology Research Ctr. (Taiwan); Shu-Chuan Lin, Yung-Jr Hung, Ye-Li Shiu, Yung-Chung Hsiao, National Taiwan Univ. of Science and Technology (Taiwan); Je-Yuan Chang, National Taiwan Univ. (Taiwan); Din Ping Tsai, Ting-Ming Huang, Instrument Technology Research Ctr. (Taiwan); Hong-Tsu Young, Yi-Cheng Liu, National Taiwan Univ. (Taiwan); Chung-Min Chang, National Taiwan Univ. of Science and Technology (Taiwan); Wei-Chieh Chiang, Instrument Technology Research Ctr. (Taiwan); Ji-Ying Huang, Ya-Hsin Chen, National Taiwan Univ. (Taiwan)

The speed of light is an important physical parameter. Currently it is a common belief of the constance of the speed of light regardless of the relative velocity between the source and the observer. Because the speed of light is very fast, if the relative velocity is small compared with the speed of light, it is difficult to detect the effect of the relative velocity on the measurement of the speed of light. In this paper we present a method of comparing the speeds of starlight and the light emitting from a terrestrial source. We use a telescope to collect the light from the star having significant relative velocity with respect to the earth, e.g. Capella. Then we modulate the starlight and the light emitted from the local source into pulses i.e. these pulses leave the modulator simultaneously. After travelling 4.2 km, these pulses are detected by a receiver. If the starlight and the terrestrial light have the same speed, then these pulses must arrive at the receiver at the same time. Our results show that the arrival times of the pulses of starlight are different from that of the local light. For example, the Capella is leaving away from the earth. The Capella pulses arrive later than the local light pulses. It indicates that the speed of Capella starlight is slower than the common believed value, c. The presented method uses one clock and one stick, so the clock synchronization problem and any physical unit transformation can be avoided.

8832-3, Session 1

A quantum oblivious transfer protocol

Abhishek Parakh, Univ. of Nebraska at Omaha (United States)

We propose an all quantum protocol for 1-out-of-2 oblivious transfer. Oblivious transfer is a counter-intuitive cryptographic primitive in which the receiver receives only the information he is authorized for, while the sender does not know what information receiver received. In 1-out-of-2 oblivious transfer, Alice sends two bits to Bob who can choose only one of them to read, while Alice does not know which bit Bob read. The quantum version of oblivious transfer, in the past, unlike the proposed protocol, has only been implemented using a combination of quantum and classical channels. Since it has been shown that it is impossible to build quantum oblivious transfer based on quantum bit commitment protocols, the propose protocol is significant. Further, the protocol is secure if qubits are quanta and cannot be stored, given current technology.

The Protocol: Alice and Bob agree on quantum states |0> and |1> to represent bits 0 and 1, respectively. Further, assume that these states are encoded using photons as qubits. Therefore, Alice encodes the bits she has as qubits X0 and X1. The protocol proceeds as follows:

1) Alice and Bob choose secret random transformations Ua and Ub, respectively, such that they commute, UaUb=UbUa.

2) Alice applies her secret transformation to X1 and X2 and sends Bob Ua(X1) and Ua(X2), in order.

3) Bob chooses the qubit he would like to retrieve, say Xb, and sends to Alice UbUa(Xb)=UaUb(Xb).

4) Alice applies the inverse transformation for Ua on the received qubits and sends to Bob Ub(Xb).

5) Bob applies the inverse transformation on the qubit that he receives and retrieves Xb.

We prove the security of the proposed protocol. Further, we discuss the extension of the above protocol to k-out-of-n oblivious transfer and show some possible attacks on it.

8832-4, Session 1

A high-speed GaAs-based electro-optic modulator for polarization, intensity, and phase modulation

Hiroshi Kato, Optelian (Canada); Jeffrey D. Bull, The Univ. of British Columbia (Canada) and Optelian (Canada); Benjamin Tsou, Optelian (Canada); Nicolas F. Jaeger, The Univ. of British Columbia (Canada)

We report on the development of novel electro-optic modulators fabricated on epitaxial layers of aluminum gallium arsenide (AlGaAs), grown on a GaAs substrate. The current device has a unique single waveguide structure combined with travelling wave slow wave electrodes. This design allows for high speed modulation of the polarization state of light with low differential group delay, low optical loss and frequencies of 50 GHz and beyond. The devices are based on TE-TM mode convertors that modulate the state of light from one linear polarization state to an orthogonal linear state passing through elliptical and circular polarization states. Devices can also be configured to modulate the phase or intensity of an optical signal by appropriate alignment of the polarization axis of the input light or by placing a polarizer at the output. Key characteristics and performance metrics of the devices are reported. Applications that use the device for enhancing analog communication links, analog to digital signal conversion and sending keys for encryption are reviewed to illustrate the diverse nature of the systems being developed and which demonstrate the versatility of the ways in which the GaAs mode converter modulator may be used.

8832-5, Session 1

Numerical examination of acousto-optic Bragg interactions for profiled lightwaves using a transfer function formalism

Monish R. Chatterjee, Fares S. Almehmadi, Univ. of Dayton (United States)

Recent results from an acousto-optic (AO) Bragg cell under first-order intensity feedback, while satisfactory, are limited notionally by the standard AO assumption of uniform plane waves of light and sound. This highly complex wave-particle problem may simultaneously be described via Maxwell's equations, and also a quantum description whereby the upshifted and downshifted orders of diffracted light are represented by a wave-vector triad consisting of two photons and one phonon. Nominally, for uniform plane waves, the Bragg-diffracted first-order light is a sin2 function versus the optical phase-shift parameter

([alpha]0). An earlier model developed for Gaussian profiled plane waves predicted approximately Gaussian scattered beams distorted at higher Q (Klein-Cook) values. We present here profiled optical plane wave propagation through a Bragg cell, examining the scattered first-order beam from different perspectives. The results from non-uniform plane-wave diffraction indicate at least two counter-intuitive outcomes. First, it is found that even for profiled beams, the first-order light maintains its sin2 characteristic analogous to the uniform plane wave case. This unexpected conformity, however, begins to break down at higher Q-values. This is particularly counter-intuitive, since at higher Qs, one would expect the device to behave more Bragg-like than at lower Qs. This may have implications embedded in the properties of photon scattering by phonons, and might well be an area worthy of further explorations. A second observation in the asymptotic limit [alpha]0 --> [infinity] shows an axial shift of the beam profile in the first order, conforming to wave theory predictions; however, the shift appears to exist only on one side of the radial axis and not the other. This finding is also open to explanations based on possible photon scattering by a Bragg cell under profiled beam diffraction.

8832-6, Session 2

Mechanism of photonic interactions

Andrew Meulenberg Jr., Univ. Sains Malaysia (Malaysia) and Hi Pi Consulting (United States)

The normal mathematical model of light, using the simple summation of sine waves, gives excellent predictive capabilities for light. It predicts the results of the interactions for even the components of light, the photons. However, it cannot provide a valid physical model of their interactions or of the photons themselves. This paper attempts to provide such a model that also fits and explains the known characteristics of light and its interactions. The simplest version of this model assumes that there exists, within a photon, 'sources' that produce the observed and mathematically modeled, transverse electric and magnetic fields. These source terms are not physical entities in the normal sense. They represent concentrations of field lines that, in turn, are only gradients of potentials. The nature and consequence of such sources is explored. A main new feature of this model is the recognition of the role of longitudinal field lines. This is a 'what if', rather than a 'how' and 'why', paper.

8832-7, Session 2

A mechanism for wave interaction during interference

W. R. Hudgins, Hi Pi Consulting (United States); Andrew Meulenberg Jr., Univ. Sains Malaysia (Malaysia) and Hi Pi Consulting (United States)

Waves carry energy, force and momentum. Therefore, colliding wave trains have the physical capacity to interact and do so to form and maintain standing waves. Standing waves form in liquids, gases, electrical circuits, and electromagnetic (EM) waves. Because wave behavior exists, irrespective of media type, we have investigated the possibility that waves in various media do interact and do so through a common, physical mechanism. We propose that standing waves are composed of reverberating segments containing reflection zones (nodes) where potential energy resides and where there is little lateral energy flow and kinetic energy zones where lateral energy flow is maximal.

Considering interference phenomena; interference patterns form when waves collide at an angle. During the collision two force vectors resolve. One is the vector sum of the longitudinal components of the two, converging wave trains. The second is the combination of opposing (colliding), transverse acting forces that will produce a standing wave component. This second component separates the longitudinal, moving waves into parallel zones where energy may be only potential in one zone and kinetic in the next. For example, in the interference pattern formed by converging components of a split laser beam (our zero slit experiment, ZSX), potential energy resides in the dark, longitudinal zones (null zones), kinetic energy in the parallel, bright zones. We have experimental evidence that the colliding forces from two converging laser beams produce a standing wave component that can redirect and concentrate the combined, light energy without the use of lenses.

8832-8, Session 2

Does the coherent lidar optical system corroborate non-interaction of waves (NIW) principle of light?

Narasimha S. Prasad, NASA Langley Research Ctr. (United States); Chandrasekhar Roychoudhuri, Univ. of Connecticut (United States)

NIW (non-interaction of waves) has been proposed by one of the coauthors. The NIW principle states that in the absence of any "obstructing" detectors, all the Huygens-Fresnel secondary wave lets will continue to propagate unhindered and without interacting (interfering) with each other. Since a coherent lidar system incorporates complex behaviors of optical components with different polarizations including circular polarization for the transmitted radiation, then the question arises whether the NIW principle accommodate elliptical polarization of light. Elliptical polarization presumes the summation of orthogonally polarized electric field vectors which contradicts the NIW principle. In this paper, we present working of a coherent lidar system using Jones matrix formulation that the system behavior is congruent with NIW principle. The Jones matrix elements represent the anisotropic dipolar properties of the molecules of the optical components. Accordingly, when we use the Jones matrix methodology to analyze the coherent lidar system, we find that this methodology inherently supports the NIW principle.

8832-9, Session 2

Understanding beam alignment in a coherent lidar system

Narasimha S. Prasad, NASA Langley Research Ctr. (United States); Chandrasekhar Roychoudhuri, Univ. of Connecticut (United States)

Optical beam alignment in a coherent lidar or ladar receiver system plays a critical role in optimizing its performance. Optical alignment in a coherent lidar system dictates the wavefront curvature (phase front and Poynting vector) matching of the local oscillator beam with the incoming receiver beam on a detector. However, this alignment is often not easy to achieve and is rarely perfect. Furthermore, optical fibers are being increasingly used in coherent lidar system receivers for transporting radiation to achieve architectural elegance. The detector response characteristics vary with the misalignment of the two pointing vectors. Misalignment can lead to increase in DC current. Also, a lens in front of the detector may exasperate phase front and Poynting vector mismatch. In this paper, we will analyze the extent of misalignment on the detector specifications using pointing vectors of mixing beams. Our analysis will discuss coherent lidar system receiver performance optimization by considering detector characteristics, difference frequency, fringe motion and oscillatory dc current.

8832-10, Session 3

The photon: issues of integrity *(Invited Paper)*

David L. Andrews, Univ. of East Anglia Norwich (United Kingdom)

Since the arrival of the laser, the distinctive and often paradoxical nature of the photon has become more than ever evident. What the optics community now understands by a 'photon' has become much richer – certainly less simple, than Einstein's original conception. There has been a marked expansion in the pace of development since the now familiar

derivative term 'photonics' first emerged, and in much current theory any dividing line between 'real' and 'virtual' photons proves illusory. If, in this technical sense, no photon can ever be regarded as entirely real, one is drawn to the deeper philosophical question of whether the photon is 'real' in the broader sense of reality. Some consider electromagnetic fields to be closest to irreducible reality. Yet whether fields or photons are the terms in which we elect to describe optical phenomena, neither represents what is actually measured. The surest ground is where theory is cast in terms that explain or predict actual observations, under given conditions. It is consistent with the path integral formulation of quantum mechanics that derivations should not prescribe what intervenes between setup and measurement, but instead allow for all possibilities. One of the beauties of the underlying mathematics is its capacity to home in on possibilities that most closely conform to post-event physical interpretation. For practical purposes, a richly diverse range of phenomena now owe their primary conception to the photon; a strong case can be made that in the modern world, 'photonics' has become more real than the photon.

8832-11, Session 3

"Hidden variables" basically unfolded

Erich H. Berloffa, Leopold-Franzens-Univ. Innsbruck (Austria)

Abstract: "Hidden Variables" in QM are entangled with dipole elongation (a) and linewidth (?). It turned out the quantity a?/? plays a dominant role. Rules of QM transition themself are not questioned. This quantity can be fixed for a "single" transition (no interaction with other atoms or molecules) as well as for an ensemble within a thermal bath, and when developed further unveils details of radiating matter especially when the linewidth of the radiating source is precisely known. In principle a "single" isolated local photon emanated by an adequate quantum transition is not detectable.

Stepping towards non-thermal radiation sources (lasers) quantitative assertions can be made in regard of entanglement respectively the lateral dimension affected by such a process. Moreover, this concept applied to g-radiation reveals inherent linewidths of g-ray transitions requires more than a single elementary charge being involved. A further aspect of this investigation makes it obvious: The Stefan-Boltzmann constant is not natural; in fact it is a composition of the constants of Planck and Boltzmann and the velocity of light as well. Exemplary analyzing a specific hydrogen line in the solar spectrum (l= 486 nm) one must infer from its linewidth data this species shows photon entanglement, or alternatively substantial density fluctuations becomes obvious.

Keywords: Single photons, linewidth, entanglement, dipole elongation due to quantum transition, 2D-density of radiating atomic oscillators, solar photosphere.

8832-12, Session 3

Phat photons and phat lasers

Pharis E. Williams, Consultant (United States)

Einstein's initial prediction, based upon statistical considerations, was that the energy of quanta of light be given by h?. A new theoretical development predicts that photon energies are quantized as N2h?. Such quantization of photon energy changes the character of the photon from the Einstein photon that does not have a quantum number. Photon energy that includes a quantum number means that for a given energy the frequency may have more than one value. Conversely, photons of a given frequency may be found that have more energy than the Einstein photon. Further, the phat photons, all at a given frequency will have energy proportional to the number of phat photons and N^2. For these phat photons the electric field strength, which causes breakdown in optical fibers or air, depends linearly on N. Thus, more energy may be transmitted using phat photons of higher quantum numbers than increasing the number of photons of lesser quantum numbers while still keeping the electric field below the breakdown level. Further, while the stimulated and spontaneous emission probabilities are proportional to 1/N^2 the Rayleigh scattering cross section diminishes by 1/N^8. This reduction in the scattering cross section means that a laser emitting phat photons with N>1 will lose less energy traveling through the Earth's atmosphere than lasers using N=1. This reduction in energy losses through the atmosphere means increased efficiency for Earth based beamed applications.

8832-13, Session 3

Statistics of photon splitting and correlation filtering

Aloysius F. Kracklauer, Private Consultant (Germany)

We describe a possible statical effect capable of testing the widely accepted principle that, "photons cannot be split." This effect depends on the dispersion spectrum; if the photon is split, it will be essentially identical for both output channels of a beam splitter. On the other hand, if the photons are not split, these two distributions will differ by cause of a contribution from statistical effects in the crystal generating the individual pre-split photons. Mathematical analysis showing the consequences of various distributions of arrival time in both the source and detector, indicates that, it may be possible to distinguish split photons from random coincidences.

A possible experiment is described. In addition, the techniques used for the above will be applied to the generation of correlated photon pairs and used to analyze the data analysis algorithms for experiments involving quantum entanglement. Results point to possible non quantum generation of the data patterns currently thought to exclude non quantum clarifications

8832-14, Session 4

New experiments and questions to shed light on the nature of a photon

Carl F. Maes, College of Optical Sciences, The Univ. of Arizona (United States)

Is the nature of light observed only indirectly after its interaction with matter? We currently lack an experimental technique which would isolate the nature of light without the use of matter i.e., a detector.

We will present additional experiments which, although again indirect, may reveal new understandings (but mostly more questions) about the nature of light. This talk will not report research results, but rather be an invitation for others to conduct similar such measurements as will be proposed.

Can atomic recoil upon photo-emission be measured accurately? If so, what information about a photon's can be gained by measurement of the atomic recoil resulting from its emission without disturbing the photon?

What are the photon statistics in a dark fringe?

Is light reflected in the region of a dark fringe by a metal reflector?

8832-15, Session 4

Single-photon detection, truth, and misinterpretation

Erich H. Berloffa, Leopold-Franzens-Univ. Innsbruck (Austria)

In this investigation it is shown that modern photon detectors indeed can resolve the energy of a "single photon" , but this is only due to its tiny active area. From basic solid state physics it can be derived that special doping of semiconductor substartes is necessary for accomplishing this task. The fact we can detect single photon event does not mean that there is a 1:1 relation between the detected event and a corresponding "single" quantum transition. Propagation behaviours have been simply overlooked in the past. Practical examples are demonstrated on hand of a commercial pin-/and AVD photodiode.

8832-16, Session 4

The nature of the photon from viewpoint of a generalized particle mode

Albrecht Giese, Deutsches Elektronen-Synchrotron (Germany)

Particle physics deal about a few basic particle types:

- Leptons
- Quarks
- Photons

Most of the particles we know are leptons or are built by quarks (as e.g. mesons). A special place occupies the photon which seems to be independent. And – among other aspects – it has twice the spin of leptons and quarks.

Using the properties of particles such as their mass, spin, and magnetic moment, and from the relativistic behaviour of matter – which can be derived from the 'zitterbewegung' of the electron – we can draw up a model in which a particle is composed of a pair of sub-particles which orbit each other. This model conforms to the quantum mechanical concepts of Louis de Broglie. It replaces the idea of particle-wave-duality founded by the Copenhagen interpretation of QM. The model allows for a description of particle properties with high precision on the basic of classical physics.

This particle model which was developed for leptons and quarks has to be applied also onto the photon. The consequences for the understanding of the photon are an essential topic of this talk.

This model also has the capability to explain open issues like cosmological inflation, dark energy, and dark matter. And in contrast to the way as Albert Einstein has done it, relativity is not founded on 'principles' but follows from the structure of fields and particles and gets in this way a real physical basis.

8832-17, Session 4

Consequences of partitioning the photon into its electrical and magnetic vectors upon absorption by an electron

Daniel S. Szumski, Independent Scholar (United States)

This research develops a theory that unites in a single equation, the heat radiation theory of Planck and the heat-of-molecular-motion theory of Maxwell and Boltzmann.

Photon absorption is considered a two-step process. The first is an adiabatic reversible step, wherein one-dimensional light energy is absorbed in a quantum amount by an electron. The absorbed quanta is still 1-dimensional(1-D), and remains within the domain of reversible thermodynamics.

Absorption's second step is a dimensional restructuring wherein the electrical and magnetic vectors evolve separately. The 1-D electrical quanta transforms into 3-D electrical charge density, in accordance with the Equi-partition Theorem, and along the axes of the electron's three spatial coordinates. This displacement of the generalized coordinates translates to 3-D motion, the evolution of Joule heat, and irreversibility. The magnetic vector has no 3-D equivalent, and can only transform to 1-D paramagnetic spin. Accordingly, photon de-coupling distorts time's fabric, giving rise to the characteristic spectral emittance.

The new equation shows how non-equilibrium and far-from-equilibrium spectra are described by two temperatures: the thermodynamic temperature of the Rayleigh-Jeans Law, and a new quantity described as the radiation temperature (Wein Displacement Law temperature).

This treatment of photon absorption leads to an alternative understanding of covalent bonds. The author also speculates that the non-equilibrium spectral distribution could be useful in describing the far-from-equilibrium energy storage in living systems.

8832-61, Session PMon

Unification of fundamental interactions of nature

Akbar Rahmani-Nejad, Maharan Engineering Corp. (Iran, Islamic Republic of)

In this paper it is tried to introduce an interaction as the origin of fundamental interactions of nature (electromagnetic , gravitational, strong and weak nuclear forces). this has a distinct formula that by inserting charge in formula , coulomb or electric force is obtained. by inserting moving charge (charge and velocity) in the formula we will reach to magnetic force formalisms plus coloumb constant including faraday law, ampere law, gauss law etc. by inserting mass instead of charge, and considering long ranges and some statistical concepts gravitational force plus universal gravitational constant. by limiting the interaction rate to sub fm ranges, strong nuclear force will be formalized. It is obvious that all three forces of coulomb force, gravitational force and magnetic force on a moving charge all have common shape, all three forces are inversely proportional to square of distance all 3 are proportional to multiplication of charges or masses of two distinct particle or objects. Strong force is the same form of original force but when the distance is under fm due to inverse proportionality to square of distance the energy of the force will be in the range of Mev. Weak nuclear force is not considered to be a force, but just the result of increasing mass and effective interaction distances in respect to strong nuclear forces interaction distance and also in unbalancing nucleon's mass, charge and some other quantum numbers. It is impossible to explain formulas and methods in this brief explanation. But by reaching to the answer, there will be a new interpretation of mass, inertia, close and far interactions, fields, wave, energy, mass, space etc. for example mass will explained of a buckle of energy that space only can contain it in a specific point it (point of space) and two buckles of energy cannot occupy the same point of space. Field is only the direction of possibility of interactions. Space can be divided in two category, infinite and finite. Finite space can hold and interact with particles which have an integer multiplication of their wavelength leading to creation of particles having mass. Other new concepts like space-particle resonance will be introduced. Mass and photons are two distinct orthogonal mathematical-space of energy. All it can be mentioned is that there will be a new approach toward this subject and details can be mentioned in complete paper.

8832-62, Session PMon

A new approach to the concept of double-slit experiment by consideration of each slit as a very short waveguide

Akbar Rahmani-Nejad, Maharan Engineering Corp. (Iran, Islamic Republic of); Ali Rahmani Nejad, Doctor Mosaheb College (Iran, Islamic Republic of); Ahmad Rahmani Nejad, Islamic Azad Univ. (Iran, Islamic Republic of)

In this paper it is proved that by considering of each slit of double slit experiment as a very short millimeter or micrometer waveguide it is possible to reach a very precise explanation of optical beam propagating through slits and constituting modes of propagation – that is very similar to Schrodinger equation – it is possible to have very precise analysis and formulation of this phenomenon. This analysis shows that in the case of diffraction of one slit it is enough to consider that each TE or TM modes diverged after passing through slits, i.e. the shape of fringes will be calculated as precisely as observed in experiments. This will arouse us to have a new verification to Fraunhofer and Fresnel formulations for far field and near field diffractions and Huygens principle as well. On the other hand diverging light beams on output edges of each slit again prods us to have a new consideration to bending of light in the vicinity of matter that it is not necessarily to observe this phenomenon near massive objects as predicted by space curvature interpretation of general relativity.

8832-19, Session 5

Chemical and physical action of solar radiation according to the Gibbs method

Viktor Laptev, Halyna M. Khlyap, State Pedagogical Univ. (Germany)

Corpuscular nature of light (Newton) and wave nature of light (Huygens) is used in in a big number of technical devices where the light beams as electromagnetic waves (Maxwell) transfer quanta of energy (Planck). The particle of light is (according to Einstein) a quantum of the electromagnetic field's energy (Lewis). The laws of thermodynamics are applicable to the light beams as well as to the photonic gas. The work shows that the radiation can be in equilibrium with the photon condensate without phase boundary. According to this concept the condensate can be considered as an intermediate state when the matter (the substance) experiences physical and chemical action under absorption and emission of the photons.

The radiation is in thermal equilibrium with the substance and the substance experiences the pressure of the radiation because the photons have an impulse. The chemical potentials of the photonic gas and the condensate may be different. The idea of non-zero value of the chemical potential of thermal radiation was already discussed in the literature [1-4]. In this report the characteristic functions of the number of photons U(V, N) and H(p, N) which are necessary for calculation of the chemical potential were found. The temperature dependence of the chemical potential of thermal radiation u=3.602 kT is derived by the differentiation of these functions. One may hope that the characteristic functions of the number of photons and the chemical potential of thermal radiation will allow revealing unknown aspects of chemical, biochemical and electrical actions of thermal radiation in a wide range of temperatures.

Thermal radiation is treated as homogeneous phase equilibrium with a special feature: the pressure of the photonic gas is positive and the pressure of the photonic condensate is negative. From this point of view such medium is neither mixture nor usual solution. This statement is to be based on the theoretical investigation of the conditions of equilibrium and stability of the medium with sign-alternative pressure is carried out under using the thermodynamic laws and the Gibbs' equilibrium criterion. The sun radiation and its condensate are claimers on the medium with alternating-sign pressure.

The thermodynamic scale of efficiency $\zeta(T)$ of the chemical action of solar radiation presented in this work is a necessary tool for choice of optimal design of the solar engines-reactors. It is simple for application while its values are calculated from the data of chemical potentials and temperature obtained experimentally. Varying the values of chemical potentials and temperature makes it possible to model the properties of the working body, its thermodynamic state and optimal conditions for chemical changes in solar engines and reactors in order to bring commercial advantages of alternative energy sources with help of expressions [5]

$\zeta(T) = \eta C / \eta 0 = (uP - uR) / uS /(1-Tm / TS)$,

$\Delta GT = (uP - uR) + (um - uS)$.

- The cell is considered in biology as a biochemical engine. Chemistry and physics know attempts to present the plant photosynthesis as a working cycle of a solar heat engine [6]. The physical action of solar radiation on the matter of nonliving systems during antenna and working cycles of the heat engine is described in [7,8]. In this article the Carnot theorem has been used for calculation of the thermodynamic efficiency of the photosynthesis in plants; it is found that the efficiency is 71%. Earlier the limiting efficiency of green plant was defined to be 5% as a ratio of the absorbed solar energy and energy of photosynthesis products [9, 10].

- Technologies for producing electric contacts on the illuminated side of solar cells are based on chemical processes. Silver technologies are widely used for manufacturing crystalline silicon solar cells. The role of small particles in solar cells was described previously. The introduction of nanoparticles into pores of photon absorbers increases their efficiency. Copper microclusters were chemically introduced into pores of a silver contact. They changed the electrical properties of the contact: dark current, which is unknown for metals, was detected [11].

The two-body photon

Randy T. Dorn, Independent Researcher (United Arab Emirates)

The physical observations that light exerts pressure on objects and light is bent by gravity can be considered as evidence that photons do indeed have mass. The theoretical requirement for mass to be convertible to radiant energy which is net electrically neutral yet has alternating positive and negative potentials and an alternating magnetic field leads to the proposal that a photon is simply an electron and positron in a two body orbital union traveling through space. In this paper a simple mechanical model of a photon is presented. It comes directly from conservation of matter and observations of electron-positron annihilation and electron-positron pair production. If electrons and positrons are considered fundamental particles, there is no reason to believe that they change character between annihilation and pair production. Most interpretations of the mathematics of special relativity would lead one to believe that mass cannot travel at the speed of light because the mass or momentum would be infinite at that velocity. However, under the influence of an inverse square force, speed of light particles are actually predicted using accepted mathematical models. Furthermore, the equations of motion of charged particle interactions can be rearranged and interpreted so that the force varies with velocity instead of the mass. This change in perspective makes the concept of speed of light particles entirely plausible and allows a renewed appreciation for the concepts and definitions of classical mechanics.

8832-21, Session 5

Further investigation of an integrated picture of photon diffraction described by virtual particle momentum exchange

Michael J. Mobley, Arizona State Univ. (United States) and Grand Canyon Univ. (United States)

An alternative picture for photon diffraction had been proposed describing diffraction by a distribution of photon paths determined through a Fourier analysis of a scattering lattice where the momentum exchange probabilities are defined at the location of scattering, not the point of detection. This contrasts with the picture from classical optical wave theory that describes diffraction in terms of the Huygens-Fresnel principle and sums the phased contributions of electromagnetic waves to determine probabilities at the point of detection. This revised picture, termed "Momentum Exchange Theory," can be derived through a momentum representation of the diffraction formulas of optical wave theory, replacing the concept of Huygens wavelets with photon scattering through momentum exchange with the lattice. Starting with the Rayleigh-Sommerfeld and Fresnel-Kirchoff formulas and looking at several model experiments, this paper demonstrates that diffraction results from positive and negative photon dispersions through virtual particle exchange probabilities that depend on the lattice geometry and are constrained by the Heisenberg uncertainty principle. The positive and negative increments of momentum exchange exhibit harmonic probability distributions characteristic of a "random walk," dependent on the distance of momentum exchange. The analysis produces a simplified prediction for the observed intensity profile for a collimated laser beam diffracted by a long, straight edge that lends conceptual support for this alternative picture.

8832-22, Session 5

The photonic soliton

Andrew Meulenberg Jr., Univ. Sains Malaysia (Malaysia) and Hi Pi Consulting (United States)

The size stability of the photon has been a puzzle for many decades. However, the self-focusing of a laser beam in matter may provide some guidance to this problem. A conceptual basis for this effect will be accompanied by calculations based on the laser models. It does not necessarily fit. Nevertheless, it leads to better models. The notion of a self-generated light pipe for a photon supports the image of the photon as a soliton. Two photon models are developed. In one, there is a circulating high-energy density that creates a finite-radius light pipe, which thus confines the photon to a core, but with an extended evanescent wave about it. It confines by total internal reflection. In the other, the confinement mode is that of a self-generated graded refractive index (GRIN) optical lens, which does not produce an evanescent wave; but, the electromagnetic energy is spread into the region that would be occupied by the evanescent wave of the first model. The models may be equivalent; both indicate the nature of a relativistic boundary condition that should be imposed on Maxwell's equations to allow inclusion of photons into his model.

8832-23, Session 5

The photon concept revisited

Dmitri V. Voronine, Texas A&M Univ. (United States) and Baylor Univ. (United States); Marlan O. Scully, Texas A&M Univ. (United States) and Baylor Univ. (United States) and Princeton Univ. (United States)

The concept of one photon wave function has attracted interest for decades. People often ask if there exists a 'wave function for the photon' which can be used to understand the nature of the light. Wave function of the classical electrical field and quantum state of the matter system is described in a semiclassical theory. Therefore, many aspects of the photon can be understood with a classical electromagnetic field and the fluctuations associated with vacuum [1]. However, a complete description of radiation-matter interactions is provided by the quantum theory of radiation. To understand the photon concept deeply, we should quantize the radiation field such as E(+)(r,t) = [sigma]k[epsilon]kake-ivktUk(r) where ak are quantum field operators. Thus wave function for a single photon can be defined as [psi][epsilon](r,t) = <0|E(+)(r,t)|[psi]y>. Details are revisited here from Scully and Zubairy's quantum optics book [2] and further discussions are included.

8832-24, Session 5

The problematic "photon" *(Invited Paper)*

Arnt Inge Vistnes, Univ. I Oslo (Norway)

The concept of a "photon", as an indivisible particle of light, goes back as early as 1905, and the word "photon" was used already in 1926. The concept was not readily accepted. Even today there is no clear consensus on a proper representation of a photon, as the available theoretical formalisms provide little help due to the various interpretational problems that plague them.

The purpose of this talk is to give an overview of the various representations and interpretations that can be associated with the concept of the photon, and to highlight the phenomena that favor more specifically certain interpretations.

I will point out in particular the essential difference between argumentations that are based on physical mechanisms of interaction between fields and atoms, and those that rely on abstract and non-objective principles such as that of "indistinguishability".

I will discuss the difficulty of associating a photon to electromagnetic waves having large wavelengths, as the concept is then far more problematic than for visible light. I will also emphasize the problems associated with using Fourier decompositions to describe photon "modes", as this formalism is essentially meaningful only for continuous waves, and not for particle-like systems. I will illustrate those limitations by means of a comparison with wavelet transform.

Finally, I will insist on the large diversity of problems that arise when trying to go beyond the "wave-particle-dualism" in attempts to get a better understanding of Nature.

8832-25, Session 6

Subtlety in relativity *(Invited Paper)*

Sanjay M. Wagh, Central India Research Institute (India)

I will describe explanations of 1) Michelson-Morley type experiments, 2) Muon decay puzzle, and 3) Doppler's effect in light.

The explanation of the Michelson-Morley type experiments is based on the emission-wave mechanism. The resolution of the muon decay puzzle is based on Pauli's exclusion principle as applied to a system of interacting muon and electrons surrounding it during its passage in the Earth's atmosphere. The explanation of the Doppler shift in frequency is based on the analysis of proper locations on the light front.

Notably, these explanations do not involve either the time-dilation or the length contraction as in the Special Theory of Relativity. That is to say, these explanations do not use the Lorentz transformations. Nevertheless, they are based on the principle that the speed of light is the same for all the observers, whether accelerated or not.

8832-26, Session 6

Spacetime-based model of EM radiation

John A. Macken, Macken Instruments Inc. (United States)

A spacetime based model of an electric field and EM radiation is described. The model assumes that 4 dimensional spacetime has vacuum fluctuations at all frequencies up to Planck frequency. This implies that vacuum has energy density about 10^120 larger than the observable energy density of the universe. The reason that this vacuum energy is not directly observable is discussed.

Gravitational wave theory is used to give insights into EM radiation. We know that gravitational waves propagate in the medium of spacetime. From gravitational wave equations it is possible to derive the impedance of spacetime (Zs = c^3/G) and a wavelength dependent bulk modulus of spacetime. A proposed new constant of nature is derived that converts electric field strength to a quantifiable distortion of spacetime. One key finding is that this new constant shows that the impedance of free

space (Zo ≈ 377 Ω) converts to 4πZs. Therefore light must be wave propagation in the medium of spacetime because light experiences the same impedance as gravitational waves. The particle-like properties of a photon are examined and found to be the result of photons possessing quantized angular momentum.

An electric field is proposed to be a quantifiable polarization of spacetime. An experiment is suggested to test this prediction. This model also implies that gravitational waves should affect the polarization of circularly polarized light. If this effect exists, then a suggested modification of the LIGO experiment would greatly increase its sensitivity.

8832-27, Session 6

Can highly-relativistic particles explain part of the dark Universe

Karl Otto Greulich, Fritz Lipmann Institute (Germany)

In attempts to explain dark matter, an important componen is often neglected: particles such as ultrafast protons/neutrons which have a relativistic mass larger than the Planck mass and are thus invisible. At a critical speed the mass of a particle exceeds that of the Planck mass. Its Schwarzschild radius then becomes larger than its de Broglie wavelength, i.e the particle becomes invisible. For protons/neutrons this is approx. 10 exp19 times of its mass at rest. With the assumption that particles with a rest mass of only the order of 10 000 Sun masses still have kept, since the big bang, such a high speed, it can be explained that the major part of the Universes mass appears as "dark". It also becomes plausible that even today visible mass is generated from virtually the vacuum, simply by decelerating down such fast particles by collisions with slow matter.

8832-28, Session 6

The electrostatic to gravitational force ratio within the Electro-Gravi-Magnetic (EGM) construct *(Invited Paper)*

Riccardo C. Storti, Delta Group Engineering, P/L (Australia)

The Electro-Gravi-Magnetic (EGM) construct is a derived methodology based upon the Polarizable Vacuum (PV) model of gravity and Buckingham Pi Theory (BPT). Their union has produced impressive experimentally verified results consistent with the Standard Models of Particle-Physics and Cosmology. The body of research in this paper is based on the fundamental EGM prediction that Photons are quantized massive propagating units of matter such that, when standard engineering scaling and similarity techniques are applied, the "Many Orders of Magnitude" problem between ElectroStatic and Gravitational Forces is reconciled as a function of Cosmological Expansion.

8832-29, Session 6

Resonant energy absorption and the CTF hypothesis

Michael Ambroselli, Chandrasekhar Roychoudhuri, Univ. of Connecticut (United States)

Antennas in resonant circuits can present an effective aperture (antenna area) much larger than its physical dimensions, in order to absorb energy from the electromagnetic field. Similarly, atoms can absorb energy from fields with energy densities so low that the atom must have an effective diameter on the order of tens of microns. It appears that resonant energy absorption exhibits a sort of 'suction' effect, which causes field energy to converge from a larger into a smaller region. We will discuss how this provides further evidence for the utility of our proposition of a universal, complex tension field (CTF), which can support a multitude of gradients, including the electromagnetic field.

8832-63, Session 6

The influence of gravitation on electromagnetism

Guido Zbiral, Consultant (Austria)

Although photons can be extremely energetic and each form of energy is inseparably associated with gravitation, the Theory of Special Relativity nevertheless assumes that the gravitation of photons - always supposed to be static in nature - is vanishingly negligible. For this reason the photon's gravitation is completely ignored in that theory. This paper, however, casts doubt on the correctness of this assumption and will examine the actual role played by gravitation in electromagnetism.

In the course of this paper, an analysis will lead to the new insight that the gravitation of a photon is as dynamic as the photon itself, but static gravitation does not exist for photons. The dynamic gravitation of a photon appears as gravitational radiation locally bound to the photon and is in close interaction with the photon's electromagnetic radiation. Dynamic gravitation represents the hitherto unknown physical quantity acting in an opposite manner to electrodynamics, thus closing an evident gap in physics.

Furthermore, it will be shown that dynamic gravitation determines the physical properties of photons, such as the speed of light, and must therefore be taken into account with all associated physical considerations. The dynamic gravitation of photons is produced by gravitational quanta, and thus appears in quantised form. Consequently there must exist exactly the same number of gravitational quanta as there are of photons themselves. It is therefore necessary to rethink the physics of photons.

8832-30, Session 7

Epistemological considerations on the foundations of physics *(Invited Paper)*

Ted Silverman, IIAS (United States)

The conceptual foundations of physics are compromised by profound logical difficulties, too many of which have been romantically attributed to the mysteries of a universe "stranger than we can imagine." While foundational problems have always existed in physics the extent to which they currently impede research is well beyond a tolerable limit. Efforts to push past these problems without directly addressing them have little chance for long term success. A tangle of subtly linked conceptual cords must be carefully dissected before fruitful efforts toward unification can proceed.

8832-31, Session 7

Emergent un-quantum mechanics

John Ralston, The Univ. of Kansas (United States)

There is great interest in ``emergent" dynamical systems and the possibility of quantum mechanics as emergent phenomena. We engage the topic by making a sharp distinction between models of microphysics, and the so-called quantum framework. We find the models have all the information. Given that the framework of quantum theory is mathematically self-consistent we propose it should be viewed as an information management tool not derived from physics nor depending on physics. That encourages practical applications of quantum-style information management to near arbitrary data systems. As part of developing the physics, we show there is no intrinsic distinction between quantum dynamics and classical dynamics in its general form, and there is no observable function for the unit converter known as Planck's constant. The main accomplishment of quantum-style theory is a expanding the notion of probability. A map exists going from macroscopic information as ``data" to quantum probability. The map allows a hidden variable description for quantum states, and broadens the scope of quantum information theory. Probabilities defined for

mutually exclusive objects equal the classical ones, while probabilities of objects in more general equivalence classes yield the quantum values. Quantum probability is a remarkably efficient data processing device; the {it Principle of Minimum Entropy} explains how it serves to construct order out of chaos.

8832-32, Session 7

Global sustainability and advances in quantum physics

Juliana H. J. Mortenson, General Resonance, LLC (United States)

Models of global sustainability suggest a near term crash of global economies caused by depletion of world energy resources, rapidly declining industrial output, and food shortages. In scenarios which do not end in catastrophic crash, technology is the key factor which allows the world to avoid a significant decline in global economies: technology which reduces the use of energy resources per unit of industrial or food output, decreases pollution, and increases land yield. To avoid collapse and ensure global sustainability, the ratio of energy input to product output ("EI/PO") must be lowered. Based on scientific consensus regarding energy and thermodynamics, such a technology solution is unlikely, if not impossible. It has previously been shown however that the foundations of twentieth century physics were incomplete and new quantum variables and foundational equations have been discovered. Recent work with these variables has radically changed scientific understandings of energy, thermodynamics, and quantum relationships. The complete physics which is emerging provides scientific mechanisms by which the ratio of energy input to product output can be lowered, and has opened the door to previously unexplored concepts in energy dynamics and resonance science. This on-going scientific revolution may provide the technologies required to sustain global economic development, energy production, resource use, pollution remediation, and industrial and food output.

8832-33, Session 7

Quantum Indeterminism: a direct consequence of Fourier ontology *(Invited Paper)*

Jose R. Croca, Univ. de Lisboa (Portugal)

Quantum mechanics is founded on the Complementarity Principle proposed by NielsBohr for the first time at Volta Conference, September 1927. The mathematical expression of this founding principle are Heisenberg indeterminacy relations. By its turn Heisenberg relations, as shown by Bohr, are a simple consequence of Fourier ontology. In this stealthy way nonlocality, both in time and space, are deeply rooted in quantum mechanics.

In such circumstances the only way to recover causality and a fair locality is to substitute Fourier ontology and assume, since the very beginning, that a finite wave may have a well-defined frequency. The use of local wavelet analyses, in particular Morlet wavelets, allows the derivation of a more general set of uncertainty relations that formally contain Heisenberg relations as a particular case.

Since physical theories are validated or invalidated by experiments let them talk! Experiments have shown to the evidence that the limits imposed by Heisenberg relations can be overcome. Indeed, in modern technology, namely the one related with computers and memory devices, is common for the vanguard to refer that they are working beyond Heisenberg limits, or Fourier diffraction limits. Furthermore, other experiments, that shall be discussed, are devised to test the general validity of Heisenberg relations, and consequently Fourier ontology.

8832-34, Session 7

Viewing the terrestrial and cosmological phenomena through the eyes of photon wave packets

Chandrasekhar Roychoudhuri, Univ. of Connecticut (United States)

How would photon wave-packets describe terrestrial and cosmological phenomena based on their physical experiences? The presentation will be done by a biased, subjectively driven neural network. So the objectivity behind the methodology of thinking will be defined. Our ontological thinking is still an emerging phenomenon and must continue to be refined iteratively through generations. We must anchor our logical thinking and modeling approach to map the physical interaction processes in nature by visualizing these otherwise invisible processes. Emulation of nature allowed processes is behind our successful invention of technologies, which, in turn, is at the core of our successful evolution since the early days of evolution starting with the various single cells. Hence it is critically important for us to incorporate process mapping methodology on to the immensely successful modern methodology of modeling observable data. But why choose photons and not electrons? Various photons, in contrast to particles, (i) can bring accurate information about the original or secondary "parents" as in QM, Astrophysics, and optical sensors; (ii) can deliver information as in optical communication; and (iii) can deliver energy as in laser material processing. Our story will be woven based on their mutual non-interacting properties, in contrast to interacting particles. Distinguishing between the mathematical superposition principle and physical superposition effects, experienced by detectors, is our key logical platform. We demonstrate that a large number of ad hoc hypotheses from Classical-, QM-, Relativity- and Astro-Physics can be safely removed to make physics more causal and understandable through common sense logics.

Non-interaction of EM waves in the linear domain requires new properties for the cosmic vacuum as a physical and stationary Complex Tension Field (CTF), rather than treating it as a pure vacuum. Acceptance of CTF then enforces a cascade of changes in the prevailing physics hypotheses pertaining to Classical, Relativity, QM and Cosmology, while preserving all the measured phenomena, including the constancy of the velocity of light. 3-D space becomes more relevant than the hypothesis of 4-D space. Optical Doppler shift becomes separately dependent upon the source and the sensor velocities; which then requires us to explain

cosmological redshift as distance dependent dissipative frequency loss, rather than due to optical Doppler shift, obviating the hypothesis for an expanding universe. The hypothesis of wave-particle duality becomes unnecessary to explain physical superposition effects, which, in reality, are transformations experienced by detectors under the influence of simultaneous stimulation by multiple entities at the same time. Most of the apparent mystical behaviors behind light-matter interactions become causal and local, making QM a causal. In classical physics propagation of space and time finite causal signal, instead of non-causal Fourier monochromatic wave existing in all space, makes mathematical models for spectrometry, coherence, dispersion, polarization more appealing while using fewer hypotheses than we do now. Thus, non-interaction of waves becomes a powerful "Occam's razor", while making prevailing physics theories, across the board, to conform to common sense and at the same time underscores the direction of new exploration and development. The symbols in a mathematical theory should correspond, as closely as possible, to the physical parameters of entities under study and the mathematical operators must corroborate real physical interactions between them.

8832-35, Session 7

The Mandelbrot set and the fractal nature of light, the Universe, and everything

Lori Gardi, Robarts Research Institute (Canada)

There is always another way to say the same thing that doesn't look at all like the way it was said before." Richard Feynman. In this essay, a novel approach to cosmology is presented that models the Universe as an iterated function system (IFS) analogous to the famous Mandelbrot Set IFS: z=z2+c, where z and c are complex numbers (M). In theoretical physics, wavefunctions are functions of the complex plane that are commonly used to model the dynamics of particles and waves. In the IFS framework presented herein, complex dynamical systems are generated via the iteration process where the act of iteration corresponds to 1) a change in the state of the system and 2) a change to the wavefunction itself. In this manner, M can be thought of as a wavefunction generator. In this framework, all observables, including gravity and time, are thought to be generated by the iteration process. Feynman understood that there are many ways of looking at the Universe that are equivalent in nature but different psychologically. Understanding cosmology in terms of fractals and iterated function systems requires a paradigm shift in the way we approach cosmology. This is an evidence based dissertation and does not contradict the standard model; rather, it attempts to reconstruct it using the principles of the fractal paradigm as outlined in this essay. It is the contention of the author that in order to understand the true nature of light, the Universe and everything, we must first understand the important role that fractal cosmology plays in the study of our complex dynamical Universe.

8832-36, Session 7

Dark side of quantum mechanics: categorification, reinterpretation, and all that in the sheaf framework

Michael G. Zeitlin, Antonina N. Fedorova, Institute of Problems of Mechanical Engineering (Russian Federation)

We present an attempt of reinterpretation of the standard folklore of the elementary Quantum Mechanics, considered as some ground zero approximation for Local Quantum Field Theory.

First of all, we get rid of the structureless geometrical point as a proper model for the real quantum/physical particle like electron or photon. To do that we need to substitute standard (wave) functions describing states in orthodox formulations by more complicated objects to have a chance to encode information about the possible internal structure of quantum objects in our formal mathematical description.

Here we continue our program (started in arXiv:1109.5035, arXiv:1109.5042) of reconsideration of Quantum Mechanics via some categorification in the powerful sheaf framework.

It allows us to introduce hidden structures, like hidden degrees of freedom and hidden symmetries, into the game and, as a result, to have a chance for a more careful description and interpretation of the well-known set of standard phenomena, including, e.g., self-interference/interaction, entanglement, decoherence.

We start with the description of our base categories also proper for more analytical/computation tools described in companion paper.

After that, we introduce various families of sheaves which allow us to describe our version of the Quantum World, where the category of coherent sheaves play the crucial role in the qudit case while quasi-coherent sheaves are proper for the continuous variable case.

It seems that such a framework together with sheaf language allows us to obtain a natural interpretation for the whole set of phenomena, including transition to the (quasi) classical description, e.g., we will consider the wave function collapse/decoherence/measurement as the inductive limits of some families of sheaves.

In addition, we consider bridges to the more tradition quantization procedures like geometrical and deformation ones.

In companion paper, we apply that machinery to an analysis of the hidden multiscale structure of quantum Wigner-Weyl-Moyal dynamics beyond of the gaussian approximation.

8832-37, Session 8

Quantum theory as the most robust description of reproducible experiments *(Invited Paper)*

Hans De Raedt, Univ. of Groningen (Netherlands); Mikhail I. Katsnelson, Radboud Univ. Nijmegen (Netherlands); Kristel F. Michielsen, Forschungszentrum Jülich GmbH (Germany)

It is shown that the basic equations of quantum theory can be obtained from a straightforward application of logical inference to experiments for which there is uncertainty about individual events and for which the observed frequencies of events are robust with respect to small changes in the conditions under which the experiments are carried out.

8832-38, Session 8

Probability and current density of a single photon

Gavriil Shchedrin, Texas A&M Univ. (United States) and Princeton Univ. (United States); Marlan O. Scully, Texas A&M Univ. (United States) and Princeton Univ. (United States) and Baylor Univ. (United States)

We introduce the concept of the probability and current density of a single photon. The wave function of a single photon is represented by the direct product of the three-component electric and magnetic spinors. We show that the Maxwell equations formulated in terms of electric and magnetic spinors of a single photon can be written in terms of the time-dependent Schr odinger equation for a six-component bispinor. This formulation naturally leads to the current and the probability density for a single photon that satisfies the continuity equation.

8832-39, Session 8

The topological basis of the photon

Robert M. Kiehn, Univ. of Houston (United States)

All physical measurements depend upon finite intervals of space and time. There are only two types of finite power set topologies;

(Kolmogorov) T0 topologies with separation axioms, and Not-T0 topologies without separation axioms. Finite T0 topologies have singlet subsets which are distinguishable in the sense of Particles. Finite Not-T0 topologies have singlet subsets which are indistinguishable in the sense of Waves and Ensembles. In this article, focus is placed on the Not-T0 topologies and their association with waves and photons. Numerous examples will be presented.

8832-40, Session 8

Geometro-dynamics of energy of fermions and photons

Viraj P. Fernando, Natural Philosophy Alliance (Canada)

It is the common belief in today's physics that the energy-momentum equation holds only for fast moving fermion particles. However, this equation is found to be is true for all velocities 0< v< c , upon discerning that there is a fundamental trigonometric relationship pc = mc2 tan?, between the two terms on the left hand side of the equation, which also prompts that the right hand side is mc2.sec2?. Once these relationships are deciphered, we find that the second order term v2/c2 which has hitherto been required to be neglected for the validity of classical mechanics for optical phenomena now assumes its true relational expression as sin2?. By means of geometric representation, this approach enables the visualization of all the phenomena involved in a given interaction in their concatenation. In contrast to a fermion, even though a photon moves by its own intrinsic energy, and undergoes a change of state of motion without the direct application of motive energy pc externally, in photon interactions too an algorithm similar to the fermion algorithm is found to be simulated, and energy effluxes and influxes to and from the field are effected as determined by it. The veracity of the above- mentioned algorithms are demonstrated by applying them in combination to the collision of a photon and an electron as in Compton's experiment. In every interaction without exception, a photon undergoes either an emission of a fraction of its energy (energy-defect) to the field or an absorption of a fraction of energy (energy-absorb) from the field.

8832-41, Session 8

Revising your world view of the fundamental constants

John Ralston, The Univ. of Kansas (United States)

The nature of physical units and fundamental constants may seem elementary, but it is not. For a century units and constants have been delegated to international committees unconcerned with the evolution of theoretical physics. The current situation has locked physics into a perspective a century in the past.

It is almost impossible for those in engineering and applied physics to get consistent information that is not conflicted by contradictory and failed theories of the early 20th century.

By critically re-examining the actual structure of the present system in a new light, we find that unit systems and concepts endemic in Newtonian physics impede the understanding and use of quantum theory. Confronting this finds that Planck's constant cannot be observed in quantum theory, and is entirely a construct of human convention. A cascade of seeming paradoxes and contradictions occurs when Planck's constant is eliminated, yet the end result is a simpler and cleaner vision of what quantum mechanics and quantum field theory really involve. By eliminating redundant holdovers the number and nature of fundamental constants is revised: the fine structure constant is determined more than 100 times more accurately.

The nature of "mass" and mass parameters is changed to eliminate mistakes of the era before quantum mechanics, and dispense with all mystical mumbo-jumbo

8832-42, Session 8

A tower of hidden scales: non-Gaussian patterns in quantum mechanics

Antonina N. Fedorova, Michael G. Zeitlin, Institute of Problems of Mechanical Engineering (Russian Federation)

We present an application of our sheaf-based categorification framework considered in the companion paper to analysis of quantum dynamics inside the Wigner-Weyl-Moyal set-up. The key ingredient of our approach is related to a construction of functorial correspondence between two categories: the first one is described by families of quantum states realized as sections of some category of sheaves, allowing to cover the standard set of quantum phenomena while the second one is a proper arena for the investigation of (non-trivial, non-gaussian) solutions of Wigner-like equations in (at least) the minimal possible pseudodifferential set-up according to the ideology of microlocal analysis. To do that we need to consider together with the usual Hilbert space some underlying topological Hilbertian space with some filtration into subspaces, generated by the action of internal hidden symmetry. As a result, we obtain the analytical description of the whole tower of underlying scales together with the possibility to describe the full quantum evolution, taking into account the abundant hidden quantum structure. It seems that the existence of such rich internal structure is an essential part of any quantum phenomenon in contrast with the classical one.

So, we decompose quantum evolution into a full set of multiscales according to orbits constructed by the action of internal hidden symmetry on the properly filtrated underlying Hilbertian space of states.

Numerical modeling demonstrates the appearance of a big zoo of nontrivial patterns which enlarge an orthodox set of standard states like coherent ones, gaussians, etc. and allow us to have an additional chance for a possible reinterpretation and description of standard things like entanglement, decoherence, (von Neumann) measurements together with an attempt to understand the main features, e.g., hidden content, of base Quantum Mechanics.

What is a particle? A lesson from the photon *(Invited Paper)*

Karl Otto Greulich, Fritz Lipmann Institute (Germany)

In earlier contributions to this conference series (1,2) a photon model was presented where two Planck charges (Q= e/SQRT fine structure constant) oscillate against each other. It could explain, why electromagnetic radiation is transverse, why E=hv, why the spin of the photon is 1,and why it is self propelliing. Now it is shown that a similar model, again based on the Planck charge,explains essential features of the hydrogen atom and predicts the mass of the electron exactly and that of the proton to better than 0,3 %. Most masses of the heavy (beyond the up and down) quarks and the W, Z and Higgs Boson are predicted with accuracies better than 2 %.One of fhe predicted masses at 70 MeV/c2 cannot be ascribed to a known particle. However, its 1-5 fold is the muon, its twofold is the pion. All other particles are integer multiples of this mass-(2,3)

8832-44, Session 9

The physical origins of the Uncertainty Theorem

Albrecht Giese, Deutsches Elektronen-Synchrotron (Germany)

Elementary particles can be explained by an interpretation of quantum mechanics founded by Louis de Broglie, the discoverer of the wave properties of a particle.

According to this, elementary particles can be described using a predominantly classical model. This model is derived from the presence of relativity in all matter, and furthermore from properties such as mass, spin, and magnetic moment. According to this model an elementary particle is made up of a pair of sub-particles which orbit each other. The internal field which binds the sub-particles extends outward from the particle. It causes the particle to appear from the outside like a wave, and to undergo interference, for example when passing through a double slit. This understanding conforms to the approach of Louis de Broglie, who characterized the external part of the alternating field as a “pilot wave”.

The problem with measuring the dynamic parameters of an elementary particle is that those parameters are determined by the reaction of its surrounding wave. This surrounding wave on the one hand extends outward from the particle, but on the other hand it is locally concentrated around the position of the particle. This fact, the spatial delimitation, limits the determination of the wave parameters using the rules of the Fourier transform. Hence it reduces the information that can be obtained about the parameters to a degree described by the uncertainty of the measurement of the wave. The properties of the particle itself, however, are not at all uncertain in this view.

This derivation of uncertainty does not support the very general consequences drawn from the uncertainty principle as used by contemporary QM.

To apply this understanding to the photon, we have to assume that the photon has a kind of core, like leptons and quarks. This gives rise to further questions which need to be discussed.

8832-45, Session 9

On the possibility of laser-assisted production and detection of low-energy neutrino beams

Jeff W. Eerkens, Prodev Consultants (United States)

Experiments are discussed to prove or disprove the production and detection of collimated beams of low-energy (eV - keV) neutrinos with the assistance of lasers. Results of quantum-mechanical calculations are given of the relative probability that recoiling counter-propagating neutrino-antineutrino pairs are created instead of laser photons in stimulated emission events, under full obedience of energy, momentum, and spin conservation. This effect generates coherent monochromatic neutrino beams that overlap the internal standing-wave photon beam during stimulated de-excitations of lasing excited states. For a neodymium laser the probability is approximately 10-7. To detect such beams of monochromatic neutrinos and antineutrinos without requiring (anti)neutrino absorptions, one exploits (anti)neutrino-stimulated de-excitations of lasing levels in a second laser aligned with the first one. Excess emitted photons in the second laser induced by resonant (anti) neutrino fly-throughs can be measured by a laser power meter. By preventing photons from the first laser to enter the second one (e.g. by interposing a brick), one can discriminate and observe the effects of resonant fly-through neutrinos crossing the second laser. (Anti)neutrinos pass through nearly all matter (except for MeV (anti)neutrinos that strike nuclei). They can not be absorbed because they possess spin s = 1/2 and excitations/de-excitations in molecules require)s = Vn where n is an integer. This allows them to pass through the earth unimpeded. While absorptions are impossible, they can stimulate de-excitations of excited states without being absorbed if their undulation frequency is resonant with a lasing transition.

8832-46, Session 9

Inadequacies in De Broglie’s theory: rectifications, verifications, and applications

Ravindra K. Sinha, Himanshu Chauhan, Delhi Technological Univ. (India)

The genuine inadequacies persisting in De Broglie’s theory is presented in this paper. De Broglie’s proposed frequency (hν=ymc2) and phase velocity (c2/ν) expressions for matter wave are primarily shown to be inconsistent; and emerged out because of a major inadequate concept of similarity between photon and matter-body. He treated body and photon to be analogous which is inconsistent; in view of the ‘matterlessness’ of photon. The rectifications in the concepts are presented by treating the corpuscle of matter wave as a separate entity, though associated with the body, in a moving mass system. This corpuscle is shown to be actually analogous to photon instead of body itself.

The concept thus provides modified frequency ((hν=(y-1)mc2) and phase velocity expression for matter waves.

The proposed frequency and phase velocity expressions are verified by deriving it from the experimentally verified wavelength and conceptually adequate group velocity (νg=ν) expression. By the integration of thus obtained equation yields out the proposed modified frequency expression.

It is further shown that the substitution of the proposed modified phase velocity expression in the universal wave equation can yield the time dependent Schrödinger’s equation; however, de Broglie’s expression cannot. This shows the appropriateness of the proposed modified phase velocity expression.

Through the proposed modifications a Novel General Quantum Mechanical Wave Equation is derived out, and it is shown that the above proposed wave equation can yield out both Schrödinger’s and Dirac’s Equation Precisely.

8832-47, Session 10

Higgs Boson: God particle or divine comedy? *(Invited Paper)*

Chary Rangacharyulu, Univ. of Saskatchewan (Canada)

While particle physicists around the world rejoice the announcement of discovery of Higgs particle as a momentous event, it is also an opportune moment to assess the physicists’ conception of nature. Particle theorists, in their ingenious efforts to unravel mysteries of the physical universe at a very fundamental level, resort to macroscopic many body theoretical methods of solid state physicists. Their efforts render the universe a superconductor of correlated quasi-particle pairs. Experimentalists, devoted to ascertain the elementary constituents and symmetries, depend heavily on numerical simulations based on those models and conform to theoretical slang in planning and interpretation of measurements . It is to the extent that the boundaries between theory/ modeling and experiment are blurred. Is it possible that they meandering in Dante’s Inferno?

8832-48, Session 10

Geometrical and quantum mechanical aspects in observers’ mathematics

Boris Khots, Compressor Controls Corp. (United States); Dmitriy Khots, Consultant (United States)

When we create mathematical models for Quantum Mechanics we assume that the mathematical apparatus used in modeling, at least the simplest mathematical apparatus, is infallible. In particular, this relates to the use of “infinitely small” and “infinitely large” quantities in arithmetic and the use of Newton – Cauchy definitions of a limit and derivative in

analysis. We believe that is where the main problem lies in contemporary study of nature. We have introduced a new concept of Observer's Mathematics (see www.mathrelativity.com). Observer's Mathematics creates new arithmetic, algebra, geometry, topology, analysis and logic which do not contain the concept of continuum, but locally coincide with the standard fields.

We prove that Euclidean Geometry works in sufficiently small neighborhood of the given line, but when we enlarge the neighborhood, non-Euclidean Geometry takes over. We prove that the physical speed is a random variable, cannot exceed some constant, and this constant doesn't depend on an inertial coordinate system. Certain results and communications pertaining to these theorems are provided

We proved the following theorems:

Theorem A (Lagrangian). Let L be a Lagrange function of free material point with mass m and speed v. Then the probability P of L = mv2/2 is less than 1: P (L = mv2/2) < 1.

Theorem B (Nadezhda effect). On the plane (x, y) on every line y = k x there is a point (x0, y0) with no existing Euclidean distance between origin (0, 0) and this point.

Conjecture (Black hole). Our space-time nature is a black hole: light can't go out far from origin.

8832-49, Session 10

Can one distinguish between Doppler shifts due to source-only and detector-only velocities?

Chandrasekhar Roychoudhuri, Michael Ambroselli, Univ. of Connecticut (United States)

The Ne-atoms in a He-Ne discharge tube and light emitting atoms in different galaxies are QM law-abiding entities. Atoms participating in spontaneous and stimulated emissions must release and perceive photon wave packets as having the same QM-allowed frequency , even when they are statistically executing Maxwellian velocity distribution. Thus, a spontaneously emitted energy packet from a moving Ne-atom will evolve in the CTF as a photon wave packet carrying a true Doppler shifted frequency . But an excited Ne-atom would be able to respond to this Doppler shifted frequency as only if it is executing the same vectorial velocity as the original emitter of this wave packet. It has to nullify the physical Doppler shift of the wave packet by traveling in the same direction with the same velocity. In other words, the 'successful detector' Ne-atom 'to be stimulated' executes a dipolar stimulation at an apparent frequency , such that . All other excited Ne-atoms ignore this stimulating wave frequency as they are non-resonant and are not as prescribed by QM for successful stimulated emission. This is at the root of "inhomogeneously broadened" Ne-gain medium, which gives rise to multiple longitudinal modes in He-Ne lasers. Thus, optical Doppler shift is a function of both the velocities of source and the detector, instead of the relative velocity alone, as in standard classical Doppler shift formulation. We do not use Relativistic Doppler shift formulation, as we find that it cannot model the physical processes that the spontaneous and stimulating Ne-atoms carry out during their lasing operations. Thus distance dependent Cosmological Red Shift should not be explained as due to Doppler effect given by only the relative velocity between any pair of galaxies. We propose a distance dependent dissipative effect, implying that the universe could be "stationary". We then present a simple formulation to account for the distant dependent Hubble red shift by accommodating Hubble constant in our equation.

8832-50, Session 10

On reconciling quantum mechanics and local realism

Donald A. Graft, STMicroelectronics (United States)

Acceptance of nonlocal quantum correlations requires us to reject special relativity and/or probability theory. We can retain both by modifying quantum mechanics to change the handling of separated systems, as quantum mechanics stands in conflict with local realism only in its treatment of separated systems. We must not use the joint probability formula for cases of separated measurements; instead we use the marginals (partial traces) together with whatever priors we have from an understanding of the system. Such a program can reconcile quantum mechanics with local realism. An apparent obstacle to this program is the experimental evidence, but we argue that the experiments have been misinterpreted, and that when correctly interpreted they confirm local realism. By way of example, we describe a local realistic account of one important EPRB experiment (Weihs et al) that is claimed to demonstrate nonlocal entanglement. We present a local realistic system (experiment) that can be calibrated into both quantum and classical domains via adjustment of parameters ("hidden variables") of the apparatus. Weihs incorrectly dismisses these parameters as uncritical. The idea of nonlocal entanglement is seen to be an error. The rest of quantum mechanics remains intact, and remains highly valued as a powerful probability calculus for observables. Without the incoherent idea of nonlocal entanglement, we can leverage powerful classical ideas, such as semiclassical radiation theory, stochastic dynamics, classical noncommutativity/contextuality, measurement effects on state, etc., to augment or complement quantum mechanics. The modified quantum mechanics can live in peaceful harmony with the local realist conception, each offering useful paradigms for describing systems.

8832-51, Session 11

Wave-particle dualism unraveled by Young's double slit experiment *(Invited Paper)*

Axel Heuer, Univ. Potsdam (Germany)

Particle and wave like properties of photons can impressively be demonstrated in Young's double slit experiment. Usually measurements behind the slit provide information either about the path of the single photons or interference can be observed. Today the question of "which-slit" versus "interference" in the double-slit configuration is as relevant as it was in the early days of quantum mechanics [1].

For gaining some deeper insight we set up an experiment using a pair of photons generated by SPDC pumped with a higher order mode (TEM10) [2,3]. One of the SPDC photons, the signal photon, was applied for illuminating the double slit and measuring the single photon interference behind it. The other photon, the idler photon, was used in a reference measurement at the position of the slit using a polarizing beam splitter.

First, the signal photons were obtained at the position of the slit as a function of the position of the entangled idler photons in a coincidence measurement. From this coincidence measurement the "which-slit" information is available.

In a second coincidence measurement the far field interference fringes were obtained for signal photons passing through one of the slits, only, selected by the position of the reference detector measuring the entangled idler photons.

The newest results will be presented and discussed. This may provide new insights in the wave – particle dualism and thus inspire the discussion about the nature of photons.

This entirely new situation as regards the description of physical phenomena: The EPR experiment and quantum probability *(Invited Paper)*

Arkady Plotnitsky, Purdue Univ. (United States)

In his reply to A. Einstein, B. Podolsky, and N. Rosen's (EPR's) argument concerning the famous thought experiment that they proposed, the EPR experiment, N. Bohr spoke of it as revealing an "entirely new situation as regards the description of physical phenomena," which he attempted to explain in terms of his famous concept of complementarity. (How successful he was in this attempt is still under debate.) This paper will offer an analysis of the EPR experiment and the Bohr-Einstein exchanges concerning it from a perspective that is rarely considered in the discussion of the experiment, as originally conceived by EPR—that of probability. The role of probability, which came into play in the later versions of the experiment (which used discrete variables, rather than continuous ones as in the original version), and related developments, such Bell's theorem and the Kochen-Specker theorem, was obscured in the discussion of the original EPR experiment, including by Einstein and Bohr. This was primarily because this experiment dealt with predictions with probability equal to unity. Nevertheless, as I argue in this paper, probabilistic considerations are crucial in considering the experiment, and they played a key, if implicit, role in Bohr's argument. As is well known, the EPR thought experiment (for continuous variables) could not be performed in a laboratory, because the particular quantum state considered by EPR is not normalizable. However, certain parametric down-conversion experiments with photons statistically approximate the original EPR experiment for continuous variables, and as such, I shall argue, expressly bring into the foreground the probabilistic dimensions of the original EPR thought experiment, as do other paradigmatic quantum experiments, beginning with the double-slit experiment. I shall consider these actual quantum experiments from this perspective. I conclude with a brief discussion of what the problematic of the EPR experiment tells us about the nature of photons as quantum objects.

8832-53, Session 11

Entangled photons and antibunching phenomena revisited on the basis of various models for light

Andreas P. Thörn, Arnt Inge Vistnes, Univ. I Oslo (Norway)

At what level of energy does a classical experiment become quantum mechanical? Where does classical electromagnetic theory apply and where do we have to turn to quantum mechanics? Is there a sharp line between these two theories? And if so: why, and why at this level? Or if not: what are the common features of the formalisms, and what are the differences? With our upcoming experimental work, we hope to be able to gain some insight into these challenging questions.

We plan to study the transition from classical electromagnetic pulses to single photon level pulses in various experimental setups known to reveal non-classical effects (e.g. antibunching experiment, violation of Bell inequalities). Using a pulsed laser and starting out with moderate pulse power (i.e. with a vast number of photons in each pulse), the experiment will undoubtedly be describable with classical electromagnetic theory. However, as we steadily reduce the power, classical theory may cease to be valid, and quantum mechanics may have to be applied to describe pulses that contain only a single photon or less on average. Investigating if and under which conditions this might happen will hopefully shed some light on where the conflict between classical and quantum theories lies.

I will present in detail our planned experiment and our preliminary results.

8832-54, Session 11

Can violations of Bell's inequalities be considered as a final proof of quantum physics?

François F. Hénault, Lab. d'Astrophysique de l'Observatoire de Grenoble (France)

Nowadays, it is commonly admitted that the experimental violation of Bell's inequalities that was successfully demonstrated in the last decades by many experimenters, are indeed the ultimate proof of quantum physics and of its ability to describe the whole microscopic world and beyond. But the historical and scientific story may not be envisioned so clearly: it starts with the original paper of Einstein, Podolsky and Rosen (EPR) aiming at demonstrating that the formalism of quantum theory is incomplete. It then goes through the works of D. Bohm, to finally proceed to the famous John Bell's relationships providing an experimental setup to solve the EPR paradox. In this communication is proposed an alternative reading of this history, showing that modern experiments based on correlations between light polarization significantly deviate from the original spirit of the EPR paper. It is concluded that current experimental violations of Bell's inequalities cannot be considered as an ultimate proof of the completeness of quantum physics models.

8832-55, Session 11

Observation of bosonic coalescence and fermionic anti-coalescence with indistinguishable photons

Guillaume Adenier, Arnt Inge Vistnes, Univ. I Oslo (Norway)

The symmetrization postulate asserts that the state of particular species of particles can only be of one permutation symmetry type: symmetric for bosons and antisymmetric for fermions. We report some experimental results showing that pairs of photons indistinguishable by all degrees of freedom can exhibit not only a bosonic behavior, as expected for photons, but also a surprisingly sharp fermionic behavior under specific conditions.

8832-57, Session 12

Nonclassical effects in two-photon interference experiments: an event-by-event simulation

Kristel F. Michielsen, Fengping Jin, Forschungszentrum Jülich GmbH (Germany); Hans De Raedt, Univ. of Groningen (Netherlands)

It is shown that both the visibility $V = 1/2$ predicted for two-photon interference experiments with two independent sources and the visibility $V = 1$ predicted for two-photon interference experiments with a parametric down-conversion source can be explained in terms of a locally causal, adaptive, corpuscular, classical (non-Hamiltonian) dynamical system. Hence, there is no need to invoke quantum theory to explain the so-called nonclassical effects in the interference of signal and idler photons in parametric down conversion and a revision of the commonly accepted criterion of the nonclassical nature of light is called for.

8832-58, Session 12

Event-by-event simulation of experiments to create entanglement and violate Bell inequalities

Kristel F. Michielsen, Fengping Jin, Forschungszentrum Jülich GmbH (Germany); Hans De Raedt, Univ. of Groningen (Netherlands)

We discuss a discrete-event simulation approach that does not require the knowledge of the solution of a wave equation of the whole system, yet reproduces the statistical distributions of Maxwell's theory and quantum theory by generating detection events one-by-one.

This event-based approach, which gives a unified cause-and-effect description of quantum optics experiments such as single-photon Mach-Zehnder interferometer, Wheeler's delayed choice, photon tunneling, quantum eraser, double-slit, Einstein-Podolsky-Rosen-Bohm and Hanbury Brown-Twiss experiments [1], has recently been extended to neutron interferometry experiments.

We illustrate the approach by application to single-photon Einstein-Podolsky-Rosen-Bohm experiments [2] and single-neutron interferometry experiments that violate a Bell inequality [3].

Einstein-Podolsky-Rosen-Bohm laboratory experiments: data analysis and simulation

Hans De Raedt, Univ. of Groningen (Netherlands); Kristel F. Michielsen, Fengping Jin, Forschungszentrum Jülich GmbH (Germany)

It is shown that data produced by state-of-the-art Einstein-Podolsky-Rosen-Bohm (EPRB) experiments does not support the hypothesis that the statistics of this data is described by quantum theory, this in spite of the fact that the data violates Bell inequalities. Furthermore, it is shown that an event-based simulation model, providing a cause-and-effect description of real EPRB experiments at a level of detail which is not covered by quantum theory, reproduces the results of quantum theory of this thought experiment, indicating that there is no fundamental obstacle for laboratory EPRB experiments to produce data which is in concert with the quantum theoretical description.

8832-60, Session 12

A rational explanation of wave-particle duality of light *(Invited Paper)*

Sergey A. Rashkovskiy, A. Ishlinsky Institute for Problems in Mechanics (Russian Federation)

The wave-particle duality is a fundamental property of the nature. At the same time, it is one of the greatest mysteries of modern physics. This gave rise to a whole direction in quantum physics - the interpretation of quantum mechanics. The Wiener experiments demonstrating the wave-particle duality of light are discussed. It is shown that almost all interpretations of quantum mechanics allow explaining the double-slit experiments, but are powerless to explain the Wiener experiments. The reason of the paradox, associated with the wave-particle duality is analyzed. The quantum theory consists of two independent parts: (i) the dynamic equations describing the behavior of a quantum object (for example, the Schrodinger or Maxwell equations), and (ii) the Born's rule, the relation between the wave function and the probability of finding the particle at a given point. It is shown that precisely the Born's rule results in paradox in explaining the wave-particle duality. In order to eliminate this paradox, we propose a new rational interpretation of the wave-particle duality and associated new rule, connecting the corpuscular and wave properties of quantum objects. It is shown that this new rational interpretation of the wave-particle duality allows using the classic images of particle and wave in explaining the quantum mechanical and optical phenomena, does not result in paradox in explaining the double-slit experiments and Wiener experiments, and does not contradict to the modern quantum mechanical concepts. It is shown that the Born's rule follows immediately from proposed new rules as an approximation.

John Caulfield at POC: from holographic components to small system integration *(Invited Paper)*

Tomasz P. Jannson, Andrew A. Kostrzewskik, Thomas C. Forrester, Ranjit D. Pradhan, Wenjian Wang, Physical Optics Corp. (United States)

With his exceptional scientific expertise, John Caulfield was involved at POC from its inception (1985) to present. This paper reviews his recent involvement at POC (2006-2012) which includes both optical and less known non-optical scientific and engineering areas.

8833-3, Session 1

Evolution of our understanding of the human visual system and its impact on our intelligent instruments *(Invited Paper)*

Marija Strojnik Scholl, Gonzalo Páez, Ctr. de Investigaciones en Óptica, A.C. (Mexico)

Humans succeeded in empowering machines to respond to stimulus with autonomous action, thus creating intelligent action in very specific environments. Semiconductor-incorporating electronic computers proved amenable to the implementation of procedural rules. Upon consultation with the relevant knowledge bases, machines became intelligent arriving autonomously to a decision to take action on the basis of stimulus.

We reflect on productive cross-fertilization between neurological knowledge and machine vision research. We comment on the development of our understanding about their action circuits activated by the photon stimulus, during Prof. John Caulfield productive life (past 50 years).

8833-4, Session 1

Forward and backward propagation in positive and negative index materials *(Invited Paper)*

Joseph W. Goodman, Stanford Univ. (United States)

In positive index materials, it is convenient to represent forward propagation of monochromatic light by a transfer function in spatial frequency space. Backward propagation can be used as a tool to discover what object gave rise to a field some distance away, using an appropriate inverse transfer function, provided interferometry is used to measure that distant complex field. However, detector noise limits the ability to successfully back propagate weak high frequency components and evanescent components. Consider a sequence of a positive index material sandwiched with a negative index material and followed by a positive index material. In the negative index material, forward propagation becomes identical with back propagation in the positive index material, but without the introduction of detector noise in between. Rather, detector noise is introduced when the image is detected in the final positive index medium. Attenuation associated with the negative index material is the limiting factor in this case.

8833-5, Session 1

3D measurement using circular gratings *(Invited Paper)*

Kevin G. Harding, Dan Gray, GE Global Research (United States)

3D measurement using methods of structured light are well known in the industry. Most such systems use some variation of straight lines, either as simple lines or with some form of encoding. This geometry assumes the lines will be projected from one side and viewed from another to generate the profile information. But what about applications where a wide triangulation angle may not be practical, particularly at longer standoff distances. This paper explores the use of circular grating patterns projected from a center point to achieve 3D information. Originally suggested by John Caulfield around 1990, the method had some interesting potential, particularly if combined with alternate means of measurement from traditional triangulation including depth from focus methods. The possible advantages of a central reference point in the projected pattern may offer some different capabilities not as easily attained with a linear grating pattern. This paper will explore the pros and cons of the method and present some examples of possible applications.

8833-6, Session 1

Tunable focalizers: axicons, lenses, and axilenses *(Invited Paper)*

Jorge Ojeda-Castaneda, Sergio Ledesma, Cristina M. Gomez-Sarabia, Univ. de Guanajuato (Mexico)

We explore the use of two angular varying phase masks, which work as a pair, for implementing tunable focalizers. We show that the proposed optical device is useful for implementing controllable, rotationally symmetric phase delays. The novel pair is applied for synthesizing tunable versions of axicons /1/, lenses /2/ and axilenses /3/. Furthermore, we note that the proposed optical device is also useful for generating and controlling several wavefront aberrations /4, 5/.

Multi-wavelength heterodyne holography and interferometry *(Invited Paper)*

Toyohiko Yatagai, Utsunomiya Univ. (Japan)

A new high-speed technique in digital holography is proposed, in which a phase-shifting algorithm utilizing the optical heterodyning effect and a high-speed CMOS camera are employed. In many phase-shifting algorithms, the phase distribution of the object is calculated by using a few reference phases with equal phase difference. In our proposed method, the arbitrary shift, including linear continuous and random phase, is introduced. The resultant phase difference between the object and the reference beams by vibrating an optical system can also be regarded as the phase-shifting introduced by optical heterodyning. The

phase distribution of the object is calculated by Fourier transforming the time-depending interference fringe data. If the reference phase shift is equally introduced to all the data points in the interference fringe image, the phase distribution at the peak frequency component in the Fourier spectrum gives the phase distribution of the object. Since a few hundred or more images were required in this method, a monochromatic CMOS camera with a high frame rate was used.

The principle of heterodyning technique is described. Then, the use of two wavelength in heterodyne phase-shifting holography and interferometry using a monochromatic image sensor is presented to perform surface shape measurement of the object. For color imaging and 3-D display, a three wavelength technique in which three color lasers are used at a same time is developed. Finally, a wide band light source is introduced to heterodyne phase-shifting holography. Its applications to wide range surface profiling and color imaging is discussed.

Autonomous tracking of designated persons in crowded scenes *(Invited Paper)*

Kaveh Heidary, R. Barry Johnson, Alabama A&M Univ. (United States)

This paper develops an algorithm for autonomous tracking of a person (target) within a crowded and temporally dynamic scene using a multispectral imaging system. The camera is stationary, the field of view is static, and the sensor pixel footprint is on the order of one inch. The operator designates the target to be tracked by selecting a single target-pixel in the first image frame, preferably close to the center of mass of the observable portion of the target in that particular frame. Following the initial designation, the algorithm tracks the target in real-time autonomously with minimal latency even when target obscuration occurs. The tracking algorithm is based on a novel temporally adaptive spatial-spectral filter bank used to detect target presence or lack thereof in the field-of-regard of the video frame produced by the multispectral cameras. The theory of the temporally adaptive spatial-spectral filter is based on an extension of our earlier work on the generalized matched filter bank (GMFB).

8833-9, Session 2

Surface multiplasmonics for optical sensing *(Invited Paper)*

Stephen E. Swiontek, Drew P. Pulsifer, Akhlesh Lakhtakia, The Pennsylvania State Univ. (United States)

Surface-plasmon-polariton (SPP) waves are electromagnetic surface waves commonly used for optical sensing of chemical and biochemical analytes in a host of research settings. These SPP waves are guided by the interface of a metal and a dielectric material. The SPP wave is the resultant of interactions of free electrons in the metal and polaritons in the dielectric which form quasiparticles called plasmon-polaritons that propagate along that interface.

Commonly used prism-coupled optical sensors based on SPP-wave phenomenon can only sense one analyte, because only one SPP-wave can be guided along the interface of a metal and a partnering homogeneous dielectric material. It has been theoretically and experimentally demonstrated that multiple SPP-wave modes can be launched at that interface provided the partnering dielectric material is periodically nonhomogeneous normal to the interface. An example is a chiral sculptured thin film (CSTF). If the porous regions of the CSTF are infiltrated with a fluid, the angular locations of the SPP-wave modes shift and the device behaves like an optical sensor.

Therefore, a 30-nm-thick aluminum film was deposited onto an SF-11 glass substrate, followed by a partnering lanthanum-fluoride CSTF which was three- or four-periods thick with a pitch of 400 nm. The sample was then affixed to an SF-11 right-angle prism and the reflected intensities of a p-polarized plane wave at different angles of incidence were recorded. Multiple SPP-wave modes shifted when the void regions of the CSTF were infiltrated with a fluid, thus demonstrating a surface-multiplasmonics sensor.

8833-10, Session 2

Uses of spatial light modulators for colour optical processing *(Invited Paper)*

Juan Campos, Univ. Autònoma de Barcelona (Spain); Ignacio Moreno, Univ. Miguel Hernández de Elche (Spain); Josep Nicolas, CELLS - ALBA (Spain); María J. Yzuel, Univ. Autònoma de Barcelona (Spain)

In this work we review the use of spatial light modulators (SLMs) for optical processing applications involving colour management. These applications include their use in optical correlator architectures to perform correlation based pattern recognition. We include pioneering results in collaboration with H. J. Caulfield where colour information was introduced onto the optical correlator by means of gratings with different orientation, frequency and amplitude. This allowed the application to colored scenes of the techniques of coherent optical correlation. The application of SLMs in this subject allowed the realization of optical processing with real time programmable operations, and the realization of efficient phase-only Fourier transform matched filtering.

Nowadays the use of SLMs to manage colour optical processing extends to applications including colour digital holography, multispectral and hyperspectral filtering and imaging, polarimetric sensing in different spectral bands, or the spectral control required for pulse shaping. Here we analyze techniques for the spectral characterization of liquid crystal SLMs. We analyze the spectral characteristics of the optical modulation properties of liquid crystal SLMs. We also review some of the advances carried out in the last fifteen years in their use for some of the above-mentioned applications.

8833-11, Session 3

Compressive imaging: a new field benefiting of classical optical signal processing techniques *(Invited Paper)*

Adrian Stern, Ben-Gurion Univ. of the Negev (Israel)

In a paper published 15 year ago ["Perspectives in optical computing," Computer , 31(2), 22-25, 1998] Prof. Caulfield shared his perspective on the role of optics in information processing. In a retrospective view on optical computing and optical signal processing, based on his thirty years' experience in the field, he pointed on the misdirected effort towards replacing non-optical computers with all-optical ones. Rather than supplanting computers electronics he suggested that optics can be of great benefit for certain other information processing tasks. Among such tasks he pointed on inherent optical applications and 2D array mapping. Here we show that these tasks can be used for a somehow related field; computational imaging. Particularly, we will refer to compressive imaging, which is a field that seeks to implement the theory of compressive sensing (CS) for optical imaging. Compressive sensing is considered a huge breakthrough in signal acquisition. CS theory offers a mathematical framework which allows us to reconstruct the data from substantially less measurements that imposed by the Shannon-Nyquist theorem. CS theory requires that the signals to be measured have a sparse representation in some mathematical domain, a property that all human-intelligible images have, and using a prescribed sensing mechanism. We show that the required sensing operators can be readily implemented with techniques developed for optical signal processing, such as optical Fourier filters, optical matrix vector multipliers, and anamorphic processors.

8833-12, Session 3

Comparative analysis between two different glitter functions for deducing statistical properties of sea surface slopes *(Invited Paper)*

José Luis Poom-Medina Sr., Univ. de Sonora (Mexico); Josué Álvarez-Borrego, Ctr. de Investigación Científica y de Educación Superior de Ensenada (Mexico); Angel Coronel-Beltran, Univ. de Sonora (Mexico); Beatriz Martín-Atienza, Univ. Autónoma de Baja California (Mexico)

The description and interpretation of ocean waves requires statistical techniques due to the nature of the sea surface considered as a continuous random process. This dynamical system is a stationary stochastic process of Gaussian type as a first approximation. One important feature of sea surface is the mean and the variance of the waves. These parameters can be found when sea waves are studied with pressure sensors, but is so expensive. In this paper a Gaussian glitter function is used as a first approximation to a real glitter function and some statistical properties like means and variances are calculated in order to find a statistical relationships between the glitter pattern of the sea surface and the sea surface slopes. In this work, the analytical solutions found for the mean and variances are different mathematically using Gaussian glitter function instead rect function, but both results are very similar, for instance they are qualitatively identical but quantitatively different as shown in the graphs obtained with our new analytical equations.

We can interpret from the graphics obtained from both functions for modeling the variance of the intensities of the images as a function of the variance slope have the same statistical behavior. In our new graphs we can observe that the variance of the intensities of the images have smaller values than those reported by other authors. These results suggest that when the Gaussian glitter function was used causes smaller values in the frequencies that contain the sea surface wave power spectrum.

8833-14, Session 4

Simultaneous and similar ideas with John Caulfield *(Invited Paper)*

W. Thomas Cathey Jr., Univ. of Colorado at Boulder (United States)

John and I were both interested in holography and ways to obtain the reference wave that is needed to interfere with the wave coming from the object. I was working for Autonetics, in Anaheim, Califonia. The company was more interested in patents than papers, so I filed a patent on an idea that I had for obtaining a mutually coherent reference wave from the object wave. At about the same time, John submitted a paper with almost exactly the same title. The topic that we jointly worked on was related to ways to modulate the wavefront of a coherent wave, using the information from an image formed with incoherent light.

8833-15, Session 4

Hijacking of the 'holographic principle' by cosmologists *(Invited Paper)*

Chandrasekhar Roychoudhuri, Univ. of Connecticut (United States)

The Ne-atoms in a He-Ne discharge tube and light emitting atoms in different galaxies are QM law-abiding entities. Atoms participating in spontaneous and stimulated emissions must release and perceive photon wave packets as having the same QM-allowed frequency , even when they are statistically executing Maxwellian velocity distribution. Thus, a spontaneously emitted energy packet from a moving Ne-atom will evolve as a photon wave packet carrying a Doppler shifted frequency . But an excited Ne-atom would be able to respond to this Doppler shifted frequency as only if it is executing the same vectorial velocity as the original emitter of this wave packet. It has to nullify the physical Doppler shift of the wave packet by traveling in the same direction with same velocity. All other excited Ne-atoms ignore this stimulating wave packet as they perceive the carrier frequency as different shades of , but not as .This is at the root of "inhomogeneously broadened" Ne-gain medium, which gives rise to multiple longitudinal modes in He-Ne lasers. Thus, optical Doppler shift is a function of both the velocities of source and the detector, instead of the relative velocity alone. Thus distance dependent Cosmological Red Shift should not be explained as due to Doppler effect given by only the relative velocity between any pair of galaxies. We propose a distance dependent dissipative effect, implying that the universe could be "stationary".

8833-16, Session 4

Holography: origin, development, and beyond *(Invited Paper)*

Francis T. Yu, The Pennsylvania State Univ. (United States)

I shall discuss the origin of wave front reconstruction, which could have been happen as the development of the Magic Mirror or See-Through Mirror in ancient China. Although the concept of wave front reconstruction was first demonstrated by Dennis Gabor in 1948, but a rather similar image sampling was due to Ives in 1906 for color imaging. Nonetheless there are basically two types of wave front reconstructions that have been developed, namely Leith's transmission-type holography and Dennisyuk's reflection-type holography. However Leith's transmission-type hologram is profoundly related to Ives sampling photography, and Nennisyuk's reflection-type hologram is in fact, as I see it, the legacy of Lippmann's color photography. Nevertheless the successful rediscovery of holography must be due to the development of a strong coherent source, known as the laser. Yet the original purpose for the development of holography was mainly to reproduce a truly three-dimensional imagery, but it has a much deeper application far beyond the legacy, as I shall be shown some of them in this talk.

8833-17, Session 4

A theoretical comparison of Fresnel based digital holography and phase retrieval from the transport of intensity equation. *(Invited Paper)*

Damien P. Kelly, Technische Univ. Ilmenau (Germany); Lysann Megel, Thomas Meinecke, Technische Univ Ilmenau (Germany); Stefan Sinzinger, Technische Univ. Ilmenau (Germany)

Holography is now a widely established imaging and inspection tool, that allows the amplitude and phase of an optical wavefield to be directly measured. It continually finds new applications in metrology and biology. Originally holograms were recorded on photographic plates, which needed to be developed before the hologram could first be inspected. In modern holography, these analog recording media have been replaced, by CCD and CMOS digital arrays. These digital arrays differ in several regards from earlier recording media and have an important influence on the properties of the reconstructed holograms. Several of these different properties are explored in this conference paper and contrasted with what would be expected for analog recording media. While measuring the amplitude and phase of an optical wavefield is important, often one wishes to control the optical distribution at a given plane. This can be achieved using diffractive structures that have been designed carefully using iterative Fourier transform based algorithms. Here we review some of our recent work in this area.

8833-18, Session 4

Color sensing under microwaves *(Invited Paper)*

Debesh Choudhury, Neotia Institute of Technology, Management and Science (India)

Color of an object is a perception under the illuminating light source. The wavelength of the illuminating source and the detector 'eye' play vital roles in color perception. Equally important is the color object itself. Inspired by recent results of artificial color due to Caulfield [1], we present a methodology for sensing visual colors under microwaves. We try intuitive experiments using a Gunn diode as the microwave source and a horn antenna to sense the transmitted microwaves through the objects. The objects used are glasses filled with water of different colors. The dielectric constant of water changes due to the different colors. The transmitted microwave power through the objects is detected which is proportional to the color information of the liquid objects. The sensed color signals are enhanced using Caulfield-Maloney normalization [2]. Preliminary results validate the feasibility of discriminating otherwise visual colors under microwave illumination. Caulfield's presumptions worked nicely in simple microwave experiments [3]. This research finding indeed paves down a way for extending artificial color in the microwave bands.

8833-19, Session 4

Object detection by optical correlator and intelligence: recognition surveillance systems *(Invited Paper)*

Yunlong Sheng, Univ. Laval (Canada)

We report our recent work on robust object detection in high-resolution aerial imagery in urban environment for Intelligence, Surveillance and Recognition (ISR) missions. Our approaches used the simple linear iterative clustering combining regional (color) and edge (space distance) information to form the superpixels. The irregularity in size and shape of the superpixels measured with the Hausdorff distance served to determine the salient regions in the very large-scale aerial images. Then the car detection was performed with the component-based approach. The superpixels were merged statistically to regions, which were described by the radiometric, geometrical moments and shape features, and detected using the Support Vector Machine (SVM). The cast shadow are detected and removed by a radiometry based tricolor attenuation model. Object parts detection is less sensitive to occlusion, rotation, and scale, view angle and illumination changes than detecting the object as whole. The car parts were combined to cars according to unique spatial relations with a deformable object-model. On the other hand, we use the invariant scale invariant feature transform features to describe superpixels as belong to vehicle or non-vehicle classes by the SVM. The classified superpixels are clustered to the detected cars by unsupervised Affine Propagation clustering. From our own experience we trace how the excellent historic ideas by pioneers as H. J. Caulfield in early days for optical pattern recognition, such as the composite matched filters, have been inherited transformed and reinvented in the new approaches to achieve tremendous research progress.

8833-20, Session 4

Energy efficient computing exploiting the properties of light *(Invited Paper)*

Joseph Shamir, Technion-Israel Institute of Technology (Israel)

Energy dissipation in computing stems from fundamental theoretical considerations as well as from the physical nature of electronic processes. A theoretical lower limit of energy dissipation is rooted in the operation of traditional Boolean logic gates that have two inputs and only one output. As a consequence, information is lost on the way and the input cannot be reconstructed from the output. We say that this operation is irreversible and, from entropy considerations, the loss of information is also associated with dissipation of energy. Electronic computers also suffer an additional source of energy dissipation caused by the motion of electrons involved for information transmission and processing. To move electrons electric fields must be applied and energy dissipating currents must be induced.

To achieve a significant reduction in the loss of energy both sources of energy dissipation can be addressed. The lower theoretical limit of energy dissipation can be mitigated by replacing arrays of traditional Boolean logic gates by other methods of implementing logic operations. In particular, a slight modification of the concept of computing allows the incorporation of fundamentally lossless optical processes as part of the computing operation. Moreover, unlike electrons, the propagation of light does not require energy consumption except for the light generation and its final detection. One possible implementation is based on directed logic networks exploiting reversible optical logic gate arrays.

8833-21, Session 4

The amazing evolutionary dynamics of non-linear optical systems with feedback *(Invited Paper)*

Leonid P. Yaroslavsky, Tel Aviv Univ. (Israel)

Optical systems with feedback are, generally, non-linear dynamic systems. As such, they exhibit evolutionary behavior. In the paper we present results of experimental investigation of evolutionary behavior of several models of such systems. The models are modifications of the famous mathematical "Game of Life". The modifications are two-fold: "Game of Life" rules are made stochastic and mutual influence of cells is made spatially non-uniform.

New phenomena in the evolutionary behavior of the models are reported. Among them: Optical systems with feedback are, generally, non-linear dynamic systems. As such, they exhibit evolutionary behavior. In the paper we present results of experimental investigation of evolutionary behavior of several models of such systems. The models are modifications of the famous mathematical "Game of Life". The modifications are two-fold: "Game of Life" rules are made stochastic and mutual influence of cells is made spatially non-uniform.

New phenomena in the evolutionary behavior of the models are reported. Among them: (i) "Ordering of chaos". Formation from seed patterns of stable ordered maze-like patterns with chaotic "dislocations" that resemble natural patterns, which one can frequently find in the nature, such as finger prints, zebra skin, see shell, magnetic domain structure patterns and alike. These patterns and their fragments exhibit remarkable capability of unlimited growth.

(ii) "Self-regulated growth". Growth of "chaotic live" formations into "communities" bounded, depending on the model, by a square or hexagon, until they reach certain critical size, after which the growth stops.

(iii) "Life in a bounded space" and "Coherent shrinkage". After the growth stops, square or hexagon bounded "communities" stabilize in their size for a while remaining active within their bounds and demonstrating a kind of "life in a bounded space", and then, after certain number of iteration steps began shrinkage and finally degenerate into one of stable or oscillating patterns preserving in this process their bounding shape until the very end.

Fast implementation of Oliker's ellipses technology to build free form reflector

Simon Magarill, Synopsys, Inc. (United States)

The field of illumination optics has a number of applications where using freeform reflective surface to create a required light distribution can be beneficial. Oliker's concept of combining elliptical surfaces is one foundation for forming a reflector that can create an arbitrary illuminance distribution. An approach that leads to a fast implementation of this concept is presented and demonstrated. It is based on analytical computation of a 3D cloud of points in order to map the reflector shape that provides the required flux distribution. The flux delivered to chosen zones across the target can be calculated based on its location and on a number of associated cloud points. The method includes the optimization of individual ellipses parameters to achieve the required flux distribution without raytracing through the reflector geometry. Such strictly analytical optimization is much faster than building reflector geometry and performing a raytrace at each step of the optimization. The 3D cloud of points that is generated from the optimization can be used as an input to a standard SolidWorks feature that is then used to build a loft surface. This surface consists of adjacent elliptical facets and would be smoothed as a final step to maintain continuous irradiance across the target. Secondary operation to smooth surface profile between elliptical facets is discussed.

Mapping algorithm for freeform construction using non-ideal light sources

Chen Li, Dirk Michaelis, Peter Schreiber, Andreas Bräuer, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany)

Using conventional mapping algorithms for the construction of illumination freeforms arbitrary target pattern can be obtained for idealized sources, e.g. collimated light or point sources [1,2,3]. Each freeform surface element generates an image point at the target. For sources with a pronounced extension and ray divergence, e.g. an LED with a small source-freeform-distance, the image points are blurred. These individual light distributions of each freeform element are taken into account in a mapping algorithm [4]. To this end the method of steepest decent including special weighting and smoothing procedures are used to adapt the mapping goal. The corresponding linear optimization matrix is gained by conventional raytracing. Nontrivial source geometries, like LED-irregularities due to bonding or source fine structures, and a complex ray divergence behavior can be easily considered. Additionally, Fresnel losses and even stray light are taken into account.

The algorithm is applied to several design examples. A homogeneous LED-illumination of a tilted or bended target and the generation of a structured target pattern are discussed. Finally, freeform designs for clusters of LED-sources are presented.

8834-4, Session 1

Design of light concentrators for Cherenkov telescope observatories

François F. Hénault, Pierre-olivier Pettrucci, Lab. d'Astrophysique de l'Observatoire de Grenoble (France); Bruno Khélifi, Laboratoire Leprince-Ringuet, Ecole Polytechnique (France); Jürgen Knödlseder, Institut de Recherche en Astrophysique et Planétologie (France); Michael Punch, Université Paris 7 Denis Diderot (France)

The Cherenkov Telescope Array (CTA) will be the largest cosmic gamma ray detector ever built in the world. It will be installed at two different sites in the North and South hemispheres and should be operational for a minimal period of 30 years. In order to cover the desired energy range, the CTA is composed of typically 50-100 collecting telescopes of various sizes (from 6 to 24-m diameters). Each of them is equipped with a focal plane consisting of 1500 or 2000 Photomultipliers (PM) equipped with light concentrating optics, whose double function is to maximize the amount of energy collected by the telescope, and to block any stray light originating from the terrestrial environment. Two different optical solutions have been designed, respectively based on a CPC (i.e. a Winston Cone concentrator), and on a purely dioptric concentrating lens. In this communication are described the technical specifications, optical designs and performances of the different solutions envisioned for all those light concentrators. The current status of their prototyping activities is also given.

8834-5, Session 1

Intergrating refractive media into nonimaging designs: a self-consistent approach

Lun Jiang, Roland Winston, Univ. of California, Merced (United States)

The concept of skew invariant in nonimaging optics is applied to static symmetry-breaking solar collectors computationally by using genetic algorithm and Monte Carlo ray-tracing to optimize the annual energy yield of the collectors. The simulation result shows that the concentrator can achieve an optimized concentration with rejecting minimum solar radiation, which increases the efficiency and annual yield of the collectors. Furthermore, the results are compared with both the theoretical limit and the experimental data from translational symmetrical compound parabolic solar collectors.

8834-6, Session 1

Angular restriction of photon emission for ultra-efficient photovoltaics

Avi Braun, Eugene A. Katz, Daniel Feuermann, Ben-Gurion Univ. of the Negev (Israel); Brendan M. Kayes, Alta Devices, Inc. (United States); Jeffrey Gordon, Ben-Gurion Univ. of the Negev (Israel)

We present experimental evidence of enhancing the performance of ultra-efficient solar cells by external recycling of photon emission – based on the strategy of increasing open-circuit voltage by reducing radiative recombination. It is equivalent to restricting the angular range of photon emission, and can only be effective in solar cells with high external luminescent efficiency. This has precluded the enhancement from being observable in today's photovoltaic technologies. However, it is attainable with the latest generation of champion single-junction one-sun thin-film GaAs cells. The measurements are understandable in terms of basic photovoltaic thermodynamics.

8834-7, Session 2

The intersection of photonics and nonimaging optics in luminescent solar concentration *(Invited Paper)*

Noel C. Giebink, The Pennsylvania State Univ. (United States)

Optical concentration is a powerful and near-term strategy to lower the cost of electricity produced from established solar cell technologies because it reduces the cell area needed to generate a given amount of power. Whereas passive geometric optical concentrators are invariably bound by the sine limit, luminescent solar concentrators (LSCs) can in principle achieve high concentration ratio (>100x) without tracking the Sun. These devices traditionally consist of a transparent slab embedded with a chromophore that absorbs sunlight and actively re-emits it back into the slab, where it is trapped by total internal reflection and absorbed by photovoltaic cells attached to the edges. Despite their promise, however, practical LSCs have reached only a fraction of their theoretical potential, limiting their utility to date.

We are exploring a new opportunity to improve LSC performance by photonically controlling their spontaneous emission pattern and leveraging the increased directionality together with nonimaging optics to boost output intensity. Here, we discuss initial results based on the use of a simple thin-film bilayer that produces sharply directed conical emission and show that incorporating it on macroscopic freeform waveguides results in optical pseudo-potentials that act like in-plane graded index variations, channeling the flow of light and creating high intensity 'hot spots' at particular locations within the LSC. These results point toward an opportunity to design a new class of 'distributed' nonimaging waveguide surfaces that operate over the course of many bounces to optimally transform low etendúe luminescence for maximum geometric concentration.

8834-8, Session 2

Modeling light propagation in semiconductor-based luminescent solar concentrators

Derya Sahin, Boaz Ilan, Univ. of California, Merced (United States)

This research is focused on modeling light propagation in luminescent solar concentrators. We show the techniques that can be practical to use in the applications in the research areas of involving radiation and transport problems, specifically in solar science. We use two different approaches: radiative transport theory and Monte Carlo simulations for designing effective luminescent solar concentrators (LSCs). Our main goal is to inform the synthesis efforts of the optimal design parameters and obtain the results which can be used to develop LSCs based on semiconductor anisotropic nanorods.

Monte-Carlo (MC) simulations for photon transport have been commonly used tool to compute the performance metrics of LSCs. The optimal design parameters such as the optimal particle concentration, the optimal LSC size can be found by MC simulations. However, the convergence rate of MC simulations is slow. The overall computational time depends on the number of photons and the area of the reabsorption cross-section of the particles' spectra. Therefore, we seek to find an alternative method to model the light propagation in LSCs We study physical, analytical and computational modeling of the absorption and luminescence of light within the framework of radiative transport theory. This study highlights the role of radiative transport theory in modeling light propagation in luminescent media such as LSCs.

8834-9, Session 3

New Fresnel-Köhler optical design: 9-fold photovoltaics concentrator

João Mendes-Lopes, Univ. Politécnica de Madrid (Spain); Pablo Benítez, Light Prescriptions Innovators, LLC (United States); Pablo Zamora, Univ. Politécnica de Madrid (Spain); Juan C. Miñano, Light Prescriptions Innovators, LLC (United States)

Non-uniform irradiance patterns created by Concentrated Photovoltaics (CPV) systems over Multi-Junction Cells (MJC) can originate significant power losses. Furthermore, when chromatic aberrations between irradiance distributions over the different MJC sub-cells are significant, power losses increase considerably, especially when considering 4, 5 and 6 junction cells.

Recent advances in optical designs for CPV, namely Fresnel-Köhler (FK) technology, proven that a spectral balanced high irradiance uniformity is achievable for systems of 850-1000x and large acceptance angle. However, when aiming for larger concentrations, irradiance uniformity decreases for the same optical design family.

Interest on Silicon-on-Glass (SoG) lens has been growing due to the combination of mass production simplicity (injection molding) and high resistance to external factors. SoG lens refractive index is affected by thermal changes, affecting considerably spectral balance of irradiance distributions.

A new CPV optical design, with large acceptance angle and prepared to overcome these effects, is presented.

The 9-fold Fresnel-Köhler (FK-9) 1000x concentrator, with acceptance curve of 1.19º, is based on a SoG nine sectors Fresnel lens combined with a Secondary Optical Element with nine refractive free-form surfaces.

The advanced design was developed such that the performance features (concentration-acceptance products - CAP- between 0.62-0.66, depending on design parameters, excellent irradiance uniformity and spectral distribution) are kept when concentration increases to 2000x and when SoG lens refractive index is affected by thermal effects, revealing excellent tolerance to manufacturing and external factors.

This paper will show the main design features, along with realistic performance simulations considering all spectral characteristics of the elements involved.

8834-10, Session 3

FK concentrator outdoor measurements

Maikel Hernández, Juan F. Vilaplana, Light Prescriptions Innovators Europe, S. L. (Spain); Pablo Benítez, Univ. Politécnica de Madrid (Spain); Rubén Mohedano Arroyo, Light Prescriptions Innovators Europe, S. L. (Spain); Pablo Zamora, Juan C. Miñano, Univ. Politécnica de Madrid (Spain)

The FK is a two-stage optical concentrator for CPV, composed by a

Fresnel lens working as POE and a refractive element working as SOE. Both elements are divided into four sectors in order to perform Köhler integration, for uniform irradiance purposes. The FK concentrator has demonstrated that compares very well with other Fresnel-based concentrator optics, thanks to: (1) high optical efficiency; (2) large tolerance to tracking misalignment and manufacturing errors, thanks to a high CAP; (3) good irradiance uniformity and low chromatic dispersion on the cell surface.

In general, CPV optical concentrators provide non-ideal irradiance profile on the cell surface, presenting certain degree of non-uniformity and chromatic dispersion. Irradiances with uneven profiles and high chromatic dispersion lead to losses in fill-factor and module electrical efficiency. Additionally, when the module presents manufacturing or tracking misalignment, these negative effects are magnified entailing even larger module efficiency losses. The FK, a concentrator providing an even irradiance and low chromatic dispersion profile ensures high module electrical efficiency.

Recent on-sun measurements carried out on an FK mono-module prototype have already shown outstanding results, achieving electrical efficiencies over 34% (no AR coating applied on SOE) for the SoG case. Since in this case a first prototype of this design has been used, optical elements are not perfectly optimized yet. This fact brings enough room to predictably go over efficiency values of 35% (additionally applying an AR coating on the SOE) during the next months.

8834-11, Session 3

Optofluidic approaches to stationary tracking optical concentrator systems

Marco Stefancich, Adam Silvernail, Carlo Maragliano, Matteo Chiesa, Samuele Lilliu, Marcus Dahlem, Masdar Institute of Science & Technology (United Arab Emirates)

Etandue conservation limits static concentrators with high angular acceptance to low concentrations ratios [1]. Large light rejection angles are, however, an important limiting factor system efficiency [2], in flat panels and photovoltaic concentrator systems (CPV). Mechanical tracking allows the use of low acceptance systems by maintaining the system optical axis aligned with the sun direction. This raises, however, reliability issues [3] and prevents CPV from integration in urban and residential environments. Attempts to integrate the tracking in the panel have been made [4] but, besides some notable recent pioneering work [5], mechanical systems are still being used.

We propose to achieve a stationary tracking (non imaging) optical concentrator (STOC) by modifications of the system optics based on the manipulation of liquid interfaces or multiphase systems.

Optofluidic allows to dynamically modify the focal length of a liquid lens [6], the direction of a beam by electrowetting prisms [7] or the state of an optical switch [8]. A transition between reflective and transparent state can be associated to first order phase transition in multiphase systems. Each of these effects provides a possible approach to STOC.

We demonstrate, in a suitable multiphase system, a thermally induced transition between opaque and transparent state being used, together with a micro-optic lens system and a planar slab waveguide, in a novel concept of STOC.

The same results will be demonstrated by an electrophoresis based free space optical router, coupled with stationary lens and slab waveguide.

Theoretical framework, multiphysics modeling and preliminary experimental results will be discussed.

8834-12, Session 3

Wet-chemistry based selective coatings for concentrating solar power

Daniel Feuermann, Ben-Gurion Univ. of the Negev (Israel); Avi Kribus, Eran Maimon, Yuri Flitsanov, Tel Aviv Univ. (Israel); Oleg Skolnik, Ben-Gurion Univ. of the Negev (Israel); Camille Zwicker, Liraz Larush, Daniel Mandler, Shlomo Magdassi, The Hebrew Univ. of Jerusalem (Israel)

Spectrally selective coatings are common in low and medium temperature solar applications from solar water heating collectors to parabolic trough absorber tubes. They are also an essential element for high efficiency in higher temperature Concentrating Solar Power (CSP) systems. Selective coatings for CSP are usually prepared using advanced expensive methods such as sputtering and vapor deposition. In this work, coatings were prepared using low-cost sol-gel methods. Solutions of alumina/silica sol gel were prepared and then dispersed with black spinel pigments. The black dispersions were applied by spray/roll coating methods on stainless steel plates. The spectral emissivity of sample coatings was measured in the temperature range between room temperature and 500°C. Emissivity at wavelengths of 400–1700 nm was evaluated indirectly using multiple measurements of directional reflectivity. Emissivity at wavelengths 2,000–14,000 nm was measured directly using a broadband IR camera that acquires the radiation emitted from the sample, and a range of spectral filters. The longwave measurements were done at temperatures above 200°C in order to obtain sufficient emitted radiation signal. Emissivity measurement results for a range of coated samples will be presented, and the impact of coating thickness, pigment loading, and surface preparation will be discussed.

8834-13, Session 3

Spectrum-splitting module for illumination and photovoltaic operation using faceted daylighting structure

Shelby D. Vorndran, The Univ. of Arizona (United States); Michael Gordon, College of Optical Sciences, The Univ. of Arizona (United States); Juan M. Russo, Deming Zhang, Raymond K. Kostuk, Yuechen Wu, The Univ. of Arizona (United States)

A spectrum-splitting photovoltaic module using slanted reflection holograms is proposed. The module is intended for a 1-axis tracking rooftop installation. In addition to photovoltaic (PV) electricity generation, a portion of the spectrum is directed onto a secondary target for greenhouse illumination or interior daylighting. The module consists of alternating strips of PV cells and illumination regions. A reflection hologram with varying slant angle placed directly above the PV cell splits the spectrum by diffracting a spectral band at an angle greater than the critical angle of the substrate. This light makes one total internal reflection (TIR) before reaching an illumination region. To distribute the diffracted light into the building, a custom-shaped daylighting structure is matched to the incoming light's angular range, allowing escape from TIR and entrance into the building. The hologram and illumination structure are designed for maximum irradiance uniformity and spectral uniformity.

Raytracing software will be used to model the distribution of spectral irradiance upon the PV cell area and building interior. The system will also be modeled under various atmospheric conditions from direct to diffuse. Several ratios of PV to illumination area are evaluated, and tracking tolerance of the system is discussed. Losses in the module will be addressed, and the final design will be optimized for maximum optical efficiency.

8834-14, Session 4

Gradient-index lens design with quasi-conformal transformation optics for energy concentration *(Invited Paper)*

Douglas H. Werner, Jeremiah P. Turpin, Donovan E. Brocker, Xiande Wang, The Pennsylvania State Univ. (United States); Zhi Hao Jiang, The Pennsylvania State University (United States); Pingjuan L. Werner, The Pennsylvania State Univ. (United States)

Transformation Optics (TO) has enabled new methodologies for the design and specification of gradient-index (GRIN) lenses for radio-frequency and optical applications by linking refractive index gradients to a mathematically equivalent change in geometry in another dimension. With the new mathematical design tools, there have been many interesting devices introduced in the literature, such as optical collimators and absorbers (optical “black holes”), GRIN couplers and bends for optical waveguides, and compressed or flattened collimating lenses for imaging and non-imaging applications. Many of the most interesting TO designs are not feasible for implementation, however, due to the complex anisotropic, inhomogeneous material parameters required by the full TO formulation. Instead, restricting the geometric transformations to be mathematically conformal or quasi-conformal (qTO) eliminates the anisotropic material requirements and allows implementation with an isotropic 2D or 3D GRIN profile, for which multiple fabrication methods exist in the RF and IR wavelength ranges and are in development for the complete optical spectrum. We present an overview of the usefulness of combining TO, qTO, and GRIN optics for energy concentration along with the associated design and analysis techniques.

Moving away from traditional lenses to GRIN and TO optics for which, in general, no analytical geometric optics or full-wave solution exists, involves the development of new design strategies for individual lenses and systems of lenses. We demonstrate results obtained using advanced, multivariate optimizations that are tightly coupled to a fast, advanced inhomogeneous ray tracing engine for electrically-large lenses, and to an efficient body-of-revolution solver for electrically-small cylindrically-symmetric lenses.

8834-15, Session 4

Design method for color-corrected layered spherical lenses

Narkis E. Shatz, John C. Bortz, SAIC (United States)

We consider the problem of designing imaging lenses consisting of thin, concentric, spherical annuli, each having a constant refractive index at a specified wavelength. For single-wavelength designs, we describe a recursive algorithm capable of generating the annular layer structure required to achieve arbitrarily low aberration levels, based on a specified structure of the outer layers. For the design of color-corrected lenses, we show how the single-wavelength design method can provide a parsimonious parametrization scheme that can be used in conjunction with a global optimization process to search for designs exhibiting minimal aberrations over the desired waveband of operation and that also satisfy design constraints.

Distribution Statement “A”: Approved for Public Release, Distribution Unlimited

8834-16, Session 4

Engineering metacrystals and flat optics with Huygens, Fermat, Bragg, and Fresnel laws *(Invited Paper)*

Zeno Gaburro, Univ. degli Studi di Trento (Italy)

Novel perspectives are introduced by combining classical concepts, starting from Bragg interference, with metamaterials. How about combining polarization properties of meta-atoms with translational symmetry? How can glide planes be exploited in spectroscopy and in optomechanics? What can be said about impedance? I will address these questions and others. The battle horse will be a structure that generalizes classical Snell and Fresnel laws, based on “phase discontinuities”. I will finally outline some future challenges and opportunities.

8834-17, Session 5

Free-space optics for reconfigurable card-to-card optical interconnects

Ke Wang, Ampalavanpillai T. Nirmalathas, Christina Lim, Efstratios S. Skafidas, The Univ. of Melbourne (Australia); Kamal E. Alameh, Edith Cowan Univ. (Australia)

We proposed and experimentally demonstrated a 3?20 Gb/s free-space based reconfigurable car-to-card optical interconnect architecture for data-centers and high-performance computing. The proposed system employed low-cost VCSEL array as the transmitter and was based on free-space optical signal transmission, where the beams can be dynamically steered to different cards by MEMS-based steering mirrors to realize flexibility and reconfigurability. Compared with other beam steering mechanisms, MEMS-based mirrors have the advantages of simple tuning principle through signal reflection and high tuning efficiency by proper coating. Micro-lens arrays were also utilized to collimate the optical beams at the transmitter side and for signal focusing at the receiver side. Small-size printed-circuit-board (PCB) based optical interconnect modules were designed and fabricated. These modules used 1?4 VCSEL arrays as light sources and the VCSELs had a 3-dB electrical bandwidth of ~9.6 GHz. To increase the bit rate, VCSELs were directly modulated with 4-level carrierless amplitude and phase (4-CAP) modulation format (2 b/s/Hz spectral efficiency). With 2 mW transmission power, 3?20 Gb/s interconnect was realized for up to 30 cm card-to-card horizontal distance with a bit-error-rate (BER) of ~10-6. The reconfigurability was also demonstrated on both port- and card- levels with three different channel configurations characterized. Furthermore, the receiver sensitivity (at the BER of 10-9) of proposed scheme was measured and when the card-to-card horizontal distance was 20 cm, the worst-case sensitivity was shown to be better than -11.10 dBm. When the horizontal distance increased, the sensitivity became slightly worse, mainly due to the inter-channel crosstalk.

8834-18, Session 5

Freeform TIR collimators for the removal of angular color variation in white LED spotlights

Corien Prins, Technische Univ. Eindhoven (Netherlands) and Philips Electronics Nederland B.V. (Netherlands); Christine Schneider, Teus W. Tukker, Philips Lighting B.V. (Netherlands); Jan ten Thije Boonkkamp, Technische Univ. Eindhoven (Netherlands); Wilbert L. IJzerman, Philips Research Nederland B.V. (Netherlands)

Angular color variation in white, phosphor-converted LEDs is an urgent

problem in lighting. The color variation is caused by the conversion of blue light into yellow light by the phosphor layer, and therefore inherent to phosphor-converted LEDs. Spotlights using such LEDs show undesirable, yellow rings in the beam. LEDs can be modified to reduce the color variation, but this increases their cost and reduces their luminous efficiency. A better solution is to modify the surface shape of the collimator. We developed an inverse method to design collimators that completely remove the color variation for point light sources without the need of facets, holographic foils or scattering surfaces. The design procedure consists of two steps: first we construct transfer functions for the light from the source to the target, such that in the far field we have the required intensity and the color variation is removed. This is done using measured chromaticity and intensity data of the LED. Subsequently, we calculate the free surfaces of a collimator using the generalized functional method developed by Bortz & Shatz. We performed numerical simulations with the resulting collimators in the ray tracing program LightTools. We discuss the method, and show results of numerical simulations, where we take both ideal point sources and realistic light sources into account.

8834-19, Session 5

Advances in aplanatic optics for illumination

Lun Jiang, Roland Winston, Univ. of California, Merced (United States)

In a previous SPIE conference1 we presented a development in aplanatic design that can be traced back to Galileo, Newton and Descartes. In this presentation we show a design improvement that makes this more efficient and more affordable2. We now go even further back in time to Hypatia of Alexandria (335-405AD) who was arguably one of the greatest mathematicians of the ancient world.

8834-20, Session 5

Estimation of the flux collected by conic reflector patches

Cristina Canavesi, Univ. of Rochester (United States); William J. Cassarly, Synopsys, Inc. (United States); Jannick P. Rolland, Univ. of Rochester (United States)

The Oliker supporting ellipsoids algorithm for freeform reflector design builds a reflector from sections of conics, each of which redirects the light from the point source to a discrete target point. The design process consists of iteratively adjusting the optimization variables that control the size and shape of the conics, and evaluating the flux for each target point, until the desired target illumination is met within a set tolerance. The estimation of the amount of flux directed to each target required at each iteration step is currently a main limitation to the computation speed of the supporting ellipsoids algorithm. The target evaluation method also drives the accuracy of the reflector solution obtained. A common approach for estimating the flux collected by the reflector patches is to use Monte Carlo ray tracing, and the choice of the number or rays traced is a trade off between accuracy and speed.

We explore an alternative flux estimation approach by calculating the intersections between neighboring conics to find the boundaries of each conic patch. Once the perimeter of each reflector patch is known, it is possible to calculate the solid angle subtended to estimate the flux collected.

8834-21, Session 6

Multiple luminous intensity distributions by using a single freeform optical element

Michael Berens, RWTH Aachen (Germany); Adrien Bruneton, RWTH Aachen (Germany); Axel Baeuerle, Fraunhofer-Institut für Lasertechnik (Germany) and RWTH Aachen (Germany); Martin Traub, Rolf Wester, Fraunhofer-Institut für Lasertechnik (Germany); Jochen Stollenwerk, RWTH Aachen (Germany) and Fraunhofer-Institut für Lasertechnik (Germany); Peter Loosen, RWTH Aachen (Germany) and Fraunhofer-Institut für Lasertechnik (Germany)

In many mass-production applications of lighting design, the cost of manufacturing as well as compact design plays a vital role in addition to the desired function. Thus, the integration of multiple functions within a single part can be of economic and ecological benefit.

Previously (“Irradiance tailoring with two-sided, Fresnel-type freeform optics,” in Proc. SPIE 8485), we presented a freeform lens design achieving a compact form factor by segmentation of the output surface. In this paper, we show that by segmenting the input surface, the integration of multiple lighting functions in a single lens is possible. This is demonstrated for an automotive application.

Using the method based on the Monge-Kantorovich theory of optimal mass transport, two optical surfaces (input and output surface) that create a single light distribution are designed. The resulting surfaces are then used as a basis for the introduction of smaller, secondary input surfaces that are designed to use the original output surface. This results in a compact lens design that integrates the functions of a fog lamp and a daytime running lamp by switching of multiple LED light sources.

Furthermore, the efficiency of the individual light paths resulting from the multiple light sources as well as the overall efficiency of the system is analyzed. Finally, the point of manufacturability is touched.

8834-22, Session 6

Novel multi-layer remote phosphor linear optics for solid state lighting

Charles Edwards, Intematix Corp. (United States)

As LEDs move into general lighting developing high efficiency, optically uniform linear light sources is critical. Presented is a new linear light emitting optic designed to work with blue LEDs (450-460nm). The first white appearance remote phosphor combines a high efficiency phosphor down-converter layer with an integrated secondary optic in a single component. The optic is produced using co-extrusion creating different optical layers in a single component. The outer layer can be an integrated hi efficacy diffuser or linear lens depending on the application.

Technical results that will be presented:

- Systems design and efficacy with multi-layer remote phosphor. At 4000K CCT system efficacy of 120lm/WDC can be achieved.

- First true white appearance remote phosphor. Remote phosphor is conventionally yellow. We explain how white appearance is achieved with an integrated, hi efficacy outer layer. Test results show equal performance to single layer, yellow remote phosphor.

- Light uniformity. White LEDs in linear typically have “hot spots” over each LED. Aggressive diffusers, up to 15% loss. Most LED use large T8 size (1” OD) to improve uniformity. We show how this new architecture achieves uniform light with smaller OD and no 2ndary diffuser. Uniformity achieved with 12mm spacing in a compact T5 (5/8”) form factor.

- CCT from 2700K-5000K and CRI of 70CRI to >95 are achievable with the relative performance of different CCTs and CRIs being presented.

8834-23, Session 6

Light trapping in LED’s

Melissa N. Ricketts, Roland Winston, Univ. of California, Merced (United States); Julius A. Muschaweck, OSRAM GmbH (Germany)

The impressive progress in LED technology that has made LED's more efficient (lumens/watt) than common light sources, has encouraged investigation of potential advantages for creating a pleasing and productive environment. The effect of spectrum and variability are being studied is a controlled experiment.

8834-24, Session 6

Design and optimization of fiber lenses in plastic optical fibers for indoor illumination

Daniel E. Ceballos-Herrera, Perla M. Viera-González, Guillermo E. Sánchez-Guerrero, Gustavo Cárdenas-Ortíz, Valentín Gusmán-Ramos, Arturo Castillo-Guzmán, Romeo Selvas-Aguilar, Univ. Autónoma de Nuevo León (Mexico)

We present a numerical analysis of different fiber termination shapes in order to study the maximum numerical aperture that can be obtained in end emitting plastic optical fibers with diameters around 10 mm. Our analysis includes the modeling of angle polished fibers, conical lensed fibers, and wedged fibers with different lengths, angles and curvatures respectively. The optimization of these parameters allows us to obtain a maximum possible angle which the light can be emitted at the plastic fiber end. These results contribute to minimize the use of fiber components in luminaire systems which can be based in solar concentrators coupled to plastic optical fibers, and consequently it allows us to reduce their installation cost. We also analyze the light distribution of the emitted light and the optical tolerances of the parameters above mentioned to evaluate the performance of the optimized fiber lens. In addition, the effect of using gratings inscribed on the fiber lens surface is also discussed, and we explain how it can improve not only the emitted angle of the transmitted light, but also the amount of solar light coupled to the optical fiber. These results are of great interest for the improvement and design of compact luminaire systems based in optimized plastic fiber lens for indoor illumination.

8834-25, Session PMon

Far-field condition for OLED light sources

Wentao Cai, Xianming Liu, Peng Zhang, Weimin Chen, Chongqing Univ. (China)

Nowadays, white organic light emitting diodes (OLED) as the predominant light sources of the future are attracting much attention especially in the indoor lighting, due to the advantages of flexible, large area lighting, color tunable and high CRI, etc. In order to describe the light distribution properties of the OLED sources, the intensity under different azimuth angles should be obtained firstly. However, the light intensity definition is only applicable to point sources because the solid angle's vertex should be a point. For a real point source, the shape of the radiation pattern is independent of distance. The intensity is inversely proportional to the square of the distance from the source, which known as inverse square law. A light source can be modeled as a point source only if the detector is placed far enough away from the source. It is necessary to know where the far-field begins since most of the lighting designs are based on the far-field optical characteristics. In this paper, we deduce the far-field conditions for OLED sources with different continuous luminous area. The relative far-field distances (RFFD) for OLEDs with round, rectangular, annular, hemispherical and semicylindrical shapes are calculated. The RFFDs for LED arrays with the same size and light distribution are also given for comparation. Results show that the RFFDs for OLEDs are smaller than that of LED arrays with the same sizes. The classical five times rule is not applicable for all OLEDs with different luminous area.

8834-26, Session PMon

Analysis of far-field distance of LED arrays based on an improved error calculation formula

Wentao Cai, Xianming Liu, Peng Zhang, Weimin Chen, Chongqing Univ. (China)

Most of the lighting designs are based on the far-field characteristics of light sources. In the far-field region, a surface source can be modeled as a directional point source. For a point source, the illuminance E and the measurement distance d should satisfy the inverse square law. A surface source can be considered as a point source if the similarity from using the inverse-square law is higher than 99%. However, the results of where the far-field begin may be quite different with different similarity calculation formulas. In this paper, we calculate and compare the relative far-field distances (RFFD) of LED arrays with several commonly used similarity calculation formulas, such as the normalized cross correlation (NCC), cosine of vectorial angle (COS), constrained Pearson correlation(CPC), spearman rank correlation (SRC) and root mean square (RMS) weighted by the maximum value of the intensity at infinity. Results show that the weighted RMS is the most reasonable equation to define the far-field distance calculation error. Moreover, we propose the summing value but not the maximum value of the intensity as the weighting coefficient to define the RMS error, which can minimize the influence of the light distribution pattern of the light source. Finnally, the RFFDs of LED arrays of radiation patterns of Lambertain, concentrated-type and batwing are given with the proposed weighted RMS as calculation error.

8834-27, Session PMon

Quantitative comparison of photometric quantities for road lighting between CIE and IESNA standards

Shi LingNa, Chongqing Univ. (China) and Chongqing Jiaotong Univ. (China); Weimin Chen, Xianming Liu, Wei Lai, Chongqing Univ. (China)

There are two standard systems quantitatively defining the photometric quantities for road lighting, which are released by CIE (International Commission on Illumination) and IESNA (Illuminating Engineering Society of North America). The criteria definitions include the average road surface luminance, overall road surface luminance uniformity and longitudinal road surface luminance uniformity and so on, which are defined differently in the two standards. There were some reports analyzing these differences qualitatively. However, the quantitative description on these differences between CIE and IESNA standards has not been reported.

In this paper, we analyze the differences between CIE and IESNA standards quantitatively. Firstly, the backgrounds of the two road lighting standards are introduced. Secondly, the definition and computing method about the photometric quantities of the two standards are compared in detail. Finally, the road light distributions and photometric quantities are calculated based on CIE and IESNA standards in the case of several urban roads with different lanes and luminaries arrangement. These results indicate that the difference about illuminance between CIE and IESNA is very slight. However, the luminance, especially the longitudinal road surface luminance uniformity has obvious difference between the two standards.

8834-28, Session PMon

High efficiency decoupling lightguide with optical structure design

Jian-Fong Jhou, Jong-Woei A. Whang, Tzung-Han Lin, Kai-Cyuan Chan, National Taiwan Univ. of Science and Technology

(Taiwan)

According to the U.S. Green Building Council (USGBC), the quality green building has low energy consumption and comfortable lighting. In general, Natural Lighting Illumination System (NLIS) is a feasible solution to reach the quality green house. However, the optical design in NLIS may have some limitations and problems in light emission. In this paper, we propose a novel design to uniformly decouple the light. And it is able to solve light pipe problems. The design component has two major features. The first feature is to decouple the light from the light pipe and transmits the light simultaneously. The other is to keep the distribution of the light consistent after decoupling. According to the étendue conservation theorem, a perfect optical system produces an image with the same étendue as the source. Due to this reason, we design an optical decoupling structure whose shape is a trimmed cone with several cylinder branches. In the optical pipe, the decoupling light guide decouples the source light and delivers it to each branch efficiently. The branch structure is designed to be inserted into the side of the cone with a specific tilt angle. By adjusting the tilt angle and diameter for individual branch, the uniformity of light transmission is controllable. In order to have high transmission efficiency, we make the incident angle and the exit angle of the light beams consistent as possible. In our experiment, these parameters can be optimized for specific applications.

8834-29, Session PMon

Design and analysis of a mathematic module about compensation of color difference and color temperature in innovative solar concentrator

Ping-Kuang Chen, Hung-Shing Chen, Kai-Cyuan Chan, Jong-Woei A. Whang, National Taiwan Univ. of Science and Technology (Taiwan)

In recent years there are many studies and applications of solar energy. The purpose of it is to guide sunlight into buildings for illumination to achieve the goals of energy conservation and carbon reduction. The concentrators in Natural Light Illumination System (NLIS®) have excellent light collecting effects; however, in application of lighting, light ray after passing through NLIS® will produce color difference and variation of color temperature problem which will affect the quality of illumination.

In order to solve the problems of color difference and variation of color temperature, we simulate different correlated color temperature (CCT) of sunlight by multi-spectrum light source and focus on the analysis of color difference and variation of color temperature of NLIS®, constructing a mathematic formula of color temperature conversion with the goal of designing a mathematic model for light source compensation and correction.

This mathematic model can be used to calculate the compensation of artificial light source in NLIS® .Therefore we can achieve the best configuration accordingly to reach best effect and quality of illumination.

8834-30, Session PMon

High uniformity innovative of the mixed light coupling structure

Yi-Chun Lin, Jong-Woei A. Whang, Tzung-Han Lin, Kai-Cyuan Chan, National Taiwan Univ. of Science and Technology (Taiwan)

With the advance of science and technology, the green energy plays an important role for human living. The natural light, as one kind of illumination, provides the most comfortable experience for human eye's perception. In our previous works, the natural light guiding system has successfully transfer outdoor natural light into the indoor environment for energy saving and health purposes.

Due to the varying incident angle of sun light, energy and color temperature change overtime. When people are using natural light guiding system, it is necessary to monitor and maintain the quality of indoor lighting simultaneously in real time. However, the uniformity of the mixed light is a challenging issue and needed to be solved.

In this research, we focus on developing a novel structure which integrates two light sources. Traditionally, the integrating sphere and light pipes are used for mixing light. Different from that, our structure has the mixed light coupling function.

In this design, the nature light is initially transferred into this element, and then additional artificial light is mixed together for improving the uniformity. This mixing light element consists of the light guiding mechanism and compound parabolic concentrator(CPC) structure, which aims to make the light emitting angle adjustable. It is proofed that this design induces better light uniformity than our previous works. Since we partially use the artificial light, the color temperature and the light intensity are controllable as well.

8834-31, Session PMon

A wedge-shaped structure prism of static solar concentrator in natural light illumination system

Chen-You Wang, Kai-Cyuan Chan, Tzung-Han Lin, Jong-Woei A. Whang, National Taiwan Univ. of Science and Technology (Taiwan)

Natural light is one kind of inexhaustible and environment friendly energy. It is able to replace parts of traditional illumination by additional guiding designs. In this paper, we reveal a light guiding system which is able to efficiently collect and transmit the outdoor natural light. This system includes a solar concentrator, optical pipes and light emitters. To improve the efficiency of light collection, we focus on optimizing the arrangement and structure of wedge-shaped prisms. In the solar concentrator, many wedge prisms with specific angles are ingeniously arranged for reducing the number of junctions. This design will avoid energy loss and concentrate light beam during transmission.

Besides, we reveal a mathematical model to simulate the parallelism which is composed of various kinds of materials. We expect the compression of light intensity will be improved. Finally, the light is delivered to emitter via optical pipes for indoor illumination.

This guiding system has the advantages of the traditional solar concentrator in collecting light. It also reduces the complexity of traditional designs in light transmission and emission. Our design is cost efficient, and the experimental result shows its feasibility.

8834-32, Session PMon

High efficient solar tracker based on a simple shutter structure

Jin-Jia Chen, Te-Shu Liu, National Changhua Univ. of Education (Taiwan); Kuang-Lung Huang, MingDao Univ. (Taiwan); Po-Chih Lin, Te-Yuan Wang, National Changhua Univ. of Education (Taiwan)

In many photovoltaic (PV) or sunlight-illumination systems, solar trackers are always essential to obtain high energy/flux concentration efficiency, and that would lead to increase cost and extra power consumption due to the complex structure and heavy weight of the trackers. To decrease the cost while without sacrificing efficiency, a Fresnel-lens concentrator incorporated with a simple and cheap shutter, which consists of high reflective acrylic mirrors instead of conventional trackers, is proposed in this paper to provide solar tracking during the daytime. Thus, the time-variant and slant-incident sunlight rays can be redirected to vertically incident upon the surface of the Fresnel lens by appropriately arranging acrylic mirrors and swinging them to the proper slant angles with respect to the orientation of sunlight. The computer simulation results show that a flux concentration efficiency over 90%, as compared with the efficiency

of directly normal incident sunlight, can be achieved with the mirror reflectance of 0.97 and for any solar incident angle within ±75 degrees to the normal of the Fresnel lens. To verify the feasibility and performance of the concentrator with the proposed shutter, a sunlight illumination system based on this novel structure is demonstrated. Both computer simulation and practical measurement results for the prototype of the sunlight illumination system are also given to compare with. The results prove the simple and high efficient shutter applicable to general PV or sunlight-illumination systems for solar tracking.

Optical design for uniform color mixing illumination system

Peng Liu, Huihui Wang, Rengmao Wu, Yang Yang, Zhenrong Zheng, Haifeng Li, Xu Liu, Zhejiang Univ. (China)

In many applications, the emitting light from LEDs with different colors need to be mixed together on a large-scale target plane and this illumination mode is usually generated by a diffuser. Abandoning the traditional method, we proposed a LED color mixing method which can produce large-scale illumination with high color uniformity. This method can be divided into two steps: irradiance array scheme and design of LED lens. With this method, an independent rectangular irradiance distribution is generated by each lens unit, as many as LED lens units with different colors are integrated on a LED module unit and the large scale color uniform illumination is obtained by arraying the irradiance distribution produced by each LED module unit. Thus, the key to the method is to design a LED lens which can generate required irradiance distribution. By numerically solving a set of partial differential equations restricted by a mapping relationship, an initial lens model is obtained. However, the pattern generated by the initial lens is not a strict rectangle and a dark zone will occur at the joint of the neighboring illumination units. Considering the consistency of irradiance uniformity between the central area and the marginal area of the target plane, a merit function with the irradiance of the dark zone involved is adopted, optimization is conducted with the downhill simplex algorithm to obtain an appropriate lens model. By optimization, the irradiance uniformity is improved from 0.8907 (relative standard deviation, RSD) to 0.0773 in one example. At last, a 3?3 array of LED module units is designed, and a desired result with high color uniformity is obtained. This color mixing method is feasible and practical, and is superior to the existing methods.

Stackable static solar concentrator with Hexagonal design

Chien-Cheng Su, National Taiwan Univ. of Science and Technology (Taiwan)

With the progress of modern technology, people begin to take the issues of environment protection and green energy seriously. Natural and healthy illumination becomes the same goal for mankind.

Sunlight collectors can be divided into two types: one is the active-form system which follows the sun's track based on the trajectory of sunlight and guides natural light into buildings for indoor illumination. Another is the passive-form system which has the features of low cost and eco-friendly without the needs of electrical power and control components, leading natural light directly into the indoor target areas.

This study proposes a new kind of passive concentrator. With the expansible characteristic based on the regular-hexagon design, as many as desired of the regular-hexagon concentrators can be stacked perfectly together to form a honeycomb-like static concentrator. The strength of this concentrator is that we can significantly increase the scope of the received light and expand the light receiving area freely. Moreover, we can utilize this characteristic to reduce the number of the optical fibers connected to the concentrators for transmission so to decrease the cost and bring a natural green illumination to human beings.

8834-35, Session PMon

A high efficiency plane lighting concentrator using round-shape prism structure to compress sunlight for indoor illumination

Chia-Min Lin, Jong-Woei A. Whang, Chun-Han Chou, Shih-Chi Tai, National Taiwan Univ. of Science and Technology (Taiwan)

In recent years, green energy has undergone a lot of development and has been used for many applications. Currently, energy-saving and carbon dioxide reduction are the most critical issues faced by the globe. Therefore, solar energy should be used as much as possible. Many research studies have focused on illumination with sunlight as a means of saving energy and creating healthy lighting. To create a low-cost collector that can be easily installed on a large building, we have designed a static concentrator to collect sunlight for indoor illumination. Prismatic elements are typical devices of natural light illumination system for redirecting and collecting daylight. Based on the principles of optics, this paper presents a new type mathematical matrix static solar concentrator. We collect sunlight using a plane round-shape concentrator, compressing light beams and transmitting light beams through a channel module from the export outlet of the concentrator, and we transmit the high-density light via optic fiber cable for indoor illumination. In addition, we define an optical energy density factor to calculate the value of the light gathering efficiency of the sunlight on the concentrator. This indicator shows the illumination of collected sunlight on the export side of the concentrator. Furthermore we design a prism reflection structure in the export, which could make the aperture of light channel smaller. We save 50% of optic fiber usage, but the efficiency remains. Our team has evaluated the concentrator's efficiency by the indicator. We have designed a high throughput plane lighting concentrator using round-shape stacked structure. This system will provide a great number of benefits for the people who use it.

8834-36, Session PMon

A static solar concentrator with hybrid multilayer stack structure for natural light illumination system

Chia-Min Lin, Jong-Woei A. Whang, Chun-Han Chou, Zong-Heng Sie, National Taiwan Univ. of Science and Technology (Taiwan)

Today, there is a shortage of the energy in the world. Green energy is the best alternative energy because there is low environmental impact and an unfailing supply. Besides, some renewable energy sources have geographical or environmental imit. In the recent years, Energy-saving and carbon dioxide reduction are the most critical issues currently faced by the globe. Therefore, in daytime, solar energy should be used as much as possible. In addition to the use of solar cell, daylight illumination is also an important access to solar energy. Our team designs a static concentrator with vertical stack structure. In general, static concentrators have better collection efficiency when sunlight just enters the concentrator perpendicularly. We design a compound curved surface which can increase collection efficiency for different sun's azimuth. And, we use prism and geometric structure to make sure that concentrated sunlight will achieve total reflection on each layer and transmit completely to port. The design can decrease the divergence angle and improve coupling efficiency with transmission system. Although new natural light illumination system can effectively guide collected sunlight and send it to the basement or to other indoor places. We have designed a static solar concentrator with hybrid multilayer stack structure to gather and concentrate the collected sunlight from the natural light. Our system can effectively deliver more than 60% energy transmission. We have designed, simulated, and optimized a light collection system, which our analysis shows equals the qualities of a traditional lighting system.

High efficiency half-cylindrical Fresnel lens solar concentrator assisted by Cassegrain structure

Chia-Hsing Chu, Jong-Woei A. Whang, National Taiwan Univ. of Science and Technology (Taiwan)

Due to the energy crisis and enhancing awareness of environmental protection, many scientists have focused on the research of energy saving recently, and the application of sunlight has been one the most popular issues. There are two types of solar concentrators for the purpose of collecting sunlight: one is active and the other is dynamic. The dynamic concentrator moves following the track of sun to direct sunlight into buildings for indoor illumination; a static concentrator has the advantage of electricity-free, guiding sunlight directly into the target areas. The latter type not only is low-cost but also environmental friendly.

In this paper, we develop an innovative static solar concentrator, setting Fresnel lens according to the sun-track on a half-cylindrical surface for collecting sunlight of all angles to the same focal point, and we call it half-cylindrical Fresnel lens concentrator. Next we set a convex lens under the focal point to generate parallel light from the collected light to the output and set up a Cassegrain reflector structure around the half-cylindrical Fresnel lens concentrator to generate light beam by gathering the collected light to the output again to form a new cascadable solar concentrator combining two optical structures which not only considerably increase the light collecting efficiency but bring great advantages to natural light guiding systems and green illumination. To sum up , this new developed static solar concentrator is named high efficiency half-cylindrical Fresnel lens solar concentrator assisted by Cassegrain structure.

8834-38, Session PMon

New complex circular light concentrator applied to lamps design for the convergent light type with OLED light source

Wei-Shao Su, National Taiwan Univ. of Science and Technology (Taiwan)

Traditional light sources have been gradually replaced recently, people start to develop a new alternative light source, Organic Light Emitting-diode(OLED) which compared to other light source has advantages like light, thin and flexible, and OLED itself can be a display and light-emitting on both side of OLED, we can use these characteristics of OLED in application of illumination to design creative new lamps.

In my research, we design a much more collimation and centralized illumination instrument under satisfaction convergence light type of government rule and also thin sized. We do light source secondary optical design according to uniform surface Lambertian light-emitting type of OLED, we design a new complex circular light concentrator on the top of the OLED, this circular light concentrator is composed of a lateral array of prisms structure to collect light in each region and then guide to the center of circular disk. It can not only converge the large area light source and enhance the brightness of the center to 55.1%, but also reduce the amount of thickness. With the new light concentrator, OLED will have a higher level of application for illumination.

8834-39, Session PMon

Set of new wide-angle sun light collection component with high-efficiency

Tzu-Tun Liao, Jhong-Wei Huang, Kai-Cyuan Jhan, National Taiwan Univ. of Science and Technology (Taiwan)

Nowadays many Countries have focused on green buildings development. The U.S. Green Building Council (USGBC) defines that “a good green building must have lower energy consumption and comfort illumination”, so the natural light illumination system is considered a better illumination system than the artificial ones regarding color and health issues.

The core of natural light illumination system is the design of optical components for sunlight gathering. However, the focus of the optical component design is often limited to the incident angle of sun light and the direction of receiving light, which in result leads to the decrease of gathering efficiency because of the movement of sun. The goal of this study is to focus on the setting of light-receiving components which can break the limitation of the incident angle of sunlight by using a special pyramidal angle of curvature to design the optical component. It also greatly enhances the light gathering efficiency. The optical components can be joined together as a sunlight collecting sheet, four sheets as a collection group. The number of the group’s light output is decreased to one, which in result efficiently reduces the cost of the optical fibers needed for light transmission.

The new structure of the design is expected to replace the existing passive collection optical components on market place in the future. It can be posted on the roof to gather sunlight for indoor illumination and reduce energy consumption for the goal of green building.

8834-40, Session PMon

A complex design concluding collecting and transmitting subsystems for natural light illumination system

Chen-Yen Huang, Jong-Woei A. Whang, Ching-Wen Hsue, National Taiwan Univ. of Science and Technology (Taiwan)

The greenhouse effect is an increasingly serious environmental issue which has drawn much attention in the area of the environment protection. Therefore the development of green energy industry is imperative. Natural light illumination system is a novel and eco-friendly illumination system directing sunlight into buildings for illumination without the opto-to-electricity conversion, which can efficiently reduce the loss of the solar energy in the transition between different energy types. This system can be divided into three subsystems: 1) collecting subsystem; 2) transmitting subsystem; and 3) emitting subsystem.

A coupler is needed to reduce the loss of energy during the coupling of the three subsystems. The study designs a combination of collecting subsystem and transmitting subsystem. The light collecting components consists of two parabolic mirrors, using its optical properties, confocal both mirrors to transmit light into transmitting subsystem. The collecting subsystem collects light via a multi-reflection angle of reflection surface amending light track to the lens and focused through the lens of the optical properties, hitting the lens connected to the next collecting subsystem to achieve the demand of light transmission. In this design, the two subsystems are integrated and can reduce the loss in the transmitting process between the two subsystems without via the other coupling. This design enhances the efficiency of the natural light illumination system for the utilization of solar energy.

8835-1, Session 1

Accelerated optical polymer aging studies for LED luminaire applications

Edgar G. Estupinan, Peter Wendling, Marijan Kostrun, OSRAM SYLVANIA Inc. (United States)

There is a need in the lighting industry to design and implement accelerated aging methods that accurately simulate the aging process of LED luminaire components. In response to this need a robust, flexible and reliable system has being built to study the aging characteristics of optical polymer materials and it has been employed to study a commercially available LED luminare diffuser. The experimental system consists of a "Blue LED Emitter" and a working surface (hot plate). The "Blue LED Emitter" is composed of a mechanical assembly that holds the LEDs at a desired distance from the hot plate, the optical assembly that controllably spreads the blue light to regions of the working surface, and the thermal assembly which maintains near-room temperature of the active LEDs. The distance between the optical assembly and the hot plate is precisely controlled by micrometer heads and the LEDs are carefully calibrated as a function of power and distance from the optical assembly. Several improvements were made to the original design in order to increase the temperature homogeneity of the heating plate as well as quantifying and minimizing the local heating of the samples due to the blue light itself which was shown to substantially distort the intended temperature of the samples under investigation at high intensities. Results of the commercially available LED luminare diffuser studies are presented which include a discussion of transmission studies, accelerated factors related to the life of the luminare and aging effects.

8835-2, Session 1

Effect of heat and short-wavelength visible radiation on phosphor-embedded LED encapsulant

Prathika Appaiah, Nadarajah Narendran, Yiting Zhu, Yi-Wei Liu, Indika U. Perera, Rensselaer Polytechnic Institute (United States)

The application of the light-emitting diode (LED) in general lighting has grown steadily over the past several years. The most common approach to producing white light is by using a short-wavelength semiconductor such as gallium nitride with a layer of yttrium garnet (YAG:Ce) phosphor, which produces a broad spectrum light covering the visible range. In this phosphor-converted (PC) method, the phosphor is dispersed within the encapsulant surrounding the LED die. The degradation of the encapsulant and phosphor plays a vital role in determining the useful lifetime of the LED. In white LEDs the encapsulant material is usually epoxy or silicone. The phosphor-embedded encapsulant is subjected to short-wavelength radiation and heat from the LED chip. The objective of this study was to evaluate the effects of short-wavelength radiation and heat on the photo-thermal degradation of the LED encapsulant, which leads to LED light output degradation. In this study, light output degradation as a function of heat and irradiance for different phosphor concentrations in the encapsulant were analyzed. Color shift of the different samples subjected to photo-thermal degradation also was studied. This study will help give an understanding of the individual contributions of heat and short-wavelength radiation to reduced reliability of the LED package. The details of the experiment and the results will be presented.

8835-3, Session 1

Thermal management of the remote phosphor layer of an LED system

Indika U. Perera, Nadarajah Narendran, Rensselaer Polytechnic Institute (United States)

Generally in a white light-emitting diode (LED), a phosphor slurry is placed around the semiconductor chip or the phosphor is conformally coated around the chip to covert the narrowband, short-wavelength radiation to a broadband white light. Over the past few years, the remote-phosphor method has provided significant improvement in overall system efficiency by increasing the conversion rate. It has also shown to improve LED useful life by slowing lumen depreciation, since the phosphor layer is spaced apart from the hot LED die. However, increased light output and smaller light engine requirements are causing high radiant energy to be incident on smaller-footprint, remote-phosphor plates, thus heating the phosphor layer, especially when the phosphor material has low conversion efficiency. Phosphor layer heating can negatively affect performance in terms of luminous efficacy and life. In such cases, the performance of remote-phosphor LED lighting systems can be improved by suitable thermal management that can reduce the temperature of the phosphor-embedded encapsulant. As a solution to this problem, a perforated metal plate was embedded within the phosphor layer to remove the heat, and the parameters that influence the effectiveness of heat extraction were studied. These parameters include the metal-to-phosphor layer interface area and the surface finish of the metal plate. The temperature of the remote-phosphor encapsulant surface was measured using IR thermography. A reduction of temperature in remote-phosphor encapsulant surfaces was observed as the conduction area increased. The details of the experiment and the results will be presented.

8835-4, Session 1

Thermal behavior of phosphor in phosphor-converted white LED

Jin Hwan Kim, Jong H. Choi, Moo W. Shin, Yonsei Univ. (Korea, Republic of)

We investigated the optical and thermal characteristics of remote type light emitting diode packages as a function of location of phosphor layer. In order to fabricate the remote type package, a silicone-epoxy resin and mixture of resin and phosphor (YAG) were dispensed alternately on a bare package. The location of phosphor layer was able to be varied by controlling the dispensing time of a dispenser. The thickness and distance from the LED chip of the phosphor layer have been observed from SEM images. The junction and phosphor temperatures were determined by a thermal transient method and a direct thermocouple measurement, respectively. The phosphor temperature was always higher than the junction temperature, e.g. the junction and phosphor temperatures were measured to be 72.5 °C and 90°C, respectively when the phosphor layer-chip distance is 150?m. The difference was found to increase with the distance. Thermal simulation based on the finite volume model verified the experimental results and demonstrated that the thermal resistance between the phosphor layer and the LED chip is a major determinant of the temperature. Optical spectrum was measured using an integrating sphere, and showed that the optical power loss at the phosphor layer is in a range of 5 to 30 %. The conversion efficiency of phosphor was found to decline with temperature. While the remote type package was reported to extract more scattered photon, the optical output was found to decrease due to the poor thermal characteristics.

8835-5, Session 1

Accurate measurement of LED lens surface temperature

Indika U. Perera, Nadarajah Narendran, Yi-Wei Liu, Rensselaer Polytechnic Institute (United States)

Performance and reliability of high-power light-emitting diodes (LEDs) improve with better thermal management. In conventional white LEDs,

the chip is surrounded by an encapsulant with embedded phosphor particles. The increased heat in high-flux LEDs degrades the lens material and the phosphor, reducing overall performance and reliability. Past studies have shown large errors in temperature measurement when the temperature of an LED primary lens is measured with a thermocouple. This is mostly due to absorption of radiant energy by the thermocouple. The erroneous temperature measurement can cause problems during the design and measurement stages of LED luminaire development.
To understand the problem in using thermocouples to measure LED lens surface temperature and to find a solution, an experimental study was conducted. Infrared (IR) thermography was used as the reference temperature measurement in this study because its measurement values are unaffected by high radiant flux in the visible range. After studying the thermocouple wire metallurgy and its radiation absorption properties, a suitable material was identified to shield the thermocouple from visible radiation. A silicone elastomer with optical and thermal properties similar to the primary lens surface was used to maintain the thermal interface between the lens surface and the thermocouple sensing junction.
The deviation between thermocouple lens temperature measurement values and IR measurement values were within ±3 °C after adopting the radiation shielding method. The shielding layer was placed along the thermocouple lead wire and the thermocouple sensing junction was kept exposed. Experiment details and results will be presented in this paper.

8835-6, Session 2

Context-aware tunable office lighting application and user response

Nancy H. Chen, OSRAM SYLVANIA Inc. (United States); Jason Nawyn, MIT Media Lab. (United States); Maria R. Thompson, Julie Gibbs, OSRAM SYLVANIA Inc. (United States); Kent Larson, MIT Media Lab. (United States)

Multiple color channel LED lighting fixtures allow tuning of both intensity and color. Consequently, highly tailored lighting can be applied according to user needs and preferences. Besides improving performance, energy use can also be reduced since the brightest illumination is applied only when necessary. In an example application, low-activity or vacant areas of a 5-zone office are lit by low energy illumination, which can reduce energy consumption to 25-65% compared to typical full-time, full-brightness, office-wide illumination. The availability of color also allows communication functions (vacancy status, do not disturb) and additional aesthetic design possibilities. To reduce user burden in frequent switching between various illumination settings, an activity recognition sensor network is used to identify various office activities. The illumination is then adjusted automatically to satisfy the instantaneous needs of the occupants. A handheld mobile device provides an interactive interface for specifying user illumination preferences and gathering feedback regarding user impressions. Activity-triggered queries collect contemporaneous feedback that reduces reliance on memory; immediate previews of illumination preference options are also provided. Through mobile queries and post-experience interviews, user feedback was gathered regarding automation, colored lighting, illumination preferences, query method, and activity recognition accuracy. As might be expected, user impressions to automation and colored lighting were quite varied, as indicated by response words such as fun, pleasant, appropriate, satisfactory, distraction, isolated, and unfamiliar. Not surprisingly, individual color preferences affected user satisfaction. Positive reaction from a meaningful, though not universal, fraction of users indicates reasonable application potential, particularly as personal preferences and control are accommodated.

8835-7, Session 2

Color preferences revealed by statistical color rendition metrics

Anqing Liu, Rensselaer Polytechnic Institute (United States); Arunas Tuzikas, Arturas ?ukauskas, Rimantas Vaicekauskas, Pranci?kus Vitta, Vilnius Univ. (Lithuania); Michael S. Shur, Rensselaer Polytechnic Institute (United States)

The statistical metric of color rendering uniquely quantify the characteristics of color quality of illumination. Our color rendition engine [1] based on the statistical metric of color rendering allows for the subjective assessment of color rendition preferences by continuously changing the tetrachromatic color blend from dull to saturated at different correlated color temperatures. We now report on using the color rendition engine for revealing individual and cultural differences in color quality preferences. The research using 300 American and Chinese graduate students demonstrated that the majority of individuals preferred the color blend with the same statistical figures of merit on the average but with a much larger spread of blends for Americans. For both groups, the color rendition preferences depended on the object being illuminated. This was demonstrated by illuminating a set of common colored objects and three different paintings. We conclude that the color quality of lighting can be optimized using the feedback to change the spectral power distribution of the illuminating source depending on the needs of an individual observer and on an object being illuminated as was proposed in [2].

8835-8, Session 2

Intensity ratios of multicolor LEDs for optimal lighting performance

Ivan Moreno, Daniel Huerta, Univ. Autónoma de Zacatecas (Mexico)

Multicolor LEDs offer real-time color tunable control of light emission as never before in history. Given a set of available colored LEDs with known specifications, many possible combinations of relative light fluxes produce the same correlated color temperature (CCT). But only one combination maximizes luminous efficacy and color rendering index. In this work, simple formulas are given for the optimal intensity ratios of colored LEDs as a function of peak wavelengths, bandwidths, and CCT. In other words, a simple empirical and phenomenological model gives the relative light fluxes of LEDs in order to achieve the highest luminous efficacy and color rendering index for different CCTs. The model is constructed from numerical results reported in literature and some other calculations.

8835-9, Session 2

Phosphor crystals for tailored spectrum LEDs

Partha S. Dutta, Aloka Khanna, Ben McCarty, Rensselaer Polytechnic Institute (United States)

The pc-LED architecture is most suitable for creating a wide gamut of tailored full spectrum miniaturized artificial light sources. However, there are many challenges in developing tailored full spectrum light sources that could meet both the human factors and the energy saving gains simultaneously. The research on phosphor crystals are motivated for designing future lighting systems by using fundamentally different color conversion architectures than what is used in current commercial LEDs. The usage of optically clear (non-scattering) phosphor substrates or thin films will enable efficient ways for spectrum generation, reduced loss of optical power (that occurs by multiple scattering events within the powder phosphor regions in current pc-LEDs), reduced thermal quenching properties as well as reduced environmental degradation of the well known high efficiency phosphors. The development of crystal growth processes for phosphor alloys from high temperature melt and flux will be presented. Classes of phosphor compounds being researched include: broad band phosphors such as thiogallates (SrCaMgBa)Ga2(SSe)4:Eu2+, Ce3+, alloyed sulfides and selenides (SrCaGa)(SSe):Eu2+ Ce3+ , silicates (Ba1-x-ySrxCay)SiO4:Eu2+ , garnets

(YAG: Ce3+ micro-crystals, oxynitrides Lix(MgSrCaBa)ySiAlON: Eu2+, Ce3+ types and narrow emission phosphors such as tungstate and molybdate types [(SrCaMgBaYGdLa)x(WMo)yOz:Eu3+, Ho3+, Dy3+, Pr3+, Sm3+, Tb3+. Our studies have shown that melt and flux grown phosphor crystals exhibit many interesting features compared to solid state synthesized powders such as (a) higher excitation efficiency, (b) extension of charge transfer bands from UV to the blue regions, (c) reduced degradation with moisture exposure, etc.

8835-10, Session 2

LED champing: statistically blessed?

Zhuo Wang, OSRAM SYLVANIA Inc. (United States)

LED champing (smart mixing of single LEDs to match the desired color and lumen output) and color mixing strategies have been widely used to maintain the color consistency of light engines. The light engines with champed LEDs can easily achieve a color consistency of a couple MacAdam steps with widely distributed LEDs to begin with, i.e. the chromaticity of the light engines is visually matched. For many critical applications such as the merchandise lighting, the champed LEDs are proven to perform similarly compared to the fine binned LEDs.

From a statistical point of view, the distributions for the final color coordinates and the flux are studied. Several different distributions, including the Gaussian distribution and uniform distribution are assumed in the study. The results show it is not always true that the final color coordinates will have a tighter distribution after champing. Based on the analyses, the final distribution for the color coordinates as well as the flux values can be approximated with Gaussian for a large number of LEDs. The means and the standard deviations for the color coordinates and the flux are derived, which can work with the strategies for process improvement such as Six Sigma and are instrumental to the mass production quality control.

8835-28, Session PMon

Optical design for adjustable LED projection light with high utilization factor and uniformity

Yi-Chien Lo, Jhih-You Cai, Ming-Siou Tsai, Che-Chu Lin, Chong-Jhih Jiang, Ching-Cherng Sun, National Central Univ. (Taiwan)

In this paper, we present a new design, for LED projection light which can adjust its pattern size. The optical system is composed of a reflector and a lens. The pattern with high uniformity can be found in not only wide illumination but also narrow mode. Then, it also have high optical utilization factor. Furthermore, its performance is demonstrated by several measurements.

8835-29, Session PMon

Optical design of bicycle headlamp with low and high beam based on white LEDs

Jhih-You Cai, Yi-Chien Lo, Ming-Siou Tsai, Che-Chu Lin, Chong-Jhih Jiang, Ching-Cherng Sun, National Central Univ. (Taiwan)

In this research, we designed a bicycle headlamp, which provided the low beam and the high beam in different modes. Most of the users care about these condictions. In the two modes, one was good lighting on the roadway and met the K-mark regulation; the other one was high-density energy of light pattern. Before the optical design, we build a precise optical model for a high power LED produced by CREE in mid-field verification to make sure the accuracy of our simulation. After optical model of the LEDs, We used multiple-reflective surfaces to perform the low beam based on a high-power chip white LED. Some of the reflective surfaces made a high-contrast cut-off line light pattern on a plan at a distance of 10 m, while others created a uniform light pattern and illuminated the region of the K-mark regulation on the roadway. In the high beam mode, we used the other LED as a light source. We also used a reflector and lens to collect and project the light, which enhanced the central illumination on a plan at a distance of 10 m. Finally, we finished our secondary optics of bicycle headlamp with low and high beam.

8835-30, Session PMon

Effects of pitch and angle of the asymmetric optical diffraction component for LED fog lamp

Hsi-Chao Chen, Chi-Hao Yang, Chen-I Lin, Houe-Sin Tsai, National Yunlin Univ. of Science and Technology (Taiwan)

Light-Emitting Diodes (LEDs) have the advantages of small size, long lifetime, fast response time (?s), low voltage, good mechanical properties and environmental protection. Furthermore, LEDs could replace the halogen lamps to avoid the mercury pollution and economize the use of energy. Therefore, the LEDs could instead of the traditional lamp in the future and became an important light source. The proposal of this study was to investigate the effects of pitch and angle of the asymmetric optical diffraction component for a LED fog lamp. The novelty LED fog lamp was assembled of a reflector and an optical transparent differential component. The optimized design of the pitch and angle of the asymmetric transparent differential component was simulated by TracePro software. The design results must meet the standard of European regulations of ECE R19 Class F3. The pitch of asymmetric diffraction component was studied from 1mm to 6mm. The angle of the triangle structure of every pitch was modulated by the stray light from 5 to 32 degrees far from the center of diffraction component. The angle variant resulted from the light projection of the triangular structure of different pitch's position. The simulation results exhibited the optimal pitch is 5 mm by the best total luminous flux and the luminous efficiency. The optical efficiency could reach to 90% by the 92% reflection rate of the reflector. Also, the stray light could to meet the ECE R19 Class F3 regulation. Final, the experimental result of the pitch of 5mm diffraction component mockup could match the simulation result.

8835-31, Session PMon

Investigation of color temperature of high power white LEDs array modulated by mixing of monochrome or bicolor LEDs

Hsi-Chao Chen, Wei-Jhe Chen, Chi-Hao Yang, Jia-Hao Jhou, Yuan-Jui Chang, National Yunlin Univ. of Science and Technology (Taiwan)

The advantages of light-emitting diodes (LEDs) have the small size, long life time, low power consumption, no UV-IR light, wide range of color temperature, fast-switching response and mercury-free etc. Furthermore, LEDs could tune light intensity by digital modulation for the life. Therefore, LEDs would replace traditional light source in the future. The proposal of the study was investigated the variation of color temperature in a high power light-emitting diodes (HP-LEDs) array modulated by monochrome or bicolor LEDs for intelligent lighting. The HP-LED was used a 3 Watt LED and the LED array was 3?3 square modulation was tuned by 3W red or yellow LEDs. There are three LEDs array: 5W(white)+4R(red), 5W+4Y(yellow), and 5W+2R+2Y were assembled in the research for the investigation of color temperature. The experimental results exhibited that 5W+4R LEDs array had the broader range of color temperature from 8000 K to 3000 K than the short range of 5W+4Y LEDs array from 8000 K to 5000K. In additional, the color temperature of 5W+2R+2Y LEDs array could adjust broadened color temperature range from 8000 K to 3000 K and improve the steep status of color temperature of 5W+4R LEDs array. However, the 5W+2R+2Y LEDs array is a good choice for the color temperature adjustment in the LED street light.

8835-32, Session PMon

Adjustable and automated system to obtain 3D photometric patterns

Margarita Tecpoyotl-Torres, Jose G. Vera-Dimas, Saul E. Martinez-Fabian, José L. Mendoza-Zuñiga, J. Jesús Escobedo-Alatorre, Univ. Autónoma del Estado de Morelos (Mexico); Oscar G. Ibarra-Manzano, Univ. de Guanajuato (Mexico)

A complete adjustable and automated system has been developed on the base of four blocks: the first one is the mechanical and adjustable structure, which is composed by a mobile base and a rectangular arc, where the photo-detector is located. The structure describes semi-spherical trajectories by means of two stepper motors.

The second stage corresponds to the automation of the structure movements. For controlling the motors and data acquisition, a microcontroller is employed that in turns helps keeping the cost of the overall system low. One of the stepper motors is located on the lateral axis of the device; that displaces the sensor along a semi-circular trajectory of 170°, almost half meridians; the other one is located at the base of the illumination source, which enables it to realize an almost complete rotation around its axis. The precision is increased with two rotation sensor located on the opposite side of the arc and on the mobile base. Additionally, before the data obtained from the photo-detector arrive to the microcontroller, a stage of signal conditioning is realized.

The third block corresponds to the voltage source, with the capacity to satisfy all energy requirements of the system. This stage is necessary in order to obtain a simple handling system, and to avoid the use of different voltage sources.

Finally, the last stage is formed by the graphical interface. The communication protocol between the data acquisition stage and the computer is USART. The graphical user interface (GUI) is developed using C#.

Evaluation of optical and chromatic properties under electrical and thermal coupling in solid state lighting systems

Han-Kuei Fu, Yi-Ping Peng, Chien-Ping Wang, Hsin-Chien Chiang, Tzung-Te Chen, Chiu-Ling Chen, Pei-Ting Chou, Industrial Technology Research Institute (Taiwan)

For energy-saving, high efficiency and low pollution, the lighting of LED systems is important for the future of green energy technology industry. The solid state lighting becomes the replacement of traditional lighting, such as, light bulbs and compact fluorescent lamps. Because of the semiconductor characteristics, the luminous efficiency of LEDs is sensitive to the operating temperature. Besides increasing the luminous efficiency, effective controlling electricity and thermal characteristics in the design of LED lighting products is the key point to achieve the best results. LED modules can be combined with multi-grain process or through a combination of multiple LED chips. Accurate analysis of this LED module for the electrical, thermal characteristics and high reliability is the critical knowledge of modular design. In this report, we studied the electrical and thermal coupling phenomenon in solid state lighting systems to analyze their reliability. By experiments and simulations, we obtained the apparent variation of temperature distribution of LED system due to differences of their forward voltages and thermal resistances. These events may reduce their reliability. Besides, the evaluation of optical and chromatic properties was based on the variation of temperature distribution and current of LED system. This is the key technology to predict the optical and chromatic properties of LED system in use.

8835-34, Session PMon

The low-frequency noise spectrum analysis of the reliability of the InGaN LED

Tzung-Te Chen, Chun-Fan Dai, Chun-Wen Chu, Han-Kuei Fu, Chien-Ping Wang, Pei-Ting Chou, Industrial Technology Research Institute (Taiwan)

In recent years, with extensive use of InGaN LED, how to assess the LED quality and further improve LED reliability is very important. In this report, the noise spectrum measurement techniques were used to assess the amount of defects in the InGaN LED devices and compare with its ESD tolerance test result. The source of low-frequency noise are attributed to the carrier number or mobility fluctuation. It is because the carriers are randomly trapping-detrapping in defect states near the interface of the semiconductor. Thus, the testing LED sample with lower defect density can exhibit lower noise power spectrum density and higher ESD tolerance. Experimental results show that the low-frequency noise spectrum measurement is more effectively distinguish the LED device reliability than the current voltage curve measurement. EMMI?SEM and TEM images show that the noise source and the cause of ESD failure of the LED device are attributed by the poor quality of the SiO2 and ITO interface.

8835-35, Session PMon

Long-term lumen depreciation behavior and failure modes of multi-die array LEDs

Asiri Jayawardena, Daniel Marcus, Nadarajah Narendran, Rensselaer Polytechnic Institute (United States)

Multi-die array light-emitting diodes (LEDs) are becoming more common in the marketplace for use in illumination applications. One of the main advantages of such packages is that the overall footprint of the LED package is small for the amount of flux produced. However, a challenge for using such a product in lighting fixture applications is the heat density and the thermal management strategy needed to keep the LED junction temperature low for reliable performance. Array configurations, such as series parallel arrangement for stringing the LED dies, also can greatly affect the long-term performance. Therefore, another challenge is the reliability of the array that allows all dies in the package to behave similarly over a long period of time. To study lumen depreciation and conduct failure mode analysis, several multi-die array samples from different manufacturers were subjected to a life test. The products were tested at the maximum case (or pin) temperature reported by the respective manufacturers. Each LED package was attached to a temperature-controlled heat sink to maintain a constant operating temperature over the test period. All LED packages were powered at 700mA DC current. The LED case temperature, voltage, and current were continuously recorded at 4 hour intervals. Each sample was tested in an integrating sphere periodically to obtain luminous flux and chromaticity values. The photometric quantities of the LEDs were measured under pulsed current condition so that the junction temperature was close to room temperature. The details of the experiment and the results will be presented.

8835-11, Session 3

LED-based automotive forward lighting: status and challenges *(Invited Paper)*

Takayuki Yagi, Masaru Sasaki, Koito Manufacturing Co., Ltd. (Japan)

Six years after the introduction of LED headlamps launched in 2007, its penetration has now been rapidly expanded. The first production LED headlamp had power consumption of 50W and weighs 1600 grams for a low beam unit. By 2011, the progress was made to have power and

weight reduction to 25W and 400 grams respectively. The innovation continues.. This presentation shows what has been accomplished and where it is going with LED-based automotive headlamps. In particular, it describes the technical challenges and achievements for LED light sources, thermal management, optical design, electronics design, and system level optimization.

8835-12, Session 3

Data format standard for sharing light source measurements

G. Groot Gregory, Synopsys, Inc. (United States); Ian E. Ashdown, byHeart Consultants Ltd. (Canada); Wilhelm Brandenburg, Brandenburg GmbH (Germany); Dominique Chabaud, OPTIS (France); Oliver Dross, Philips Research (Netherlands); Sanjay Gangadhara, Radiant Zemax, LLC (United States); Kevin J. Garcia, Breault Research Organization, Inc. (United States); Michael A. Gauvin, Lambda Research (United States); Dirk Hansen, opsira GmbH (Germany); Kei Haraguchi, Nichia America Corp. (United States); Günther Hasna, OPTIS (France); Jianzhong Jiao, OSRAM Opto Semiconductors Inc. (United States); Ryan Kelley, LTI Optics, LLC (United States); Julius A. Muschaweck, OSRAM AG (Germany); R. John Koshel, Photon Engineering LLC (United States)

Illumination design requires accurate characterization of light sources for computer aided design (CAD) software. Various methods have been used to model sources, from accurate physical models to measurement of light output. It has become common practice for designers to include measured source data for design simulations. Typically, a measured source will contain rays which sample the output distribution of the source. The ray data must then be exported to various formats suitable for import into illumination analysis or design software. Source manufacturers are also making measurements of their products and supplying CAD models along with ray data sets for designers. The increasing availability of data has been beneficial to the design community but has caused a large expansion in storage needs for the source manufacturers since each software program uses a unique format to describe the source distribution.

In 2012, the Illumination Engineering Society (IES) formed a working group to understand the data requirements for ray data and recommend a standard file format. The working group included representatives from software companies supplying the analysis and design tools, source measurement companies providing metrology, source manufacturers creating the data and users from the design community. Within one year the working group proposed TM-25 file format which was sent to IES for consideration.

This paper will discuss the process used to define the proposed format, highlight some of the significant decisions leading to the format and list the data to be included in the first version of the standard.

8835-13, Session 3

LED light recycling using double prisms

George X. Ouyang, Wavien, Inc. (United States)

A novel LED recycling scheme using double prisms is presented. Two identical triangular prisms, one cross-stacked on top of the other, are tight-fit into a mirrored light tunnel. The whole prism/light tunnel assembly is then mounted on top of an LED source, whose emitting area is the same as that of the base plane of the said prism/light tunnel assembly. Each prism acts as a tapered-down light guide in one dimension, which selectively retro-reflects high-angle light along that direction. The outer light tunnel serves as a mirrored wall that folds back any light that escapes outside the two prisms. For a given collection cone angle, the height of the two prisms is optimized using ASAP, a commercial ray-tracing software. Preliminary simulation and experimental results show promise in significantly increasing the brightness of the LED sources within the collection cone. Specifically for a 4x recycling ratio a 70% recycling gain in center illuminance has been achieved (i.e., illuminance measured in the forward direction). This scheme has advantages over previous recycling configurations due to its compactness and ease of mounting. For example, compared to Wavien's spherical reflector approach that has been previously published, the current recycling configuration is much smaller in size because instead of fitting a much larger mirrored reflector on top of the LED source, this time we're using a structure that has the same lateral dimensions as those of the LED source itself. Further improvement is also possible if optimization of various system parameters is carried out.

8835-14, Session 3

System design of a LED based gobo projector

Henning Rehn, OSRAM AG (Germany)

In the contribution we discuss the relationship between etendue and luminous flux of gobo projectors and its implications on illumination design and system architecture.

On the basis of a given projector specification, a suitable LED type can be chosen and the number of needed LEDs and the necessary system etendue can be calculated. In a next step, we show how to design a suitable illumination system with primary and secondary optics and possibly including a homogenizer. Furthermore, implications for the design of the projection lens are discussed.

8835-15, Session 4

Design of LED edge-lit light bar for automotive taillight applications

Jyh-Cheng Yu, Jia-Hao Chen, Shih-Chiang Liu, National Kaohsiung First Univ. of Science and Technology (Taiwan)

This study investigates the optical design of LED edge-lit curved light guide bar and applies to the design of automotive taillight. LEDs have been widely used in automotive lighting. However, the designs are mostly of direct backlight using arrays of LEDs with diffusive patterns above, which often causes problems such as low uniformity, glaring, and too many LEDs required. Edge-lit light guide devices have been widely used in the back light models of LCD. However, the geometry of the lighting devices in the automotive lighting is often curved, and the literatures regarding the design of curved light guide components are very limited. This study addresses the design of edge-lit curved light guide bars and the optimization scheme for uniform light emitting. An automotive taillight with LED edge-lit light bar is used as an illustrated example. The light tracing software, TracePro is used to simulate the optical characteristics of the proposed design. 90° V-cuts are used as the optical features to distribute the light, and the lead angles of the v-cut are varied to achieve the optimum axial luminous intensity. A Fuzzy optimization scheme is proposed to manipulate the anchor spacing points which continuously varies the v-cut spacing along the light bar to satisfy the requirements of Society of Automotive Engineers (SAE) regulations and the illumination uniformity requirements. This study also proposes a solution to reduce the illuminance difference between the inside and the outside of the curved section of a light bar by varying the inside and the outside thickness of light bar.

8835-16, Session 4

Effect of a light guide plate with lenticular-arrayed surface on optical output for backlight and illumination application

Tun-Chien Teng, Li-Wei Tseng, National Taiwan Normal Univ. (Taiwan)

In this paper, we investigated the optical output characteristic of the light guide plate (LGP) with microstructures engraved by a CO2 laser, which is for edge-lit backlight of liquid crystal display or illumination. Especially, the laser-engraving method is suitable for the slim large-area LGP used in LED TV backlight, and the engraved microstructure has polish surface to contribute to better optical efficiency. For higher optical efficiency, we adopted a LGP with lenticular-arrayed surface as an experimental sample. In this case, we used the laser to engrave different kinds of microstructures directly on the flat surface (opposite to the lenticular-arrayed surface) of the bare LGP, respectively. The sample LGPs were measured for spatial and angular luminance by the BM7 and Conoscope. We further compared the results with the flat LGP without lenticular-arrayed surface in order to obtain the optimal design by evaluating the effect of lenticular-arrayed surface on optical output for different kinds of microstructures. The experimental data show the peak intensity in the normal increases by 5~20% for different conditions as compared to the flat surface LGP. In addition, the simulation results were also compared to the experimental data.

8835-17, Session 4

Diffraction gratings for lighting applications

Hugo J. Cornelissen, Philips Research Nederland B.V. (Netherlands)

Sub-micron diffraction gratings have been used for two illumination application. One is to create a transparent see-through luminaire which can be used to illuminate and read a paper document. A second is a light sensor that can be used in a feedback loop to control a multicolor LED lamp. Optical design and prototypes are presented.

Diffraction gratings are demonstrated as light extraction features for light guide-based luminaires. A potential advantage is that these features are invisibly small and the light guide luminaire can have protective scratch-resistant claddings. Transparent luminaires for paper reading are designed using diffraction gratings with a pitch between 250nm – 700nm. Details of the gratings are designed with GSolver, a program that implements the RCWA-analysis approach. Results are then imported into a ray tracing program (LightTools) to complete the full system design.

Prototypes of a luminaire with a grating pitch of 275nm are fabricated by replication of a master grating onto glass light guide using Surface Conformable Nano-Imprint Lithography. Light from RGB-LEDs is injected into the light guide and extracted by the grating. The measured angular distribution compares well with the designed one.

A second application is a color sensor for an RGB-LED color luminaire. It is a transparent cover plate where locally a diffraction grating is manufactured using laser lithography. It acts as a light guide where a small fraction of the light is coupled in via a 425nm grating and guided to a sensor at the edge of the cover plate. In this way a single sensor can sample the full area of the RGB-luminaire and control the color non-uniformities.

8835-18, Session 4

Thermal and optical aspects of glob-top design for phosphor converted white LED light sources

Christian Sommer, JOANNEUM RESEARCH Forschungsgesellschaft mbH (Austria); Paul Fulmek, Johann Nicolics, Technische Univ. Wien (Austria); Susanne Schweitzer, Wolfgang Nemitz, Paul Hartmann, JOANNEUM RESEARCH Forschungsgesellschaft mbH (Austria); Peter Pachler, Hans Hoschopf, Franz Schrank, Tridonic Jennersdorf GmbH (Austria); Gregor Langer, Austria Technologie & Systemtechnik AG (Austria); Franz-Peter Wenzl, JOANNEUM RESEARCH Forschungsgesellschaft mbH (Austria)

For a systematic approach to improve the white light quality of phosphor converted light-emitting diodes (LEDs) for general lighting applications it is imperative to get the individual sources of error for color temperature constancy under control. In this regard, it is important to understand how compositional, optical and thermal properties of the color conversion elements (CCE), which typically consist of phosphor particles embedded in a transparent matrix material, affect the constancy of a desired correlated color temperature of a white LED source under operation. In this contribution we use an LED assembly consisting of an LED die mounted on a printed circuit board by chip-on-board technology and a CCE with a glob-top design on the top of it as a model system and discuss the impact of the CCE shape, size and composition on the respective tolerance ranges for color temperature constancy with respect to substrate reflectivity and thermal load of the CCEs. From these studies, some general conclusions of optimized glob-top designs in regard of color temperature constancy of white LED sources under operation can be drawn.

8835-19, Session 4

Object-oriented emission adaptive phosphor layer for pc-white LED

Kwang-Cheol Lee, Deok Gi Kim, So-Ra Gang, Jong Hyeob Baek, Korea Photonics Technology Institute (Korea, Republic of)

Phosphor layer which basically absorbs a part of exciting light and emits the complementary light to white light is necessary for phosphor-converted white LED. Especially, phosphor layer for illumination requests not only high luminous efficiency, robust reliability in performance but also high color-rendering, high angular color homogeneity in quality.

In this study, we manipulated diverse structures into transforming the light emitted from LED chip into the modified emission pattern and made the optical structure from photosensitive resin with this emission pattern. Therefore, this optical structure could realize the object-oriented emission pattern. Phosphor particles could be arranged on the surface of LED chip or in/on the optical structure and combined with others. In conclusion, this emission adaptive phosphor layer could realize high rendering-color, luminous efficiency, angular color homogeneity and form an object-oriented emission pattern.

8835-20, Session 5

Insights into accelerated aging of SSL luminaires

Lynn Davis, RTI International (United States)

The lumen maintenance behavior of SSL luminaires must be addressed at the optical systems level, taking into account the aging characteristics of all components including LEDs, lenses, diffusers, and reflectors. While SSL products are often intended to have product lifetimes of 15 years or more, the rapid change in SSL technology has created a need for accelerated life test that can be performed in the span of several months. The accelerated aging protocols that we have investigated were derived from standard electronics industry tests and consist of variations in temperature, humidity and/or electrical power cycles. Some testing procedures were found to successfully accelerate lumen depreciation by broadly impacting the performance of the optical system including accelerating LED lumen depreciation, decreasing lens transmittance, and reducing housing reflectance. A strong dependence upon both optical material choices and luminaire design was also found. In some designs, LED lumen depreciation accounted for less than half of the total luminaire light loss during testing, with changes in the rest of the optical system dominating. Subtle differences were also found for luminaires using remote phosphor technology compared to those with conventional phosphor-converted LED and hybrid LED configurations. The findings from this study will be reported along with the insights that these tests provide on potential accelerated testing protocols for SSL luminaires. Emphasis will be placed on lumen maintenance as the pass/fail criterion, but color shift, as influenced by aging of the optical system, will also be discussed.

8835-21, Session 5

Prediction of L70 lumen maintenance and chromaticity for LEDs using extended Kalman filter models

Pradeep Lall, Junchao Wei, Auburn Univ. (United States); Lynn Davis, RTI International (United States)

Solid-state lighting (SSL) luminaires containing light emitting diodes (LEDs) have the potential of seeing excessive temperatures when being transported across country or being stored in non-climate controlled warehouses. They are also being used in outdoor applications in desert environments that see little or no humidity but will experience extremely high temperatures during the day. This makes it important to increase the understanding high temperature exposure effects on LEDs. The LEDs continually degrade and the light output decreases eventually below useful levels causing failure. Presently, the TM-21 test standard is used to predict the L70 life of SSL Luminaires from LM-80 test data. The TM-21 model uses an Arrhenius Equation with an Activation Energy, Pre-decay factor and Decay Rates. The underlying TM-21 Arrhenius Model may not capture the failure physics in presence of multiple failure mechanisms. In this paper, Kalman Filter (KF) and Extended Kalman Filters (EKF) have been used to develop a 70-percent Lumen Maintenance Life Prediction Model for a LEDs used in SSL luminaires. Ten-thousand hour LM-80 test data for various LEDs have been used for model development. System state at each future time has been computed based on the state space at preceding time step, system dynamics matrix, control vector, control matrix, measurement matrix, measured vector, process noise and measurement noise. The future state of the lumen depreciation and chromaticity has been estimated based on a second order Kalman Filter model and a Bayesian Framework.

8835-22, Session 5

The impact of different current driving schemes on the thermal load of the color conversion elements in phosphor converted LEDs

Franz-Peter Wenzl, JOANNEUM RESEARCH Forschungsgesellschaft mbH (Austria); Paul Fulmek, Technische Univ. Wien (Austria); Christian Sommer, Paul Hartmann, JOANNEUM RESEARCH Forschungsgesellschaft mbH (Austria); Peter Pachler, Hans Hoschopf, Franz Schrank, TridonicAtco Optoelectronics GmbH (Austria); Gregor Langer, Austria Technologie & Systemtechnik AG (Austria); Johann Nicolics, Technische Univ. Wien (Austria)

Correlated color temperature constancy and correlated color temperature maintenance are key issues in the context of the utilization of light-emitting diodes (LEDs) for general lighting applications. For a systematic improvement, it is imperative to understand how compositional, optical and thermal properties of the color conversion elements (CCE), which typically consist of phosphor particles embedded in a transparent matrix material, affect the constancy of a desired correlated color temperature of a white LED source under operation. In particular, a strong thermal load of the CCEs under operation may cause notable color shifts. By means of a combined optical and thermal simulation procedure, in this contribution we give a comprehensive discussion on the impact of different current driving schemes on the thermal load of the CCEs of phosphor converted LEDs. We show that on the one hand a decreasing duty cycle under pulse width modulation driving conditions may have a notable impact on the thermal load of the CCEs in comparison with DC current driving conditions of the same current amplitude and on the other hand also effects due to the non-linearity between the blue radiant flux and the current have to be considered.

8835-23, Session 5

A driving scheme to reduce AC LED flicker

Jianchuan Tan, Nadarajah Narendran, Rensselaer Polytechnic Institute (United States)

Light flicker is a common but unwelcome phenomenon in conventional lighting applications. In solid-state lighting, driving or dimming methods also give rise to light flicker. AC LED products in today's marketplace suffer from flicker, which stems from the arrangement of the micro-LEDs and the driving method. Research has shown that light flicker can be a health hazard to humans. Several solutions have been proposed to reduce light flicker in solid-state lighting applications; however, most have drawbacks in terms of power and other performance. This paper proposes a circuit design to reduce light flicker from AC LEDs while maintaining a normal power factor and high power efficiency. The circuit is composed of one resistive branch and one capacitive branch, and each branch drives a load which is made up of high-voltage LEDs. Percent flicker, power factor, and power efficiency are selected as three metrics, and their benchmarks are set to evaluate the performance of this circuit. Phase shift between the two branches is selected as a factor that can determine the circuit performance. The variations of percent flicker, power factor, and power efficiency as a function of phase shift are identified by theoretical analysis and are verified by experiments. The experimental results show that an optimal solution can be achieved for this circuit design at proper phase shift, where the benchmarks of the three metrics are reached.

8835-24, Session 6

Luminescence properties of rare earth ions doped glasses excited by broadband lights

Linjiao Ren, Xiaohua Lei, Chongqing Univ. (China); Weimin Chen, Chongqing Univ (China); Xiaoqing Du, Lei Jin, Yong'an Feng, Chongqing Univ. (China)

White LED occupies an important position in solid state lighting area. Compared with commercial white LED, the UV chip-pumped white LED including RGB-emitting luminescent glass performs better color index, thermal stability and so on. In the existing researches, the excitations of rare earth ions (REI) doped luminescent glasses are light source of fluorescence spectrophotometer, which can emit monochromatic lights. But when the glasses were used for white LEDs, the excitation light source is an ultraviolet chip with an emission bandwidth of about 5nm. So the luminescence properties of rare earth ions doped glass excited by broadband lights should be investigated.

Rare earth ions generally have plenty of well-shielded 4f states that can be excited by narrow peaks, such as Tb^{3+} and Eu^{3+}, so the change of excitation wavelength can greatly influence the intensity ratio of blue, green and red emissions which can be reflected in the chromaticity coordinate and CCT. Applying Ce/Tb/Eu co-doped calcium borosilicate glasses as examples, a computational model was presented to simulate the emission spectra of luminescent glasses excited by broadband lights, based on the dependences of excitation wavelengths on emission spectra, chromaticity coordinates and CCTs. The results show that for the same CCTs, the center wavelengths of chips are different with the excitation wavelengths of fluorescence spectrophotometers, which provides guidance to the application of luminescent glasses.

8835-25, Session 6

Characterization of piezoelectric fields in InGaN quantum wells of GaN-based LEDs

Yi-Chin Lin, Cheng-Yi Liu, National Central Univ. (Taiwan)

The net electric field in the InGaN MQWs would greatly affect the lighting efficiency and the optical performance of the GaN-based LED. The built-

in field, polarization field, carrier screening field, and the applied electric field are known to be the major electrical fields in the InGaN multi-quantum wells (MQWs) of the GaN-based LEDs. Among the above four electrical fields, the polarization field is directly related to the epitaxial GaN/InGaN property and epitaxial processes. The polarization field in the InGaN wells includes spontaneous and piezoelectric polarization. The spontaneous polarization comes from the nature of InGaN epitaxial layer. On the contrary, the piezoelectric polarization is caused by both lattice mismatch (LM) and CTE mismatch (thermal stress; TM) between InGaN well layers and GaN barrier layers. In the past, many researchers reported that the magnitude of the LM-induced piezoelectric field is larger than the TM-induced piezoelectric field by one order.

In this talk, we measured the piezoelectric field variation of the GaN-based LED chips die-attached on Cu substrates with different die-attachment processes. With the obtained piezoelectric field values, we found that the TM-induced piezoelectric field is dominant factor over the LM-induced piezoelectric field. The detail approach to define the piezoelectric field and decouple the piezoelectric field and screening field would be presented.

8835-26, Session 6

Monte Carlo simulation of radiation pattern for rare earth ions doped luminescent glasses under violet LED excitation

Xiaohua Lei, Yong'an Feng, Weimin Chen, Peng Zhang, Linjiao Ren, Xiaoqing Du, Chongqing Univ. (China)

Rare earth ions doped luminescence glasses are promising phosphor candidates in the fabrication of LEDs in the future due to their specific advantages, such as higher thermal stability, higher transparency, compared to current commercial LEDs. While radiation patterns of luminescent glasses are different from current commercial LEDs fabricated by phosphors, luminescent glasses play roles both in emitting light and adjusting light distribution. In order to investigate radiation pattern of luminescent glasses, luminescence physical model of flat glasses doped with single rare earth ion was presented. Process of photons acting on rare earth ions and transporting in the luminescent glasses, and output light distribution from luminescent glasses were simulated by Monte Carlo method based on violet LED. At last, the simulating of radiation pattern for luminescent glasses based on Monte Carlo method was proved by experiment.

8835-27, Session 6

Piezoelectric hysteresis effect on GaN-Based LED optical and electrical performance

Chao-Chi Chung, Cheng-Yi Liu, National Central Univ. (Taiwan)

GaN-based compounds are widely utilized in optoelectronic devices, such as light-emitting diode (LED), hetero-junction transistor, and laser diode. GaN-based compounds are piezoelectric materials because of their wurtzite structure. As a result, a piezoelectric field would be produced in GaN-based device structure, which would cause deterioration in the efficiency and carrier mobility of the devices. In this work, we found that the piezoelectric field induced in the GaN-based LED has a hysteresis behavior. The detail mechanism of the hysteresis behavior of the piezoelectric field in the GaN-based LED would be discussed in this talk.

Also, we found that the hysteresis effect in the piezoelectric field in the GaN-based LED would greatly affect the accuracy of the junction-temperature determination. Consequently, the thermal resistance defined by the junction temperature measurement would be a problem. In this talk, we will also discuss the calibration of the junction temperature measurement by considering the hysteresis effect in the piezoelectric field in the GaN-based LED.

8836-33, Session PMon

Optical-field induced volume- and surface-relief formation phenomenon in thin films of vitreous chalcogenide semiconductors

Ugis Gertners, Zanda Alute, Elina Potanina, Janis Teteris, Univ. of Latvia (Latvia)

The demand of lower cost surface-relief based optical instruments such as grating-based resonators or filters for waveguides, diffractometers, spectrometers, etc. is one of the main driving forces for the investigation of direct light-induced relief formation. The most common techniques for fabricating and investigating these surface-relief gratings involve an interferometric or holographic recording setup.

We have investigated that the light-induced mass transfer process strongly depends on the material itself and polarization of the light. The behavior of mass transfer and thus the resulting recording could be related to interaction between the polar photo-induced defects and the polarized electric field of recording beam. It has been shown that the mass transfer can be directed both ways – towards or away from the electric field intensity gradient. The evolution of surface relief in dependence from the recording time and polarization has been investigated in detail. The mechanism of the direct recording of surface relief on amorphous chalcogenide films based on the photo-induced plasticity has been discussed.

A direct recording technique is a comparatively new solution for lithography and, as shown in this report, provides new experimental techniques for better understanding of the interaction between the light and matter. The obtained gratings are very stable at room temperature, so this method can replace some of the chemical etching techniques and find a practical application in the applied physics.

A conceptual design for a Cassegrain-mounted high-resolution optical spectrograph for large-aperture telescopes

Cynthia S. Froning, Steven Osterman, Univ. of Colorado at Boulder (United States); Eric Burgh, NASA Ames Research Ctr. (United States); Matthew Beasley, Planetary Resources, Inc. (United States); Paul Scowen, Arizona State Univ. (United States); Todd Veach, NASA Goddard Space Flight Ctr. (United States); Michael Lieber, Steven Jordan, Dennis Ebbets, James deCino, Ball Aerospace & Technologies Corp. (United States); Bruno Castilho, Cesar Oliveira, Lab. Nacional de Astrofísica (Brazil)

We present a conceptual design for a high resolution optical spectrograph appropriate for mounting at Cassegrain on a large aperture telescope. The design is based on our work on the Gemini High Resolution Optical Spectrograph (GHOS) project. Our design places the spectrograph at Cassegrain to maximize throughput and blue wavelength coverage, achieving R~40,000 resolving power over a simultaneous 320-1050 nm waveband with throughputs twice those of comparable instruments. The optical design use a two-arm, cross-dispersed echelle format with each arm optimized to maximize throughput. A fixed image slicer is used to minimize optics sizes. The principal challenge for the instrument is to minimize instrument flexure and degradation of the optical image. To ensure image stability, our opto-mechanical design combines a cost-effective, passively stable bench employing a honeycomb aluminum structure with active flexure control. The active flexure compensation consists of hexapod mounts for each focal plane with full 6-axis range of motion capability to correct for focus and beam displacement. We verified instrument performance using an integrated model that couples the optical and mechanical design to predict image performance. Our full end-to-end modeling of the system under gravitational, thermal, and vibrational perturbations shows that deflections of the optical beam at the focal plane are <29 µm per exposure under the worst case scenario (<10 µm for most orientations), with final correction to 5 µm or better using open-loop active correction to meet the stability requirement. Finally, we will discuss applications of our design and high fidelity modeling process to future instruments.

8836-35, Session PMon

Opto-mechanical analysis for 1-meter astronomical telescope

Kwijong Park, Jeong-Gyun Jang, Inwoo Han, Bi-Ho Jang, Dae-Hee Lee, Korea Astronomy and Space Science Institute (Korea, Republic of)

We developed the precise finite element model of an 1-meter telescope through auto or manual mesh generation. For gravity and temperature change, stress and displacement of the overall structure, and performance of mirror surface were analyzed.

8836-36, Session PMon

Radial in-plane electronic speckle pattern interferometry with divergent illumination

Jorge R. Parra Michel, Rafael Hernández Román, Univ. De La Salle Bajío (Mexico); Amalia Martínez García, Ctr. de Investigaciones en Óptica, A.C. (Mexico)

Interferometry electronic speckle pattern (ESPI) is a very useful technique for deformation measurement of surfaces on mechanical elements. The illumination sources can be collimated or divergent, this last one, considering some approaches, adjustments and corrections in theoretical models in comparison with collimated illumination due the spherical wave front. The directions of deformation measurements is a function of the sensibility vector of the optical system used for this purpose, and are common measurements in orthogonal directions in the Cartesian coordinate system. In recent years a radial in-plane ESPI interferometer using conical mirrors, beam splitters and collimated illumination was proposed. The configuration of the optical system set up can be simplified considerably if we consider positioning a divergent illumination and a CCD camera near to the center of the optical axis. However, we must be very careful when considering these approaches in theoretical and mathematical models when performing measurements. The divergent illumination near to the analyzed surface carries an unacceptable error in measurements. In this paper, a radial-in-plane ESPI with divergent illumination and conical mirrors are analyzed for radial deformation measurements. The contribution of the sensibility vectors and an algorithm to correct errors due to the spherical wave front are presented too. Also, we show an example of strain hole-fields measurements in the radial direction around a crack tip in a plate when it is under tension loads.

8836-1, Session 1

The correct lens mount lightweighting and stress OPD analysis in Cassegrain telescope

Ming-Ying Hsu, Instrument Technology Research Ctr. (Taiwan)

This article is discussing the correct lens assembly different mount barrels material in thermal cycle condition optical performance analysis. The system mass budget allocated to correct lens assembly was 5 Kg. Meanwhile, according with optical design the correct lens was made by fused silica, the lens diameter was 130 mm, and the mass was 2.3 Kg. Therefore, remain mass budget was 2.7 Kg; include the lens mount, spacer, mount barrel and retainer. The mount barrel material is made by invar. If the barrel materials are change to the titanium or aluminum, the mount barrel weight will decline 42% and 63% respectively. The surrounding temperature difference will affect mount barrels deformation, and cause lens deformation and stress Optical Path Difference (OPD). Thus, the off-axis ray path of the stress OPD calculation, must consider lens incidence point and emergence point. The correct lens deformation and stress in different thermal condition are solving by Finite Element Method (FEM) software. The stress calculation results can be weighting to each incidence ray path and calculate stress OPD. Meanwhile, the correct lens deformation on Z-direction can be fitted by rigid body motion and Zernike polynomial. The stress OPD and correct lens deformation fitting results can be used to evaluate the barrel material different, effect on correct lens assembly in telescope system.

8836-2, Session 1

The ASTRI SST-2M prototype: camera design

Vincenzo De Caprio, INAF - Osservatorio Astronomico di Brera (Italy); Massimiliano Belluso, INAF - Osservatorio Astrofisico di Catania (Italy); Giuseppe Sottile, Giovanni La Rosa, Osvaldo Catalano, INAF - IASF Palermo (Italy)

The Cherenkov Telescope Array (CTA) is the next generation ground-based very high-energy (VHE) gamma-ray instrument that will explore our Universe above 10 GeV. The ASTRI (Astrofisica con Specchi a Tecnologia Replicante Italiana) “Flagship Project”, financed by the Italian Ministry of Education, University and Research (MIUR) and lead by the Italian National Institute of Astrophysics (INAF), is the Italian contribution to the CTA, supporting all activities related to the finalization of the CTA technological aspects. The main goal of the Project is the realization of a prototype Cherenkov Small-Size Telescope in double mirror configuration (ASTRI SST-2M) equipped with a detection Camera based on silicon devices of the SiPM type (made by HAMAMATSU). The technological solution adopted for the Camera is based on a focal plane detector consisting of a 37 SiPM sensors, to adapt the focal plane on a curved surface, as imposed by the optical design. Such a level of modularity is mandatory in order to fit as much as possible the required focal surface curvature. We provide in this paper an overview of the mechanical, thermal and electrical concept design of the Camera.

8836-3, Session 1

Design considerations in a novel fiber-coupled three degree-of-freedom displacement interferometer

Steven R. Gillmer, Jonathan D. Ellis, Univ. of Rochester (United States)

Heterodyne displacement interferometry is a widely accepted methodology capable of measuring displacements with sub-nanometer resolution. The objective of this research is to demonstrate a compact, fiber-delivered displacement measuring interferometer which can be used to simultaneously calibrate the linear motion and rotational errors of a translating stage using a single measurement beam. This novel interferometer utilizes differential wavefront sensing to measure target mirror displacement, and changes in pitch and yaw. Differential wavefront sensing uses a quadrant photodiode to measure four spatially separated interference signals within a single optical interference beam. Based on the geometry of the detector and the interference phase in each quadrant, the displacement and changes in target pitch and yaw can be measured.

The opto-mechanical design of a working prototype has yielded an instrument with a 90 mm x 100 mm x 50 mm (3.5 in. x 4 in. x 2 in.) footprint. Thermal deformations have been mitigated through the implementation of kinematic mounting. The Invar optical support structure of the interferometer is kinematically mounted to the stainless steel base to ensure that free expansion occurs away from a thermal datum which is coplanar to the reference mirror. As a result, the same thermal expansion is seen in the reference and measurement arms of the interferometer and thus cancel out. A linearized finite element stress analysis has been conducted on the Invar optical support structure in addition to the custom stainless steel squeeze clamps which house launch fiber collimators. Design considerations and preliminary testing of the working prototype will be presented.

8836-4, Session 1

Remote vibration sensor using fiber optic fused 2x2 coupler

Dinkar Dantala, Kishore Putha, Srimannarayana Kamineni, Vengal Rao Pachava, National Institute of Technology, Warangal (India)

A simple fiber optic vibration sensor is designed using 2x2 multimode fiber optic coupler , based on the principle of reflection intensity modulation. An LED (650 nm) is used as source and high sensitivity photo-Darlington (PD) as detector to detect the modulated light intensity corresponding to the vibration of the object. A Simple detection circuit (to convert the modulated light intensity into its equivalent voltage signal and NI-DAQ with Lab VIEW software) is used to record the time domain signal (TDS) of the vibrator. By using Fast Fourier transform (FFT), the frequency and amplitude of vibrations are measured from TDS. The optical coupler with 80:20 splitting ratio is used in the design of sensor, that is made of multimode PMMA fiber with core/cladding diameters of about 980/1000 µm and is length of 100 cm. The light is coupled to the port A, will be split into (80:20) and part of the light is transmitted through the port C which act as a sensing probe and the other part is directed to PD1 through port D ,used as a reference probe. The light from port C is projects onto the vibrating object then the modulated reflected light is traced by the same port and directed to the PD2 through port B. The rational output of PD1 and PD2 avoids the effect of source signal power fluctuations and fiber bending loss. The calibrated 1mm linear region of the characteristic displacement curve is used to measure the amplitude of vibrations. High sensitivity vibration measurements are observed within the linear region of the characteristic displacement curve. The experimental results show that the sensor is capable of measure the frequency up to 3500 Hz with ~0.03µm resolution of vibration amplitude over a dynamic range of 0-1mm. The SNR (Signal to Noise Ratio) of the signal is also increased by the rational output with respect to the reference and sensing signals. In comparison with dual-fiber and bifurcated-bundle fiber, this sensor eliminates the dark region and front slope which facilitates the easy alignment. The simplicity of design, non-contact measurement, high degree of sensitivity, economical along with advantages of fiber optic sensors are attractive attributes of the designed sensor that lend support to real time monitoring and embedded applications.

8836-5, Session 1

Raytheon high-bandwidth large-angle and reactionless fast steering mirror

Islam Shawki, Raytheon Co. (United States); Andrew Bullard, Raytheon Space & Airborne Systems (United States)

Raytheon Space and Airborne Systems (SAS) has designed, built and tested a 3-inch diameter fast steering mirror (FSM) for space application. This 2-axis FSM operates over a large angle, has a very high servo bandwidth, has very low noise, and has microradian class line of sight accuracy. The FSM maintains excellent performance over large temperature ranges and has very high reliability with the help of fully redundant position sensors and actuator circuits. Additionally, the FSM is also reaction-compensated. The FSM has undergone extensive testing which include characterization of exported forces and torques and thermal vacuum testing.

8836-6, Session 2

Practical aspects of specification of extreme lightweight ZERODUR(R) mirrors for spaceborne missions *(Invited Paper)*

Tony Hull, The Univ. of New Mexico (United States) and SCHOTT North America, Inc. (United States); Thomas Westerhoff, Ralf Jedamzik, Antoine Lays, SCHOTT AG (Germany); Todd Jaeger, SCHOTT North America, Inc. (United States); John Pepi, L-3 Communications IOS-SSG (United States)

Attributes of Extreme Lightweight ZERODUR® Mirrors have been analyzed and described in our recent series of papers, and demonstrated in the form of Schott's representative 1.2m diameter mirror (88% isogrid lightweighted with f0>200Hz), which has been exhibited at the 2013 American Astronomical Society Winter Meeting, and SPIE's 2013 Photonic West. Not only are the attributes of this mirror material and mirror substrate design suitable for spaceflight, the manufacturing approach is compatible with attractive mirror substrate cost and delivery schedules. We will review recent data on the low magnitude and homogeneity of the coefficient of thermal expansion, and on the toughness of the material. This approach to mirror substrate design is compatible with mirror sizes from less than 0.5m to greater than 4m across. Round, hexagonal, elliptical and square mirrors are all compatible with this mirror approach. In this paper, we describe the basic substrate manufacturing approach, and discuss various trades available to the telescope architect. We will also list principal customer-specified parameters which are sufficient for Schott to provide design-for-manufacturability, optimized for either low cost or low mass. In this manner, the end user can efficiently obtain an optimized mirror without detailed knowledge of the manufacturing process.

8836-7, Session 2

Advanced composite materials for optomechanical systems

Carl H. Zweben, Zweben Consulting (United States)

The four classes of composites are now well established optomechanical system materials. They are: polymer matrix composites (PMCs), metal matrix composites (MMCs), ceramic matrix composites (CMCs), and carbon matrix composites (CAMCs). The latter include carbon/carbon composites (CCCs). The success of composites has resulted in increasing use in consumer, industrial, scientific, and aerospace/defense optomechanical applications. They offer significant advantages over traditional materials including high stiffnesses and strengths, near-zero and tailorable coefficients of thermal expansion, tailorable thermal conductivities (from very low to much higher than copper), and low densities. Some manufacturing processes allow parts consolidation and reduce machining requirements. PMCs are the most widely used composites. Optomechanical applications date from the 1970s. For example, the High-Energy Astronomical Observatory (HEAO-2) spacecraft, launched in 1978, had an ultrahigh modulus carbon fiber-reinforced epoxy optical bench. Since then, both fibers and matrix materials have advanced significantly, and use of carbon fiber-reinforced polymers (CFRPs) has increased steadily. Space system examples include the Hubble Space Telescope, AXAF, UARS, James Webb Space Telescope and many others. Use has spread to many other airborne applications, such as the airborne SOFIA. Perhaps the most impressive CFRP applications are the fifty-four 12m and twelve 7m moveable ground-based ALMA antennas. The other three classes of composites have significant advantages over PMCs, including no moisture absorption/desorption or outgassing of organic compounds. CCC and CMC components have flown on a variety of spacecraft. MMCs have been used in space, aircraft and industrial applications. In this paper, we review key PMC, MMC, CAMC, and CMC optomechanical system materials, including properties, advantages, disadvantages, applications and future developments.

8836-8, Session 2

Design guidelines for high-dimensional stability of CFRP optical bench

Nichola Desnoyers, Marc-André Boucher, Philippe Goyette, INO (Canada)

In carbon fiber reinforced plastic (CFRP) optomechanical structures, particularly when embodying reflective optics, angular stability is critical. Angular stability or warping stability is greatly affected by moisture absorption and thermal gradients. Unfortunately, it is impossible to achieve the perfect laminate and there will always be manufacturing errors in trying to reach a quasi-iso laminate. Some errors, such as those related to the angular position of each ply and the skin parallelism (for a bench) can be easily monitored in order to control the stability more adequately.

This paper presents warping experiments and finite-element analyses (FEA) obtained from typical optomechanical sandwich structures. Experiments were done using a thermal vacuum chamber cycling the structures from -40°C to 50°C. Moisture desorption tests were also performed for some specific configurations. The selected composite material for the study is the unidirectional prepreg from Tencate M55J/TC410. M55J is a high modulus fiber and TC410 is a new-generation cyanate ester designed for dimensionally stable optical benches. In the studied cases, the main contributors were found to be: the ply angular errors, laminate parallelism, fiber volume fraction tolerance and joints. Final results show that some tested configurations demonstrate good warping stability. FEA and measurements are in good agreement despite the fact that some defects or fabrication errors remain unpredictable. Design guidelines to maximize the warping stability by taking into account the main dimensional stability contributors, the bench geometry and the optical mount interface are then proposed.

8836-9, Session 2

On the strength of glass

Alson E. Hatheway, Alson E. Hatheway Inc. (United States)

Glass has been ignored by most of the structural engineering community because of its brittle nature. Glass is an indispensable material in optical systems and sometimes safety, even human safety, depends upon optical glass elements that behave in a structurally reliable manner. One such occasion is to accommodate survey cameras in transport-class aircraft. Fortunately, glass has reliable structural properties and the methods for structural analysis and testing for glass have been well developed. Unfortunately, the glass suppliers have not chosen to publish the appropriate strength properties for many of their glasses. This paper describes the physics of the strength of glass and the engineering application of that physics to an airborne survey aircraft for the safety of its inhabitants.

8836-10, Session 3

Alignment and assembly strategies for AWARE-10 gigapixel-scale cameras

Hui S. Son, Daniel L. Marks, Seo H. Youn, David J. Brady, Jungsang Kim, Duke Univ. (United States)

Gigapixel cameras using lens arrays can contain hundreds to thousands of precisely positioned optical components and thus require fast, reliable methods for optical assembly and alignment verification. Our first one-gigapixel prototype camera (AWARE-2) and our four-gigapixel camera currently under development (AWARE-10) need active alignment and performance measurement procedures during assembly to ensure high quality images. Here we describe the methods that we have developed to ensure proper positioning of all optical components in the AWARE-10 system and the resulting optomechanical design decisions. AWARE cameras employ a single monocentric objective lens that is

shared by an array of smaller "micro-cameras", each composed of a set of smaller scale lenses. In AWARE-10, approximately two thousand pieces of individual optics must be aligned to a high level of accuracy in order to attain the desired optical resolution over four gigapixels. To guarantee proper alignment before final assembly, the objective lens and the micro-optics are checked separately. Using tools including autostigmatic microscopy, slanted edge MTF measurements, and flat field measurements, we can confirm the correct alignment of individual components before assembly. Optomechanical designs that incorporate the application of these alignment tools are described.

8836-11, Session 3

Development of a wide-field telescope

Il K. Moon, Sangon Lee, Korea Research Institute of Standards and Science (Korea, Republic of); Juhee Lim, Kyung Hee Univ. (Korea, Republic of); Hyug-Gyo Rhee, Ho Soon Yang, Yun Woo Lee, Korea Research Institute of Standards and Science (Korea, Republic of); Jong Ung Lee, Cheongju Univ. (Korea, Republic of)

A prototype of large wide field telescope is a Cassegrain telescope which covers 2° field of view with two hyperbolic mirrors, a 0.5 m primary mirror and a 0.2 m secondary mirror with multiple correction lenses. Optimization of telescope has been conducted with various opto-mechanical analyses under gravity, temperature and dynamic loads by using finite element analyses. Optical performance evaluation and image motion are also calculated based on line of sight sensitivity equations integrated in finite element models. Manufacturing of optical elements and structure and alignment, install and test observation of a wide field telescope will be discussed.

8836-12, Session 3

High-sensitive FBG pressure sensor using metal bellows

Vengalrao Pachava, Srimannarayana K., Sai Shankar M., Kishore P., National Institute of Technology, Warangal (India)

A fiber-optic sensor scheme, capable of the simultaneous measurement of pressure and temperature using two in-line Fiber Bragg Gratings (FBGs) is reported. Sensor head is configured by embedding the two FBGs with metal bellows, such that FBG1 is sensitive to both pressure and temperature, whereas the FBG2 is only sensitive to temperature being shielded from external pressure. High pressure sensitivity is achieved due to lower spring rate in longitudinal direction to that of the large elastic modulus in transverse direction of the metal bellows. Pressure and temperature measurement is made by monitoring the shift of Bragg resonance wavelengths of the FBGs corresponds to variation in applied pressure and temperature. From the test results the obtained pressure and temperature sensitivities are 86 pm/psi and 9.1 pm/°C, over a dynamic range of 0-40 psi pressure, and 25-110°C temperature measurements respectively. The experimental results well agreed with the theoretical results and show good linearity. This simple design, economical and all fiber optic sensor can be used for liquid and gas pressure measurements, and under-water applications.

8836-13, Session 4

Optomechanical analysis of mirror mounting mechanism

Chen Ching-Wei, Chia-Ray Chen, National Space Organization (Taiwan); Po-Hsuan Huang, Chia-Yen Chan, Instrument Technology Research Ctr. (Taiwan)

This paper is investigated to construct the self-developed fundamental capability which can apply to the opto-mechanical design and analysis in space telescope. The mounting mechanics is found to be a key issue to dramatically affect the optical performance in optical systems. Design and experiments are conducted to study the relationship between stress and wavefront error of the opto-mechanical systems by use of the interferometric measurement. Zernike polynomials and wavefront fitting is performed to study the mirror mounting mechanism. It is reported that mirror mounting stress will severely affect the wavefront errors of the optical system. Especially, the experimental results show that the unbalanced stress will increase the wavefront errors, especially in the terms of astigmatism and trefoil. In addition, the external transverse shear stress will also degrade the astigmatism aberration.

8836-14, Session 4

On the statistical distribution of optical parameters in manufactured systems

Morris I. Kaufman, National Security Technologies, LLC (United States); Brandon B. Light, Optimax Systems, Inc. (United States); Robert M. Malone, Daniel K. Frayer, National Security Technologies, LLC (United States)

Generating optical tolerances in software systems such as Code V or Zemax usually begins by modeling a perturbed optical system to capture the effect of simultaneous changes in lens radius, center thickness, and other critical parameters. The analyst would assume a statistical distribution of the relevant parameters for the Monte Carlo simulation. Unfortunately, the assumed distributions generally do not resemble the real distributions that occur in lens manufacturing. For example optical designers will typically assume that the distribution is symmetric about their chosen nominal value, but in many cases this assumption is predictably false. They might also assume that the distribution will be zero, or nearly zero, at the tolerance limits, and this, too, is often wrong. Obviously, the best option would be to have actual manufacturing data to inform our selection of a statistical distribution in a Monte Carlo simulation. Understanding these distributions will have other beneficial consequences. The designer (or manufacturer) could easily predict the cost of changing a particular tolerance (as a result of lost yield) for a given manufacturing process. The factors that influence these distributions are revealing. For example, short runs will have different distributions than long runs where the manufacturing process is mature. We will present manufacturing data and supporting analysis to help optical designers make more rational choices during the tolerancing process.

8836-15, Session 4

Next-generation lightweight mirror modeling software

William R. Arnold Sr., Jacobs Engineering Group Inc. (United States); Matthew Fitzgerald, Univ. of Illinois at Urbana-Champaign (United States); H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States)

The advances in manufacturing techniques for lightweight mirrors, such as EXELSIS deep core low temperature fusion, Corning's continued improvements in the Frit bonding process and the ability to cast large complex designs, combined with water-jet and conventional diamond machining of glasses and ceramics has created the need for more efficient means of generating finite element models of these structures. Traditional methods of assembling 400,000 + element models can take weeks of effort, severely limiting the range of possible optimization variables. This paper will introduce model generation software developed under NASA sponsorship for the design of both terrestrial and space based mirrors. The software deals with any current mirror manufacturing technique, single substrates, multiple arrays of substrates, as well as the ability to merge submodels into a single large model. The modeler generates both mirror and suspension system elements, suspensions can be created either for each individual petal or the whole mirror. A typical model generation of 250,000 nodes and 450,000 elements only takes

5-10 minutes, much of that time being variable input time. The program can create input decks for ANSYS, ABAQUS and NASTRAN. An archive/retrieval system permits creation of complete trade studies, varying cell size, depth, and petal size, suspension geometry with the ability to recall a particular set of parameters and make small or large changes with ease.

The input decks created by the modeler are text files which can be modified by any editor, all the key shell thickness parameters are accessible and comments in deck identify which groups of elements are associated with these parameters. This again makes optimization easier. With ANSYS decks, the nodes representing support attachments are grouped into components; in ABAQUS these are SETS and in NASTRAN as GRIDPOINT SETS, this make integration of these models into large telescope or satellite models possible.

8836-16, Session 4

Thermal analysis of optical mount for cockpit display systems

Shravan Kumar, Vinod Karar, T. K. Jindal, Rakesh Kumar, Central Scientific Instruments Organisation (India)

This paper offers guidance to optomechanical designers on the safe mounting of glass lenses using elastomers. Elastomeric mounting isolates the lenses from strains, deflection, decentration and minimizes the thermal stresses build up with in the opto-mechanical components that is caused by differential radial expansion or contraction of the lenses, cell & elastomer under temperature changes. In this study various types of glasses being used for lens are SK14, SK15 and SF56A and Aluminium alloy 6061 for mechanical components like spacers, clamp, cell etc. The thermal loads being applied are of four types i.e. high temp storage cum operation(35 degrees C to 90 degrees C), low temp. storage(-55 degrees C), low temp. operating (-40 degrees C)and thermal shock(+70 degrees C to -40 degrees C). During FEA analysis, a model of the structure is created with three dimensional continuum of small elements and the elements being used in this study are tetrahedral elements. The modeling of the lens mount is performed by using solid works design tool and detailed finite element analysis (FEA) is performed by using COSMOS. The annular thickness of elastomer is optimized for minimum thermal stresses. The thermal stresses developed are very low and which are not affecting the optical performance of the system. It is witnessed that the analysis results and actual thermal test results are almost matching. The lens mounts designed and developed were qualified the thermal tests and are being used in cockpit display systems. Hence the results of the this paper are helpful to opto-mechanical designers for building up of stress free lens mounts required for cockpit display systems applications.

8836-17, Session 4

Integration of mirror design with suspension system using NASA's new mirror modeling software

William R. Arnold Sr., Jacobs Engineering Group Inc. (United States); Ryan M. Bevan, NASA Marshall Space Flight Ctr. (United States)

Advances in mirror fabrication is making very large space based telescopes possible. In the many applications, only monolithic mirrors meet the performance requirements. The existing and near-term planned heavy launch vehicles place a premium on lowest possible mass. Again, available and planned payload shroud size limits near term designs to 4 meter class mirror. Practical 8 meter and beyond designs could encourage planners to include larger shrouds if it can be proven that such mirrors can be manufactured. These two factors lower mass and larger mirrors, presents the classic optimization problem. There is a practical upper limit to how large a mirror can be supported by a purely kinematic mount system and be launched. This paper shows how the design of the suspension system and mirror blank needs to be designed simultaneously. We will also explore the concepts of auxiliary support systems, which act only during launch and disengage on orbit. We will define required characteristics of these systems and show how they can substantially reduce the mirror mass.

The AMTD project is developing and maturing the processes for future replacements for HUBBLE, creating the design tools, validating the methods and techniques necessary to manufacture, test and launch extremely large optical missions.

This paper will use the AMTD 4 meter "design point" as an illustration of the typical use of the modeler in generating the multiple models of mirror and suspension systems used during the conceptual design phase of most projects. The influence of Hexapod geometry, mirror depth, cell size and construction techniques (Exelsis Deep Core Low Temperature Fusion © versus Corning Frit Bonded © versus Schott Pocket Milled Zerodur © in this particular study) are being evaluated. Due to space and time consideration we will only be able to present snippets of the study in this paper.

8836-18, Session 4

Line-of-sight stabilization by inertial reaction

Allie M. Baker, Goodrich ISR Systems (United States)

A new concept for stabilization of a line-of-sight through the use of the reaction between two intertial members is introduced. This concept includes a mechanical kernel that will provide an immediate real-time correction for platform rotational movement about a single axis. This theoretical approach uses the Euler-Lagrange dynamics equations for its derivation as a problem in classical mechanics.

8836-19, Session 5

Design and analysis of isostatic mounts on a spaceborne lightweight primary mirror

Chia-Yen Chan, Instrument Technology Research Ctr. (Taiwan); Yi-Cheng Chen, National Central Univ. (Taiwan); Shenq-Tsong Chang, Ting-Ming Huang, Ming-Ying Hsu, Instrument Technology Research Ctr. (Taiwan)

The paper is aimed at obtaining the optimum isostatic mount configuration for a ZERODUR® primary mirror with a pre-designed lightweight configuration on the back for a space Cassegrain telescope. The finite element analysis and Zernike polynomial fitting based on the Taguchi method are applied to the whole optimization process. Under the integrated optomechanical analysis, three isostatic mounts are bonded to the center of gravity of the mirror. Geometrical control factors and levels have been selected to minimize the optical aberrations under self-weight loading. Therefore, the primary reflective mirror has been assembled with isostatic mounts of various geometry and different rigid design. The optimum isostatic mount with the least induced astigmatism value is finally attained under the Taguchi method.

8836-20, Session 5

Flexure-mounted spaceflight laser for high g-load launch environment

Viatcheslav Litvinovitch, Joel Edelman, Fibertek, Inc. (United States)

Launching a precision optical instrument, such as a laser, into space presents a challenge due to the harsh structural and acoustic coupled loads that result from the launch vehicle engines. Special precautions must be implemented to protect the payload and attenuate the high frequency random vibration environment while still maintaining accurate alignment and beam pointing. Fibertek has designed, analyzed, and

tested novel Ti6Al4V flexures for isolating a space laser from a high g-load random vibration launch environment. Detailed finite element analysis was done to verify structural integrity of flight hardware by assessing the applied loads, load paths, and critical failure modes. Experimental data validated the modeling and the overall conclusions.

8836-21, Session 5

Optomechanical tolerancing and lens alignment using elastomeric lens mount to efficiently meet optical requirements

Frederic Lamontagne, Michel Doucet, Maxime Savard, Min Wang, INO (Canada)

Lens positioning accuracy and manufacturing cost are two main concerns for optomechanical engineers looking for solutions to reduce costs while meeting stringent optical and environmental requirements. Minimizing optical component positioning errors generally translates into significant cost increases. To maximize the precision-to-cost ratio, there are significant advantages in having both an accurate optomechanical tolerance calculation method and an effective technique to mount and align lenses.

This paper presents a tool that has been developed at INO to easily perform complex optomechanical statistical tolerancing using Monte Carlo simulation to reduce manufacturing and alignment costs. This tolerancing method provides a more realistic prediction of optical component errors compared to the classical worst case and root sum square calculations. In addition, precision alignment using elastomeric lens mounting is presented. Thermal stability and often overlooked factors for effective alignments are discussed. Results of tests performed on real optical assemblies are presented for tolerancing, thermal stability and alignment performance. The use of these methods can considerably reduce cost while efficiently ensuring compliance with requirements.

8836-22, Session 5

A unique mounting for miniature optics at cryogenic temperatures

Zachary N. Leahy, Andrew Magner, ITT Communications Systems (United States)

This paper highlights a mounting solution for miniature, high aspect ratio Zinc Selenide optics capable of sustaining high vibration loads and cryogenic temperatures. The GOES ABI Instrument optical design requires ZnSe filters that have a significantly higher than standard aspect ratio. The thin structure, along with the material properties of ZnSe lead to a filter that is very delicate. The mounting technique minimizes stresses induced over thermal extremes while maintaining sufficient preload for ambient launch loads.

The filters are mounted to metallic housings using a spring loaded retainer and compliant meterials. Detailed analysis of the mounting and an understanding of the unique material properties enables the design to be successful. Special attention is given to materials passing through glass transition temperatures.

This design was qualified through extensive thermal cycling and vibration testing and exhibited performance acceptable for production.

8836-23, Session 5

Optomechanical design of a modular K-B mirror mount system for x-ray microfocusing at the Advanced Photon Source

Deming Shu, R. Harder, Jonathan Almer, Naresh Kujala, Argonne National Lab. (United States); S. Kearney, J. Anton, Argonne National Lab (United States) and Univ. of Illinois at Chicago (United States); Wenjun Liu, Barry Lai, Jörg Maser, Lydia Finney, Bing Shi, Jun Qian, Shashidhara Marathe, Albert Macrander, Jonathan Z. Tischler, Stefan Vogt, Lahsen Assoufid, Argonne National Lab. (United States)

The Kirkpatrick-Baez (K-B) mirrors are sophisticated x-ray micro- and nano-focusing tools for synchrotron radiation applications. A prototype of a modular x-ray K-B mirror mount system has been designed and tested at an optics testing beamline, 1-BM at the Advanced Photon Source (APS), Argonne National Laboratory (ANL). This compact, cost-effective modular mirror mount system is designed to meet challenging mechanical and optical specifications for producing high positioning resolution and stability for various scientific applications with focused hard x-ray beams down to 100-nanometer scale.

The optomechanical design of the modular x-ray K-B mirror mount system as well as the preliminary test results of its precision positioning performance are presented in this paper.

8836-24, Session 6

An athermal mounting of optics in metallic housings

Zachary N. Leahy, Andrew Magner, ITT Communications Systems (United States)

This paper illustrates a unique mounting for a Zinc Selenide optic in an AlBeMet housing for use at cryogenic temperatures. The GOES-R ABI instrument IR beamsplitter design successfully overcomes the significant delta in the coefficient of thermal expansion between the housing and the optic, and the brittle nature of the optic material. The high discrepancy in CTE is exacerbated by a large thermal range experienced between ambient assembly and cryogenic operation.

An athermal packaging of the optics and its bonded clips within a space constrained envelope controls stress over the wide temperature extremes. The opto-mechanical design is capable of maintaining optical alignment after exposure to high-G vibration inputs. Comprehensive testing qualified the design for production.

8836-25, Session 6

Design and measurement of bipod flexure mounts for the IRIS spectrometer

Isaac Weingrod, Catherine Chou, Obert F. Lindstrom, Frank P. Lopez, Howard C. Holmes, Craig L. Hom, J. Wes Irwin, David M. Stubbs, Jean-Pierre Wüelser, Lockheed Martin Space Systems Co. (United States)

The Interface Region Imaging Spectrograph (IRIS) is a NASA SMall EXplorer mission scheduled for launch in 2013. The spacecraft was designed and built at the Lockheed Martin Space Systems Company (LMSSC) in Sunnyvale, CA while the instrument was provided by the LMSSC Advanced Technology Center in Palo Alto, CA. The primary mission goal is to learn how the solar atmosphere is energized. IRIS will obtain UV spectra and images with high resolution in space (0.4 arcsec) and time (1s), focusing on the chromosphere and transition region of our sun, which is a complex interface region between the photosphere and corona. The IRIS instrument uses a Cassegrain telescope to feed a dual spectrograph and slit-jaw imager, which operate in the 133-141 nm and 278-283 nm range.

Within the spectrograph, there are sixteen optics, each requiring subtle mounting features to meet an exacting 5 nm RMS surface figure requirement. This paper covers the entire optomechanical design process for the most challenging optic mounts which include the Collimator, UV Fold Mirrors, and UV Gratings. Although all mounts are unique in size and shape, the fundamental design remains the same. The mounts

are highly kinematic, thermally matched, and independent of friction. Their development will be described in detail, starting with the driving requirements and an explanation of the underlying design philosophy. Next, the key design features and critical analyses are presented, finishing with a review of the test results.

8836-26, Session 6

Development of rotating prism mechanism and athermalized prism mounting for space

Chip R. Beebe, Mark J. Brooks, Michael W. Davis, Robert A. Klar, John M. Roberts, Peter W. A. Roming, Randall J. Rose, Gregory S. Winters, Southwest Research Institute (United States)

Space and launch environments demand robust, low mass, and thermally insensitive mechanisms and optical mount designs. The rotating prism mechanism (RPM), a component of the stabilized dispersive focal plane system (SDFPS), is a spectral disperser mechanism that enables the SDFPS to deliver spectroscopic or direct imaging functionality using only a single optical path. The RPM is a redundant, vacuum-compatible, self-indexing, motorized mechanism that provides robust, athermalized prism mounting for two sets of matching prisms. Each set is composed of a BK7 and a CaF2 prism, both 70 mm in diameter. With the prism sets separated by 1 mm, the RPM rotates the two sets relative to one another over a 180° range, and maintains their alignment over a wide temperature range (190–308°K). The RPM design incorporates self-indexing and backlash prevention features as well as redundant motors, bearings, and gear trains. The RPM was functionally tested in a thermal vacuum chamber at 210°K and <1.0x10-5 Torr, and employed in the top-level SDFPS system testing. This paper presents the mechanical design, analysis, alignment measurements, and test results from the prototype RPM development effort.

8836-27, Session 7

Test-validated alignment and stability performance of the JMAPS program focal plane array assembly in a cryogenic vacuum environment

Brian Thompson, Pedro Sevilla, Michael Watson, Trent Newswander, Duane Miles, James Peterson, Space Dynamics Lab. (United States)

Focal Plane Arrays (FPA) consisting of multiple Sensor Chip Assemblies (SCA) in a precision aligned mosaic are being increasingly used in optical instruments requiring large format detectors. The Joint Milli-Arcsecond Pathfinder Survey Mission (JMAPS) requires very precise positional alignment and stability of its 2 x 2 SCA mosaic at operational temperatures in order to meet its precision sky mapping mission requirements. Key performance requirements include: detector active area co-planarity, in-plane alignment and thermal stability. This paper presents an overview of the JMAPS Focal Plane Array Assembly, its alignment and thermal-mechanical stability requirements and associated test-validated performance in a cryogenic vacuum environment.

8836-29, Session 7

Implementing stray-light baffles for improved JWST NIRCam performance

Paul V. Mammini, Paul Dineen, Alison Nordt, Michael Jacoby, Craig L. Hom, Rob Shivitz, Tom Birge, Lockheed Martin Space Systems Co. (United States)

The Near Infrared Camera (NIRCam) instrument for NASA's James Webb Space Telescope (JWST) has an optical prescription which terminates at two focal plane arrays for each module. The instrument will operate at 37K after experiencing launch loads at ~293K and the focal plane array housings, including stray light baffles must accommodate all associated thermal and mechanical stresses. In addition, the stray light baffles must be installed in situ on the previously assembled flight modules. The main purpose of the FPAH stray light baffles are to effectively attenuate mission limiting stray light on the FPAs. This paper will provide an overview of the stray light baffle design, mechanical and optical analysis, implementation and test results.

8836-30, Session 7

Optomechanical analysis and testing of a fast-steering secondary mirror prototype for the Giant Magellan Telescope

Andrew C. Corredor, The Univ. of Arizona (United States); Won-Hyun Park, College of Optical Sciences, The Univ. of Arizona (United States); Myung K. Cho, National Optical Astronomy Observatory (United States); Young-Soo Kim, Korea Astronomy and Space Science Institute (Korea, Republic of)

The Giant Magellan Telescope (GMT) will be one of the next class of extremely large segmented mirror telescopes. The GMT will utilize two Gregorian secondary mirrors, and Adaptive Secondary mirror (ASM) and a Fast-steering secondary mirror (FSM). The FSM consists of six off-axis mirrors surrounding a central on-axis circular segment. The segments are 1.1 m in diameter and conjugated 1:1 to the seven 8.4 m segments of the primary. A prototype of the FSM mirror (FSMP) has been developed, analyzed and tested in order to demonstrate the mechanical and optical responses of the mirror assembly when subjected to structural and thermal loadings.

In this paper, the mechanical and thermal performances of the FSMP were evaluated by performing finite element analyses (FEA) in NX Nastran. The deformation of the mirror's lateral flexure was measured when the FSMP was axially loaded and the temperature response of the mirror assembly was measured when exposed to a sample thermal environment. In order to validate the mirror/lateral flexure design concept, the mechanical, optical and thermal measurements obtained from the tests conducted on mirrors having two different lateral flexures were compared to the responses calculated by FEA.

8836-31, Session 7

Development of the fast-steering secondary mirror for the Giant Magellan Telescope

Myung K. Cho, National Optical Astronomy Observatory (United States); Andrew Corredor, The Univ. of Arizona (United States); Won-Hyun Park, College of Optical Sciences, The Univ. of Arizona (United States); Michael Sheehan, Matt Johns, Jonathan Kern, Charlie Hull, Giant Magellan Telescope Project (United States); Eric Hansen, National Solar Observatory (United States); Young-Soo Kim, Korea Astronomy and Space Science Institute (Korea, Republic of); Seongdo Kim, Kyungsung Univ. (Korea, Republic of)

The Giant Magellan Telescope (GMT) Fast-steering secondary mirror (FSM) is one of the GMT two Gregorian secondary mirrors. The FSM is 3.2 m in diameter and built as seven 1.1 m diameter circular segments. The conceiving philosophy used on the design of the FSM segment mirror is to minimize development and fabrication risks ensuring a set of secondary mirrors are available on schedule for telescope commissioning and early operations in a seeing limited mode, thereby mitigating risks associated with fabrication of the Adaptive secondary mirrors (ASM). This approach uses legacy design features from the Magellan Telescope secondary mirrors to reduce risk. The final design of the substrate and support system configuration was optimized using finite element analyses and optical performance analyses. The optical performance predictions of the FSM are based on a substrate with a diameter of 1.058m (on-axis), 1.048m (off-axis), a depth of 120mm, and a face plate thickness of 20mm leading to a mass of approximately 90kg. The optical surface deformations, image qualities, and structure functions for the axial and lateral gravity print-through cases, thermal gradient effects, and dynamic performances were evaluated. The results indicated that the GMT FSM mirror and its support system will favorably meet the optical performance goals for residual surface error and the FSM surface figure accuracy requirement defined by encircled energy in the focal plane. The mirror cell assembly analysis indicated an excellent dynamic stiffness which will support the goal of 20 Hz tip-tilt motion.

8836-32, Session 7

Flexure design development for a fast-steering mirror

Won-Hyun Park, College of Optical Sciences, The Univ. of Arizona (United States); Andrew Corredor, The Univ. of Arizona (United States); Myung K. Cho, National Optical Astronomy Observatory (United States); Young-Soo Kim, Korea Astronomy and Space Science Institute (Korea, Republic of); Ho-Sang Kim, Kyoung-Don Lee, Institute for Advanced Engineering (Korea, Republic of)

Fast-steering mirror (FSM) is a key element in astronomical telescopes to provide real-time angular correction of line-of-sight error due to telescope jitter and wind-induced disturbance. The Giant Magellan Telescope (GMT) will utilize a FSM as secondary mirror under unfavorable wind condition that excites the telescope at the lowest resonance frequency around 8Hz. In FSM, there is a flexure in the center of the mirror that maintains it in place, namely constraining lateral displacements as a lateral support, while still allowing tip-tilt motion to steer. Proper designing of a central flexure is challenging to meet such a flexible specification and lateral loading capability as well as to minimize optical surface distortion forced by redundant constraints at the flexure. We have designed the lateral flexure and estimated its performance from variety of design case studies in a finite element analysis tool. Carefully designed finite element model in sub-system level including the flexure, lightweight mirror and 3 point axial supports allows whether the designed flexure being qualified within specifications. In addition, distorted surface map can be achieved as a function of forces that could be induced in telescope operation or due to mis-alignment errors during assembling. We have also built a test set-up to validate the finite element analysis results. Optical quality was measured by a phase shifting interferometer in various loading conditions and the measurements were decomposed by standard Zernike polynomials to concentrate specific surface shapes and to exclude low order shapes as measurement uncertainties.

Conference 8837: Material Technologies and Applications to Optics, Structures, Components, and Sub-Systems

Monday - Wednesday 26–28 August 2013

Part of Proceedings of SPIE Vol. 8837 Material Technologies and Applications to Optics, Structures, Components, and Sub-Systems

SPIE Optics+Photonics
Optical Engineering + App.

8837-1, Session 1

The market of huge monolithic mirror substrates for optical astronomy

Thorsten Doehring, Univ. of Applied Sciences Aschaffenburg (Germany)

Professional astronomical telescopes are complex optical systems at the limit of technical feasibility. Often monolithic primary mirrors and sometimes even secondary mirrors with huge dimensions are used. Prominent examples are the two reflectors of the Large Binocular Telescope and the giant mirrors of the VLT, GEMINI, and SUBARU. The performance of such precision optical components significantly depends on the physical parameters and the quality of their substrate materials. Within this paper selection criteria for mirror substrates will be discussed, thereby considering the important technical parameters, but also commercial points and aspects of project management. Qualities and limitations of classical mirror substrate materials like Zerodur, ULE, Astrositall, borosilicate glass and Cervit will be discussed and compared to new substrate materials like silicon carbide and beryllium. The different suppliers and their production process will be presented. In addition large mirrors of existing observatories and of telescopes under construction will be listed, thereby concentrating on mirrors above three meter in diameter. An outlook on material trends and on future astronomical telescopes will close this overview on the market of huge monolithic mirror substrates for optical astronomy.

8837-2, Session 1

Large-silicon carbide optics for manufacturability

John W. Pepi, L-3 Communications IOS-SSG (United States)

For space-based use, projected needs are for large optics of the one-meter class that lie under 30 kg/m2 in mass areal density. Current space programs using glass optics, such as Kepler, exhibit a mass of 45 kg/m2, while JWST beryllium optics, including hardware attachment, are as low as 18 kg/m2.

Silicon carbide optics can be made lighter than glass, although not as light as beryllium; however, distinct advantages in thermal conductivity and expansion coefficient are evidenced at all temperatures, allowing for greater thermal flux , minimizing gradients and maximizing performance, both earth and space looking. For manufacturability and production, it is desirable to minimize weight while maintaining reasonable cell spacing for open back lightweight design, which will reduce both cost and risk.

To this end we perform a trade study to build such an optic that meets both mass and stiffness requirements while being within the regime of ease of manufacture. The design study chooses a hexagonal segment, 1.2 meters across flats (1.4 meters corner to corner), mimicking the JWST design. Polishing, mounting, test, and environmental operational errors are duly considered.

8837-33, Session PMon

Laser strength of dielectric interference coatings on optical materials, rods, and non-linear crystals

Vladimir V. Novopashin, Alexsandr V. Shestakov, POLYUS Research and Development Institute (Russian Federation)

The novel technologies and design in lasers and laser elements defined the new demands to optical coatings. The requirements for dielectric interference films include the increasing optical and physical properties. High performance dielectric interference coatings (anti-reflection, dielectric mirrors, polarizers, beam-splitters in broad spectral rage are observed. High resistance to laser radiation is one of the main efficiency parameter. For evaporation materials a traditional electron-beam evaporation method was used. Ion-beam assistance with active O2+ provided to obtain more density films, which are closed to their stoichiometry structure. This is urgent for high power lasers at 1064 nm, lasers in medium infrared region and also for disc lasers. These coatings were deposited on the surface of optical glass BK-7 or quartz, and on the surface of rods, passive Q-switches and nonlinear crystals (LiJO3, LiTaO3, KTP, BBO, LBO, KDP, DKDP). The effect of influence ion-beam at most extent revealed during evaporation oxide materials, where activated the mobility of atoms deposited on substrate. Pre-cleaning by the ion-beam of neutral gas (Ar+) before the evaporation was important when produce mirrors for Y3Al5O12 + Er3+ lasers to reduce the influence of water at 1800 – 3000 nm. Ion source use allowed to conduct the process of surface cleaning water soluble crystals KDP, DKDP, optical materials and crystals that are depended on air environment LBO, BBO, LiJO3. The improvement of optical properties evaporated films led to obtaining almost perfectly coatings and stabilized operating characteristics of lasers and laser elements.

8837-34, Session PMon

Measurements of density by using the emission-intensity ratio between ionic to atomic lines in a Nd:YAG LIBS indicate aluminum alloy (zeolites) fantastic properties

Osama M. Khalil, Cairo Univ. (Egypt)

Optical emission in LIPS is found to be an efficient method for determining material hardness by estimate the ratio between ionic lines and atomic lines for elements exist in the samples under test. We conclude in our work that the ratio between ionic lines and atomic lines gives indication about density not Hardness. The results indicate that aluminum alloy samplesunder compression have a higher hardness and low density. The comparison between the practical and the theoretical resultsindicate the effect of crater development and rim formation on thermal and mechanical couplingwhich affected the ablation rate of the laser beam.

8837-35, Session PMon

Vacuum-packaged infrared MEMS image sensor array

Jae Hong Park, National Nanofab Ctr. (Korea, Republic of)

Vacuum continues to be an enabling environment for electronic devices into the 21st century. Here, examples include infrared IR sensing systems. Outgassing from surfaces in these systems destroys these controlled ambients over time days to years. MEMS and MOEMS are not immune to these issues. Most of MEMS based sensors are sensitive to the operating pressure, the partial pressure of water vapor in the package, or both. For example, infrared sensors need to operate in a pressure 10-3 Torr in order to be thermally isolated from the outside world and maintain adequate sensitivity. The situation is further complicated by the need for high degrees of hermeticity leak rates on the order of 10-12 atm-cc/s and the lack of space to mount getters to control the contaminants in the package. Hermeticity is currently a significant issue in the microelectronics packaging field as a whole.

Hermetically packaging MEMS devices in a reliable and economical manner is a topic of great interest to the MEMS community. The development of MEMS technology has reached a point where the packaging of the device is proving to be more difficult than the actual device development itself. Many development groups are finding their efforts stymied at this point, and interest in MEMS packaging and related topics is at a high level. In this study, among various and significant factors such as structural and geometric design of a device, considering optical design, thermal design, electrical design, mechanical design, and process design, fabrication of the device, design and fabrication of a circuit, device analysis, property measurement, design and fabrication of optical system, and design and fabrication of package module on R&D for MEMS based opto-electro-thermo-mechanical device, we will address a methodology for design, fabrication, and analysis of MEMS based infrared sensor array packaging. Also, ultimate type of wafer level packaging will be introduced in a view point of design factors and structural differences compared with on-going metal packaging

8837-3, Session 2

Aluminum alloy 6061 and RSA-6061 heat treatment for large-mirror applications

Trent Newswander, Blake G. Crowther, Utah State Univ. Research Foundation (United States); Guido Gubbels, Roger Senden, RSP Technology (Netherlands)

Aluminum mirrors and telescopes can be built to perform well at a relatively low cost and short schedule if the material is processed correctly. However, the difficulty of making high quality aluminum telescopes increases as the size increases, starting with uniform heat treatment through the thickness of large mirror substrates. In this study, large aluminum blanks of both conventional 6061 per AMS-A-22771 and RSA-6061 were built, heat treated and stress relieved. Both blanks were destructively tested with a cut through the thickness. Hardness measurements and tensile tests were completed. The convential 6061 results showed good hardness throughout the part and good hardness uniformity. RSA-6061 hardness was less uniform and did not meet T6 specification in the center. Further testing of the RSA-6061 discovered important process modifications for successful T6 heat treating of the material. We present our results in this paper and make suggestions for modification of procedures and future work.

8837-4, Session 2

Design and manufacturing considerations for 0.25-1.5 meter beryllium telescopes for current and future space missions

Michael N. Sweeney, Mark R. Warren, Joseph Ho, Tom Vettese, Jeff Ruzan, Jeff Calvert, Don Douthit, General Dynamics-Global Imaging Technologies (United States)

Recently there has been resurging interest in beryllium telescopes ranging from 0.25-1.5 meter in aperture for various NASA space missions. The central design feature for each mission currently under consideration is an axially symmetric, all beryllium telescope.

Design considerations include achieving minimized mass simultaneous with demanding structural, thermal, and optical requirements on orbit after sustaining the rigors of space launch. Modern analysis tools and modeling techniques enable simulation of telescope wavefront errors resulting from environmental effects and the influences of bi-metallic bending. Manufacturing considerations include diamond point turning, coordinate measurement machine profilometry, computerized grinding and polishing, brazing of complex beryllium structures, very thin electroless nickel plating, and other advanced manufacturing technologies imperative to successful visible–NIR optical performance. Current design and manufacturing efforts on 0.60, 0.80, and 1.0 meter beryllium telescopes are profiled to illuminate the confluence of applicable design and manufacturing technologies.

8837-5, Session 2

Cost-effective aluminum beryllium mirrors for critical optical applications

Jack Duich, David Feikema, Inrad Optics (United States); Chris Huskamp, IBC Engineered Materials Corp. (United States); Raymond White, IBC Advanced Alloys (United States)

The unique performance of aluminum-beryllium frequently makes it an ideal material for manufacturing precision optical-grade metal mirrors. Traditional methods of manufacture utilize hot-pressed powder block in billet form which is subsequently machined to final dimensions. Complex component geometries such as lightweighted, non-plano mirrors require extensive tool path programming, fixturing, and CNC machining time and result in a high buy-to-fly ratio (the ratio of the mass of raw material purchased to the mass of the finished part.) This increases the cost of the mirror structure as a significant percentage of the procurement cost is consumed in the form of machining, tooling, and scrap material that do not add value to the final part. Inrad Optics, Inc. and IBC Advanced Alloys Corp. undertook a joint study to evaluate the suitability of investment-cast Beralcast(R) 191 and 363 aluminum-beryllium as a precision mirror substrate material. Net shape investment castings of the desired geometry minimizes machining to just cleanup stock, thereby reducing the recurring procurement cost while still maintaining performance. The thermal stability of two mirrors, (one each of Beralcast(R) 191 and Beralcast(R) 363), was characterized from -40F to +150F. A representative pocketed mirror was developed, including the creation of a relevant geometry and production of a cast component to validate the approach. Information from the demonstration unit was used as a basis for a comparative cost study of the representative mirror produced in Beralcast(R) and one machined from a billet of AlBeMet(R) 162 (AlBeMet(R) is a registered trademark of Materion Corporation). The technical and financial results of these studies will be discussed in detail.

8837-6, Session 2

The isotropic behavior of an anisotropic material: single crystal silicon (SCSi)

Douglas R. McCarter, McCarter Machine, Inc. (United States)

Single crystal silicon (SCSi), with its diamond cubic crystal structure, is completely isotropic in most properties important for stable optics. For example, thermal and optical properties are completely isotropic. The elastic and mechanical properties however are direction dependent. But we show that in spite of this, near-isotropic behavior can be achieved with component designs that utilize the maximum elastic modulus in directions with the highest loads.

The most significant anisotropic property of SCSi is the Young's modulus of elasticity. Literature values vary substantially around a value of 145 GPa. The truth is that the maximum value is 169 GPa in the <110> crystallographic direction, higher than that of many materials such as aluminum and invar. And since Poisson's ratio in this direction is an extremely low 0.064, distortion in the plane normal to the load is insignificant. While the minimum modulus is 130 GPa, a calculated average value, such as the Reuss average used for polycrystalline Si, is close to the maximum at approximately 160 GPa. So that he minimum modulus is almost irrelevant.

It is clear then that near-isotropic elastic behavior can be achieved in SCSi components in spite of anisotropic elastic properties when designs utilize this unique behavior. In this paper we will demonstrate sub-micron and sub-second response to loads placing SCSi as Pre-eminent in isotropic stability.

8837-7, Session 2

Design and manufacturing considerations for high-performance gimbals used for land, sea, air, and space

Michael N. Sweeney, Bryan L. Redd, Tom Vettese, David Uchida, General Dynamics-Global Imaging Technologies (United States)

High performance stabilized EO/IR surveillance and targeting systems are in demand for a wide variety of military, law enforcement, and commercial assets for land, sea, air, and space. Operating ranges, wavelengths, and angular resolution capabilities define the requirements for EO/IR optics and sensors, and line of sight stabilization. Many materials and design configurations are available for EO/IR pointing gimbals depending on trade-offs of size, weight, power, performance, and cost. Space and high performance military aircraft applications are often driven toward expensive but exceptionally performing beryllium and aluminum beryllium components. Commercial applications often rely on aluminum and composite materials.

Gimbal design considerations include achieving minimized mass and inertia simultaneous with demanding structural, thermal, optical, and scene stabilization requirements when operating in dynamic operational environments. Manufacturing considerations include precision lapping and honing of ball bearing interfaces, brazing, welding, and casting of complex aluminum and beryllium alloy structures, and molding of composite structures. Several notional and previously developed EO/IR gimbal platforms are profiled that exemplify applicable design and manufacturing technologies.

8837-8, Session 3

Optical test results of carbon composite mirrors from MISSE 7

Robert C. Romeo, Robert N. Martin, Composite Mirror Applications, Inc. (United States)

We report on the optical performance of carbon fiber reinforced polymer composite (CFRP) mirrors after 1 year exposure onboard the Materials International Space Station Experiment (MISSE 7). Mirror samples were placed on the MISSE 7 tray, outside the ISS from October 2009 and retrieved September 2011. The results from testing the returned flight samples show degradation in the mirror's aluminum coating. However, the surface figure of each mirror remained largely unchanged after 1 year duration on orbit. Test results will be compared against the original, pre-flight mirror tests for each of the 3 samples.

8837-10, Session 3

Thermal testing of a stacked core mirror for UV applications

Gary W. Matthews, Exelis Visual Information Solutions (United States); Charles S. Kirk, Steven P. Maffett, ITT Exelis (United States); H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States); Calvin E. Abplanalp, Jet Propulsion Lab. (United States); Ron Eng, William R. Arnold Sr., NASA Marshall Space Flight Ctr. (United States)

The ASTRO2010 Decadal Survey stated that an advanced large-aperture ultraviolet, optical, near-infrared (UVOIR) telescope is required to enable the next generation of compelling astrophysics and exoplanet science; and, that present technology is not mature enough to affordably build and launch any potential UVOIR mission concept. Under Science and Technology funding, NASA's Marshall Space Flight Center and ITT Exelis have developed a more cost effective process to make 4m monolithic spaceflight UV quality, low areal density, thermally and dynamically stable primary mirrors. A proof of concept mirror was built and tested down to 250K which would allow imaging out to 2.5 microns. This mirror was thermally tested at the Marshall Spaceflight Center to understand the thermal changes between the processing temperature of 293K and the potential low end of the operational temperature of 250K. Isothermal testing results and front plate gradient results have been evaluated and compared to analysis predictions. Measurement of gravity effects on surface figure will be compared to analytical predictions. Future testing of a larger Pathfinder mirror will also be discussed.

8837-11, Session 3

Cryogenic optical performance of a lightweighted mirror assembly for future space astronomical telescopes: optical test results and thermal optical model *(Invited Paper)*

Ron Eng, William R. Arnold Sr., Markus A. Baker, NASA Marshall Space Flight Ctr. (United States); Ryan M. Bevan, NASA Marshall Space Flight Ctr. (United States) and The Univ. of Alabama in Huntsville (United States); James R. Carpenter, Michael R. Effinger, Darrell E. Gaddy, Brian K. Goode, Jeffrey R. Kegley, William D. Hogue, Richard D. Siler, W. Scott Smith, H. Philip Stahl, John M. Tucker, Ernest R. Wright, NASA Marshall Space Flight Ctr. (United States); Gregory L. Burdick, Craig D. Hanson, Charles S. Kirk, Steven P. Maffett, Gary W. Matthews, ITT Exelis (United States)

A 40 cm diameter mirror assembly was interferometrically tested at room temperature down to 250 degrees Kelvin for thermal deformation. The 2.5 m radius of curvature spherical mirror assembly was constructed by low temperature fusing three abrasive waterjet core sections between two face sheets. The 93% lightweighted Corning ULE mirror assembly represents the current state of the art for future UV, optical, near IR space telescopes. During the multiple thermal test cycles, test results of interferometric test, thermal IR images of the front face were recorded in order to validate thermal optical model.

8837-12, Panel Discussion

ESA initiatives to improve mechanical design and verification methods for ceramic structures *(Invited Paper)*

Graham Coe, European Space Research and Technology Ctr. (Netherlands)

Influence of low-Earth orbit exposure on the mechanical properties of silicon carbide

David B. Witkin, The Aerospace Corp. (United States)

The influence of the Low-Earth orbit (LEO) environment on the mechanical strength of silicon carbide (SiC) was evaluated on two flight experiments as part of the Materials on the International Space Station Experiment (MISSE). SiC samples for modulus of rupture (MOR) and equibiaxial flexural strength (EFS) testing were flown on the Optical and Reflector Materials experiments (ORMatE) as part of MISSE-6 (launched on STS-123, March 2008; returned on STS-128, September 2009) and MISSE-7 (launched on STS-129, November 2009; returned on STS-134, June 2011). Two different SiC vendors provided material for each flight experiment. The goal of the experiments was to measure mechanical

properties of the flight samples and compare them to an equal number of similar samples in control and traveler sample sets. Complete characterization of the strength of brittle materials typically requires many more test specimens than could be reasonably accommodated on the ORMatE sample tray and statistical models based on few samples include large uncertainties. Understanding the results of the mechanical tests of MISSE samples required comparison to results from a statistically valid number of samples. Prior testing by The Aerospace Corporation of material supplied by the same four vendors was used to evaluate the MISSE results, including flight and control samples. The results showed that exposure to LEO over the durations covered by MISSE 6 and 7 (approximately 18 and 20 months, respectively) did not alter the mechanical strength of the silicon carbide for any of the vendors' materials.

8837-14, Session 4

Comparison of SiC mirror approaches

Keith Carrigan, Michael Riso, Shayna Khatri, Christopher Douglas, L-3 Communications IOS-SSG (United States)

Silicon Carbide (SiC) mirrors hold many advantages over traditional optical materials and are increasingly common in optical systems. The wide range of optical applications necessitates different approaches to the manufacturing and finishing of SiC mirrors. Three key advancements have led to this differentiation: 1) manufacturing of CVD clad SiC mirrors in near cost and schedule parity with Zerodur, 2) super-polish of amorphous Silicon claddings, 3) low-roughness polishing results of bare reaction-bonded SiC aspheres. Three approaches which utilize these advancements will be discussed, each with its own strengths and weaknesses for specific applications. The relative schedules and performance of these approaches will also be compared, with Zerodur used as a reference.

8837-15, Session 4

HoneySiC: a new optomechanical material for low-areal cost and density

William A. Goodman, Trex Enterprises Corp. (United States)

One of the major problems perceived for silicon carbide mirrors and structures is the cost associated with machining and lightweighting the material to the specifications of a drawing. Molded pedigrees of silicon carbide address these concerns by casting or molding a slurry and prefiring the slurry to make a consolidated and porous greenbody which is relatively soft and not very difficult to machine. The machined greenbody is then infiltrated with molten silicon in an exothermic process that yields a two phase reaction bonded silicon carbide material that must undergo a final machining step. Converted silicon carbide pedigrees machine a graphite or carbon/carbon precursor material to near net shape and then infiltrate the part with gaseous silicon monoxide or molten silicon to convert most or all of the carbon to silicon carbide. Some pedigrees are highly porous, while others may be dense of containing 2 or 3 different phases of material. We have created and demonstrated a new fiber reinforced silicon carbide material that combines the benefits of molding, infiltration and conversion processes. The resulting HoneySiC material requires a minimal amount of machining. HoneySiC material achieves lightweighting of 92% relative to bulk material and net production cost on the order of $38K per square meter (unpolished), less than half of NASA's goal of $100K per square meter.

8837-16, Session 4

State-of-the-art silicon carbide optical telescope assembly for the JMAPS mission

Daniel J. Catropa, L-3 Communications IOS SSG (United States)

L-3 Communications IOS-SSG (L-3 SSG) has recently completed development of an ultra low wavefront error and highly stable Silicon Carbide (SiC) optical payload for the Joint Milli-Arcsecond Pathfinder Survey (JMAPS) mission. Selection of SiC as the opto-mechanical material was driven by the JMAPS requirements for extremely low residual optical aberrations and distortion, and state-of-the-art temporal and thermal stability. JMAPS utilizes a passively athermalized design, combining SiC optics with aggressively lightweighted SiC metering structures. The resulting hardware has been optically tested over temperature, demonstrating an exceptionally low and stable system level wavefront error. This exceptional performance, combined with the aggressively lightweighted sinterbonded SiC structures developed, result in an instrument which represents the state-of-the-art from the perspective of optical performance and structural efficiency. We will provide an overview of the system, with emphasis on the SiC opto-mechanics, and system level test results.

Keywords: Silicon Carbide, JMAPS, Optical Testing, Space Sensors

8837-17, Session 4

Novel reactive chemical mechanical polishing technology for fabrication of SiC mirrors

Rajiv K. Singh, Arul C. Arjunan, Kannan Balasundaram, Purushottam Kumar, Sinmat, Inc. (United States)

Silicon carbide (SiC) is considered an excellent material for high performance optical applications because of its superior properties including extremely high specific stiffness (E/?), high thermal conductivity and excellent dimensional stability. However, silicon carbide is next only to diamond in hardness and is chemically inert. Both the precision machining required for shaping and the conventional finishing processes (lapping, polishing) of SiC mirrors is extremely slow making it expensive to produce a light weighted, super-polished SiC substrate. In addition, diamond which is typically employed to achieve reasonable polishing rate, creates sub-surface damage, high density of scratches and other polishing defects which leads to mid and high spatial frequency errors. This talk will focus on a novel reactive chemical mechanical polishing process for SiC mirrors which increases the removal rate by several folds over conventional process at the same time reduce the rms roughness to <0.5 nm. Challenges associated with polishing of polycrystalline SiC and multiple phase material e.g. grain delineation will be discussed. The effect of various components, chemical and mechanical, of the reactive polishing slurry on surface roughness will be discussed.

8837-18, Session 4

Manufacturing and optical testing of 800-mm lightweight all C/SiC optics

Masataka Naitoh, Tadashi Imai, Haruyoshi Katayama, Masahiro Suganuma, Yoshio Tange, Ryota Sato, Japan Aerospace Exploration Agency (Japan); Hidehiro Kaneda, Takuma Kokusho, Nagoya Univ. (Japan); Keigo Enya, Takao Nakagawa, Masaki Kotani, Kenta Maruyama, Japan Aerospace Exploration Agency (Japan)

We manufactured an 800mm diameter lightweight telescope that consists wholly of carbon-fiber reinforced silicon carbide (C/SiC) that is called HB-Cesic. All its parts, including optical bench and support structures, were made out of HB-Cesic. Owing to its high specific stiffness and high thermal stability, silicon carbide is becoming one of the outstanding materials applied especially to large, space-borne optics. Technologies of highly accurate optical measurement of such large telescopes on vacuum or cryogenic circumstances are also indispensable.

We tested the cryogenic deformation of the primary mirror mounted on an optical bench in a liquid-helium chamber. During the test, both the mirror and the optical bench were cooled to 18K. The deformation was 110nm RMS with no significant residual deformation after cooling, which

is very promising for the applicability of the C/SiC composite to large light weight cryogenic space optics.

In addition, we assembled the primary mirror into the 800mm telescope with a high order convex secondary mirror and tested its optical performances at the 6m diameter radiometer space chamber at Tsukuba Space Center in JAXA, where we prepared the interferometric metrological facilities to establish techniques to test large optical systems in a horizontal light-axis configuration.

We carried out the optical measurements of the 800mm telescope by stitching interferometry with sub-aperture array consisting of 300mm autocollimating flat mirror. We verified that our algorithm and simulations of the stitching method is to be applied to 3m-class aperture telescopes such as SPICA with an 1m-class optical flat as a sub-aperture.

8837-19, Session 4

Effect of grain size on microstructure, properties, and surface roughness of reaction bonded SiC ceramics

Michael Aghajanian, Craig Emmons, M Cubed Technologies, Inc. (United States); Steve P. Rummel, Paul Barber, II-VI Inc. (United States); Christopher T. Robb, Douglas L. Hibbard, Exotic Electro-Optics, Inc. (United States)

Silicon carbide (SiC) based ceramics have received significant study for optical applications due to high specific stiffness, high thermal conductivity and low coefficient of thermal expansion (CTE). Reaction bonded SiC ceramics, which are composites of SiC and Si, are of particular interest due to large size and complex shape capability. The behavior of these ceramics is very much affected by the respective volume fractions of SiC and Si, and the grain size of the SiC phase. The present work examines Si contents ranging from 10 to 35 vol. %, and SiC grain sizes ranging from 6 to 50 microns, with the goal of optimizing properties and finishing capability for optical uses. Microstructures are reviewed; physical, mechanical and thermal properties are presented; and post-polishing surface roughness data are provided.

8837-20, Session 5

Cryogenic silicon carbide mirrors for infrared astronomical telescopes: lessons learned from AKARI for SPICA *(Invited Paper)*

Takashi Onaka, The Univ. of Tokyo (Japan); Hidehiro Kaneda, Nagoya Univ. (Japan); Mitsunobu Kawada, Keigo Enya, Takao Nakagawa, Institute of Space and Astronautical Science (Japan)

Silicon carbide (SiC) has good thermal conductivity, high stiffness, and a relatively low specific density, all of which are advantageous to the application to telescopes operating at cryogenic temperatures. The first Japanese astronomical infrared space mission AKARI, which was launched in 2006 February and completed the second generation all-sky survey at 6 bands from mid- to far-infrared, employed a 700mm cryogenic telescope made of specially developed SiC. It was a sandwich-type of SiC composed of a lightweight porous core and a dense chemical vapor deposition (CVD) coat to decrease the specific density and facilitate machining without losing polishability to achieve the required wave-front errors. Optical tests at cryogenic temperatures (~10K) of 160-mm sample mirrors have demonstrated that the AKARI mirror SiC has a high stability at cryogenic temperatures, while the mirror support of the compact design became the primary source of wave-front errors of the telescope system. Taking the advantage of heritage of the AKARI telescope development as well as ESA's Herschel telescope, we are planning the next infrared space mission, SPICA (Space Infrared Telescope for Cosmology and Astrophysics) of a 3.2m cooled telescope in participation of ESA using SiC or carbon-fiber-reinforced SiC materials. In this presentation, we summarize the development of AKARI SiC telescope and present the development activities of the SPICA telescope from the point of view of SiC being as the material for cryogenic space telescopes.

8837-21, Session 5

Design and fabrication of ultralight and stable Cesic(R) mirrors

Matthias Krödel, ECM Engineered Ceramic Materials GmbH (Germany)

In the frame of a German R & D program ECM designed and fabricated an ultra stabile light weighted mirror to demonstrate the capability of Cesic® to manufacturing of such mirror structures especially for future large scale mirrors and structures. In this paper I will describe the design approach from a traditional open back mirror to the complex shaped super light weighted closed back mirrors in order to see the advantages of such mirrors compared to traditional mirrors.

Also I will report about the manufacturing of such complex shaped closed back mirrors which we developed during this R & D program.

8837-22, Session 5

Fabrication of SiC aspheric mirrors with low mid-spatial error

Flemming Tinker, Kai Xin, Aperture Optical Sciences Inc. (United States)

Manufacturing optics for today's most precise reflective imaging systems requires polishing techniques which enable extreme control over surface gradients and periodic features. This is critical for x-ray optics, which, are used at grazing incidence, high damage threshold laser optics, as well as applications in remote sensing, lithography and many other precision imaging applications. Most modern manufacturing techniques of fast aspheric optics produce mid and high spatial frequency features during grinding and polishing, which ultimately limit image quality. Mitigation of such features can be difficult, costly, and time consuming. Corrective finishing of such extreme optics must address and mitigate the impact of surface features corresponding to these various spatial scale lengths. This presents unique challenges to deterministic finishing techniques, which employ stable work functions and tool paths to surgically correct for surface errors. While such technologies and techniques may correct for errors in one spatial frequency region, they may inadvertently create new periodic errors, which can further degrade image performance. Manufacturing design must therefore address correction of the full measurable power spectrum to optimize image performance. This paper will discuss how controlled force grinding, robotic polishing, and surface smoothing can be employed to minimize and mitigate mid-spatial errors in fast silicon carbide aspheric mirrors. Recent experience and results are presented, which demonstrate how fabrication techniques that produce minimal surface gradients in the mid-spatial frequency region can produce superior image quality as predicted by the encircled energy or the point spread functions.

8837-23, Session 5

Correlation of mid-spatial features to image performance in aspheric mirrors

Flemming Tinker, Kai Xin, Aperture Optical Sciences Inc. (United States)

Modern techniques in deterministic finishing approaches employ geometrically small tools and removal functions for precision correction of fast aspheres. There are fundamentally sound and often necessary reasons for small tool finishing, however, a consequence is the creation of a residual trail of periodic surface "ripples" or textures in the surface

that can have profound impact on system imaging performance. There are many reasons for the creation of periodic features however, first order effects often result from the polishing tool or contact spot geometries. Creation of such features are inescapable. Therefore, it becomes necessary to better characterize them, understand their impact, and develop preventive, compensating and mitigating strategies of controlling their amplitudes and frequencies. Traditional specifications like Peak to Valley and RMS wavefront specifications cannot fully predict image quality in fast aspheric optics unless they are specified over precise spatial scale lengths (or frequencies). In this paper we will explore a variety of fast aspheric mirrors produced by Aperture Optical Sciences Inc. in the past year and will attempt to correlate mid-spatial frequency errors with typical metrics of predictive image quality such as the encircled energy function and the point spread function.

8837-24, Session 5

A sound basis for Snap-Together

Hugo Vargas, Poco Graphite, Inc. (United States); Flemming Tinker, Aperture Optical Sciences Inc. (United States)

The opto-mechanical performance advantages of silicon carbide (SiC) material are well understood and sought after for space and airborne applications. Furthermore, manufacturing technology maturity for making substrates and mirrors has evolved considerably over the past 10 years. What has been less known over this same period were the effects on improving and optimizing the fabrication process of a complete SiC assembly, that is, assembling and aligning mounting structures and mirrors. The performance of an athermal system is the 'holy grail' of design desires but if the challenges to achieving the optical assembly overwhelm the concept over traditional configurations (e.g., glass adhered to metal mounting structures), then a true technology advancement has not been attained. Entegris has manufactured several SiC optics and structures demonstrators under SBIR and BAA efforts, and now commercial deliverables, and has validated manufacturing pathways that clearly demonstrate advantages at many levels. This paper examines the details of fabricating a silicon carbide telescope leading to the assembly and alignment phase and the benefits within those phases directly attributed to Entegris' SUPERSiC material and manufacturing technology.

In 2012, Poco Graphite and Aperture Optical Sciences delivered a 6 inch on-axis two-mirror telescope demonstrator to the Air Force Research Laboratory as part of Poco's Broad Agency Announcement contract. The unique characteristics of the results attained after initial assembly will be discussed in this paper. Of particular interest are ease of assembly, first-light reading, and repeatability of the silicon carbide telescope. After precision machining and polishing of the individual silicon carbide structures and mirrors, optical metrology performed yielded a "first-light" reading slightly over 2 waves Peak-to-Valley. To understand repeatability characteristics, disassembled and re-assembled was performed multiple times and was timed 30 minutes total per cycle. The more impressive characteristic was that interferometer readings after each cycle yielded a maximum 0.2 waves Peak-to-Valley difference across the combined readings. This is a clear indication of the benefits of a highly stable material coupled with a superior manufacturing technology.

8837-25, Session 6

Development of CFRP mirrors for space telescopes

Shin Utsunomiya, Tomohiro Kamiya, Ryuzo Shimizu, Japan Aerospace Exploration Agency (Japan)

CFRP (Caron fiber reinforced plastics) have superior properties of high specific elasticity and low thermal expansion for satellite telescope structures. However, difficulties to achieve required surface accuracy and to ensure its stability in orbit have discouraged CFRP application as mirrors. We developed ultra-light weight and high-precision CFRP mirrors composed of CFRP skins and CFRP core sandwich structure using a replica technique.?The shape accuracy of demonstrated mirrors of 150 mm in diameter was 0.8 ?m RMS and the surface roughness was 5 nm RMS as fabricated. This improvement was achieved through observation of surface profiles at each phases of fabrication process of CFRP mirrors by using a surface profiler of scanning white-light interferometry. Technique to observe surface profiles as a function of observed dimension and measuring interval makes it possible to discern various causes of surface bumpy patterns. Optimization of process conditions improved surface accuracy of bare CFRP face skins to less than 1?m RMS. After sandwiched then replicated, surface accuracy of flat sandwich panels of 150 mm square was improved to 0.2 ?m RMS with surface roughness of 6 nm RMS. The surface accuracy vs. size of trial models indicated good possibility of fabrication of over 1m size mirrors of surface accuracy of 1?m. Stability of surface accuracy of CFRP mirrors against temperature and moisture will be presented elsewhere.

8837-26, Session 6

Composite tube manufacturing repeatability and performance as determined by precision measurements of thermal strain

Anthony M. Bluth, ATK Aerospace Structures (United States); Lenn A. Riddle, ATK Space Structures and Components (United States); James R. Tucker, ATK Space Systems (United States)

Composite materials often carry the reputation of demonstrating high variability in critical material properties. The JWST telescope metering structure is fabricated of several thousand separate composite piece parts. The stringent dimensional stability requirements on the metering structure require the CTE of every composite piece be verified either at the billet or piece part level. JWST is unique in that it has required the manufacturing of several hundred composite billets that cover many lots of prepreg and many years of fabrication. The thermal strain pass/fail criteria include limitations on thermal strain variation around a prescribed nominal when measured from 293 K down to 20 K and on the local thermal expansion rate between 30 K and 50 K. A precision measurement facility was developed that could measure at the required accuracy and at a pace that supported the composite part fabrication rate. The test method and facility is discussed and the results of a statistical process analysis of the flight composite billets are surveyed.

8837-27, Session 6

Prediction and measurement of composite tube twist and bending due to thermal loading

Anthony M. Bluth, ATK Aerospace Structures (United States); James R. Tucker, ATK Space Systems (United States); Lenn A. Riddle, ATK Space Structures and Components (United States)

Composite materials are applied in precision optical metering structures because of their low thermal expansion properties in concert high specific stiffness. Twisting and bending of long composite tubes, such as the secondary mirror support structure for the JWST telescope, requires control and verification. A stochastic modeling method was applied that simulates the manufacturing process variability and estimates ranges for expected twist and bend over the tube length from ambient to cryogenic temperatures. A development strut for the JWST secondary mirror support structure was fabricated and a metrology system was designed and implemented that measured the bend and twist response from ambient to 20 K. Modeling methods and predictions are outlined. The test metrology and results are summarized, along with a comparison between test and prediction.

8837-28, Session 7

Development of transparent polycrystalline beta-silicon carbide

Shyam S. Bayya, Guillermo R. Villalobos, Jasbinder S. Sanghera, U.S. Naval Research Lab. (United States); Michael P. Hunt, Univ. Research Foundation (United States); Bryan M. Sadowski, Ish D. Aggarwal, Sotera Defense Solutions, Inc. (United States); Michael K. Cinibulk, Air Force Research Lab. (United States); Carmen M. Carney, Kristin A. Keller, UES, Inc. (United States)

Transparent beta-SiC is of great interest because its high strength, low coefficient of thermal expansion, very high thermal conductivity, and cubic crystal structure give it a very high thermal shock resistance. A transparent, polycrystalline beta-SiC window will find applications in armor, hypersonic missiles, and thermal control for thin disc lasers. SiC is currently available as either small transparent vapor grown disks or larger opaque shapes. Neither of which are useful in window applications. We are developing sintering technology to enable transparent SiC ceramics. This involves developing procedures to make high purity powders and studying their densification behavior. We have been successful in demonstrating transparency in thin sections using Field Assisted Sintering Technology (FAST). This paper will discuss the reaction mechanisms in the formation of beta-SiC powder and its sintering behavior in producing transparent ceramics.

8837-29, Session 7

Novel high-performance polishing process for fabrication of sapphire window

Rajiv Singh, Kannan Balasundaram, Arul C. Arjunan, Purushottam Kumar, Sinmat, Inc. (United States)

Sapphire is highly transparent in the wavelength range 170 nm (UV) and 5.3 µm (IR) which makes it uniquely suitable for sensor window materials in electro-optical systems. Presently one of the outstanding challenges is the affordable, production of low-roughness, low-stress, large-area sapphire windows. Since, sapphire is among the hardest materials next only to few ultra-hard materials e.g. diamond, silicon carbide and also chemically inert, the polishing of sapphire is a challenge. The use of aggressive grinding technique provides relatively high removal rate of sapphire, however it leaves high degree of roughness, scratches and sub-surface damage which extends 2 to 5 microns below the surface. The final step of chemical mechanical polishing which uses slurries based on softer particles such as colloidal silica is a very slow process, and represents a major bottleneck. This talk will focus on a novel rapid chemical mechanical polishing process to increase the material removal rate during polishing of sapphire by greater than 2 fold over conventional process. A comparison will be made with the current state of the art process with respect to material removal rate, surface quality and window flatness. Polishing mechanism of sapphire and its correlation with process parameters e.g. particle, pad, pressure etc. will be discussed.

8837-30, Session 7

Silicate and direct bonding of low-thermal expansion materials

Gerhard Kalkowski, Simone Fabian, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany); Carolin Rothhardt, Friedrich Schiller Univ. (Germany); Mathias Rohde, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany); Paul Zeller, EADS Astrium GmbH (Germany); Stefan Risse, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany)

We investigate materials adapted joining technologies for silicate glasses in high precision opto- mechanical applications using 150 mm diameter samples of ultra-low thermal expansion glass. Plane-spherical elements of exactly opposite radii and thicknesses of about 5 mm (massive) and 15 mm (perforated with bore holes), respectively, were first bonded at their spherical interfaces by a water based sodium silicate solution. Subsequently, the plane backside of the perforated part was closed with a glass wafer of 1.5 mm thickness by hydrophilic direct bonding to obtain a stiff, light-weight compound. Reliable bonds were achieved after extensive chemical cleaning and activation of the surfaces similar to previous practice /1/.

The dimensional stability of bonded compounds was tested in a vacuum chamber by monitoring flatness changes during thermal cycling. Gold coated plane surfaces of both sides were inspected at a resolution of 16 nm with a Fizeau type interferometer at temperatures between 330 K and 80 K. Probe mounting is displayed in Fig.2. Our contribution describes the bonding processes and documents the flatness changes of only about 30 nm RMS between both thermal extremes, illustrating the great potential of these technologies for application in space.

This work was supported by BMWI/DLR (Germany) under contract No. 50YB0814.

8837-31, Session 7

Recent developments in transparent spinel ceramic and composite windows

Shyam S. Bayya, Guillermo R. Villalobos, Woohong R. Kim, Jasbinder S. Sanghera, U.S. Naval Research Lab. (United States); Geoffrey D. Chin, Michael P. Hunt, Univ. Research Foundation (United States); Bryan M. Sadowski, Fritz Miklos, Ish D. Aggarwal, Sotera Defense Solutions, Inc. (United States)

The Naval Research Laboratory has pioneered the development of sintering processes for making highly transparent optical ceramics. For example, we have demonstrated the fabrication of record low absorption loss spinel as an exit window for High Energy Laser systems and rare earth doped Y2O3 and Lu2O3 for solid-state ceramic lasers. We have also developed thick spinel windows for submarine photonic masts and predicted the performance of an imaging system using testing and modeling. More recently, we have developed a novel approach of hot pressing where a transparent ceramic is produced in the net shape without requiring post polishing. This technology will result in significant cost savings associated with polishing the final optical element.

We had earlier identified a Barium GalloGermanate (BGG) glass with matching index and expansion coefficient to spinel. We had demonstrated fabrication of a laminated dome for the Joint Air to Ground Missile (JAGM) program and the technology was transitioned to industry. We have pushed this technology further by developing a BGG glass – spinel ceramic transparent micro-composite which can be processed well below sintering temperatures. To address the poor strength of BGG glass compared with spinel, we developed an ion-exchange process and achieved strengths up to 450 MPa. The results and status of all these development efforts will be discussed at the meeting.

8837-32, Session 7

Investigation of negative index in dispersive, chiral materials via contra-propagating velocities under second-order dispersion (GVD)

Monish R. Chatterjee, Tarig A. Algadey, Univ. of Dayton (United States)

Negative refractive index arises typically in metamaterials via multiple routes. One such avenue is the condition where the Poynting vector of the electromagnetic wave is in opposition to the group velocity in the material. An early work along this route in a chiral material led to the well-known result of requiring very large (non-realizable) chirality. Thereafter, a combination of chirality together with first-order dispersion was examined using plane wave electromagnetic analysis. To arrive at the conclusions in that approach, the three wave velocities (energy, group and phase) were derived under first-order dispersion in permittivity, permeability and chirality. Negative index in this approach was established under the condition of contra-propagating group and phase velocities. Regions of negative index were found analytically by assuming standard dispersive models (such as Condon). In this paper, we re-visit the negative index problem under higher-order dispersion. Accordingly, we re-examine the plane wave propagation model under parametric dispersion where each material parameter (ε, u, K) is dispersively expanded up to the second order in frequency. Such a physical effect may be traced to group velocity dispersion (GVD) in the material. Field solutions are then obtained under the GVD effect, and extended to the evaluation of the energy, phase and group velocities. Some well-known GVD models from the electromagnetic literature are then applied to the derived results for ve, vg and vp with dispersive coefficients, and conditions are established for the emergence of negative index. We further discuss the realizability of negative indices in practical GVD terms.

8838-1, Session 1

Angle and wavelength resolved light scattering

measurement of optical surfaces and thin films

Sven Schröder, David Unglaub, Alexander von Finck, Marcus Trost, Matthias Hauptvogel, Tobias Herffurth, Matthias Opel, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany); John C. Stover, The Scatter Works Inc. (United States); Angela Duparré, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany)

Light scattering metrology has become more and more important with the development of cutting-edge optical components and systems. Light scattering is also a very versatile tool for the characterization of nanostructures and defects. In the course of aiming for ever increasing resolution of optical devices and the need to analyze ever smaller structural features, the demands for highly resolved light scattering metrology have become extremely challenging. In this sense, “highly resolved” means: (i) measurements with high angular resolution, not just in one plane but within the entire scattering sphere, (ii) looking at optical, not just mechanical resolution, (iii) small near-angle limits, (iv) highest sensitivities close to or even below the Rayleigh scattering limit, and most recently (v) spectral resolution. Instruments for scatter measurements developed at Fraunhofer IOF to meet these demands are presented together with practical examples of application ranging from superpolished surfaces to thin film coatings. In addition to rather complex laboratory instruments, compact tools like a table-top 3D scatterometer and a CMOS-based scatter sensor are presented. Finally, we report on the development of a new instrument for spectroscopic angle resolved scatter measurements based on an OPO tunable laser.

8838-2, Session 1

Estimating hemispherical scatter from incident plane measurements of isotropic samples scattering from both bulk and surface irregularities

John C. Stover, The Scatter Works Inc. (United States); Sven Schröder, Alexander von Finck, David Unglaub, Angela Duparré, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany)

In the mid-1970’s it became apparent that incident plane scatter data could be represented by simple two or three parameter expressions. This realization made possible the generation of stray light estimation codes which are used on everything from military weapons, to telescopes, to car headlights to flat panel display systems. Almost all of these applications estimate hemispherical scatter from incident plane measurements. The author’s 2012 review of this process was limited to samples scattering just from surface roughness. In this paper hemispherical measurements are compared to calculations made from incident plane measurements using samples that scatter from bulk irregularities as well as surface scatter. The data is also analyzed to investigate reciprocity.

8838-3, Session 1

Calculating BTDF from window surface roughness

John C. Stover, The Scatter Works Inc. (United States); Vladimir Lopushenko, Lomonosov Moscow State Univ. (Russian Federation); Kashmira Tayabaly, College of Optical Sciences, The Univ. of Arizona (United States); Eugene L. Church, Consultant (United States)

The Rayleigh Rice vector perturbation theory has been successfully used for several decades to relate the surface power spectrum of optically smooth reflectors to the angular resolved scatter resulting from light sources of known wavelength, incident angle and polarization. A similar relationship should be available for the situation of a beam transmitting from a region of index greater than 1.0 into a region of unit index through an optically smooth surface. This paper presents such a relationship and compares the result to measured scatter data at two light wavelengths.

8838-4, Session 1

Use of the surface PSD and incident angle adjustments to investigate near specular scatter from smooth surfaces

Kashmira Tayabaly, Matthew B. Dubin, James H. Burge, College of Optical Sciences, The Univ. of Arizona (United States); Robert E. Parks, Optical Perspectives Group, LLC (United States) and College of Optical Sciences, The Univ. of Arizona (United States); John C. Stover, The Scatter Works Inc. (United States)

The Rayleigh Rice vector perturbation theory has been successfully used for several decades to relate the surface power spectrum of optically smooth reflectors to the angular resolved scatter resulting from light sources of known wavelength, incident angle and polarization. While measuring low frequency roughness is relatively easy, the corresponding near specular scatter can be difficult to measure. This paper discusses using high incident angle near specular measurements along with profile generated surface power spectrums as a means of checking a near specular scatter requirement. Indeed, the specification in question, a BRDF of 1.0 sr-1 at 2 milli-radians from the specular direction and at a wavelength of 1 micrometer, is very difficult to meet by conventional scatter measurements. The sample under test being an uncoated Zerodur surface with relatively high bulk scatter, it was impossible to measure scatter directly. This paper presents profilometer and scatterometer data obtained from coated and uncoated flats at several wavelengths and outlines the analysis technique used to check this tight specification.

8838-5, Session 1

Sparse microdefect evaluation system for large fine optical surfaces based on dark-field microscopic scattering imaging

Yongying Yang, Dong Liu, Shitong Wang, Pin Cao, Xiaoyu Chen, Lu Li, Lu Yan, Zhongtao Cheng, Zhejiang Univ. (China)

It is considered challenging to evaluate the sparse microdefects of large optical surfaces because the microdefects are usually of microns while the test samples are of hundreds of millimeters. Most of the existing methods encounter problems such as uncertainty and inefficiency in eyeballing, inconsequence between laser source and international standard, limitation of detecting area, qualitative but not quantitative nor standard measurement of defects, etc. In this paper, a dark-field microscopic scattering imaging system for microdefects evaluation is introduced. The test sample, which can be of meter size, is illuminated by circular spaced white LED (Light Emitting Diode) light source. The scattering lights of the surface microdefects are captured by a digital microscope, thus the dark-field microscopic images of the microdefects are obtained. Since the test samples are usually of hundreds of millimeters or larger, the DM is controlled by an X-Y translation stage to collect sub-aperture images and sub-aperture stitching is employed to

obtain the full aperture image of the test sample. To obtain quantitative evaluation of the microdefects, a group of standard defects, such as scratches, pits, etc, are grooved by electron beam exposure and ion beam etching. As a result, the surface microdefects of the large aperture test samples can be resolved with submicron resolution. In this paper, the principle of the proposed surface microdefect evaluation system will be presented and the experiment results on evaluating numerous of test samples will be given. This system can also be employed for defect evaluation of small optical components, silicon chips and other applications that have high requirements for surface defects.

8838-6, Session 2

Measurement of a large deformable aspherical mirror using SCOTS (Software Configurable Optical Tests System)

Run Huang, Peng Su, College of Optical Sciences, The Univ. of Arizona (United States); Guido Brusa, Large Binocular Telescope Observatory (United States) and The Univ. of Arizona (United Kingdom); James H. Burge, College of Optical Sciences, The Univ. of Arizona (United States)

SCOTS (software configurable optical test system), is an efficient metrology technology based on reflection deflectometry that uses only an LCD screen and a camera to measure surface slope. The surface slope is determined by triangulation knowing coordinates of the display screen, the camera and the test mirror. Some previous papers have reported the high performance of this technology in various applications, primary mirror of the Giant Magellan Telescope, refractive optics, high precision X-ray optics, etc.

In this paper, we present our recent SCOTS test results concentrated on high dynamic range measurements of low order aberrations. The varying astigmatism in the 91 cm diameter aspheric deformable secondary mirror for the Large Binocular Telescope was measured with SCOTS, requiring no null corrector. The SCOTS system was designed on axis with camera and screen aligned on the optical axis of the test mirror with the help of a 6 inch pellicle beam splitter. The on-axis design provided greater control of the astigmatism in the test. The high dynamic range of slope provided a measurement of astigmatism with 0.2 µm rms accuracy in the presence of 231 um PV aspheric departure. The simplicity of the test allowed the measurements to be performed at multiple elevation angles.

8838-7, Session 2

High-precision surface metrology of x-ray optics with an interferometric microscope

Ian Lacey, Nikolay A. Artemiev, Wayne R. McKinney, Valeriy V. Yashchuk, Lawrence Berkeley National Lab. (United States)

We describe a systematic procedure developed for surface characterization of super polished x-ray optical components with an interferometric microscope. In this case, obtaining trustworthy metrology data requires thorough accounting of the instrument's optical aberrations, its spatial resolution, and random noise. We analyze and cross compare two general experimental approaches to eliminate the aberration contribution. The reference surface approach relies on aberration evaluation with successive measurements of a high quality reference mirror. The so called super smooth measurement mode consists of subtracting two surface profiles measured over two statistically uncorrelated areas of the optics under test. The precisely measured instrument's modulation transfer function (MTF) and random noise spectrum allows us to correct the aberration-amended surface topography in the spatial frequency domain. An original MTF calibration method [Opt. Eng. 47(7), 073602 (2008)] is based on binary pseudo-random test samples specific for a particular arrangement of the microscope in use. While the developed measurement procedure is general and can be applied to various metrology instruments, the specific results presented are from a Zygo NewViewTM 7300 microscope.
Supported by the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

8838-8, Session 2

Non-contact metrology of aspheres and windows of large departure

Scott DeFisher, Edward M. Fess, OptiPro Systems (United States)

The measurement of large departure aspheres and windows is a challenge for the optics community. OptiPro systems has developed a non-contact measuring system called UltraSurf to overcome these difficulties. The UltraSurf system utilizes a single point non-contact sensor coupled with high accuracy air bearings to scan optical surfaces.

Five air bearing axes allow for the optical probe to maintain normal angles with the surface under test, and provide a smooth and accurate scan. The axes of motion allow scanning of rotationally symmetric parts such as spheres and aspheres, but also give it the freedom to perform areal surface scanning and freeform metrology. By maintaining a tangent angle with the surface, this technique allows for large surface slopes and deviation from best fit sphere to easily be measured.

Several commercial non-contact sensors have been integrated into UltraSurf. The sensors operate with different optical principles, allowing for greater flexibility of the types of surfaces to be measured. One sensor applies white-light confocal chromatic aberration for high resolution, single surface measurement. Another sensor that uses low-coherence interferometry with a 1310 nanometer light source is able to see through materials, enabling multiple surface and thickness measurements simultaneously.

Measurement of large departure aspheres and windows will be demonstrated. Cross comparison of UltraSurf data with current metrology techniques will be shown on surfaces that can be measured with multiple methods.

8838-20, Session 2

Analysis of three different measurement strategies carried out with the TII-3D coordinate measurement system

Florian Schneider, Hochschule Deggendorf (Germany)

Together with the group of interferometry based systems, coordinate measurement machines are an essential part of the metrology in the modern optical industry.

Coordinate measurement machines commonly consist of a multi axes framework. They are designed to operate in a defined three dimensional work zone, where every possible point can be reached by the measurement tool tip. This basic design principle leads to some interdependent challenges. A detailed measurement result needs a large amount of measurement points to detect even minor irregularities and short-wavelength errors. However, a rising of the amount of measurement points increases the corresponding measurement time analogous. On the other hand, the extended operation time increases the access of undesired thermal and dynamic influences, which cause multiple errors to the measurement result. Furthermore, modern production processes need rapid metrology systems to aid the machining time.

This paper discusses results obtained by operating with three different measurements in order to find an agreement between speed and certainty of the coordinate measurement machine. The topographic coordinate measurement system TII-3D had been re-developed at the University of Applied Sciences Deggendorf in the laboratory of optical Engineering and it is equipped with three different measurement strategies. The first mode, the Track Mode, operates in concentric circles on top of the surface of the object to be measured. The Spiral Mode measures along a dynamic moveable spiral line and the Sectional Mode

produces multiple cross-sections.

The results of this paper may be useful for the future design of measurement machines in general.

8838-10, Session 3

Algorithms for surface reconstruction from curvature data for freeform aspherics

ByoungChang Kim, Kyungnam Univ. (Korea, Republic of); Chunyu Zhao, Chang Jin Oh, James H. Burge, College of Optical Sciences, The Univ. of Arizona (United States)

Increasing demand for highly accurate freeform aspheric surfaces requires accurate and efficient measurement techniques. One promising possibility uses a scanning system that measures curvature variations across the part. In this paper, we develop data processing algorithms that reconstruct the surface profiles from the curvature data. The performance of suggested methods and the sensitivity to noise is diagnosed.

8838-11, Session 3

Dynamic vibration-modulated sub-aperture stitching interferometry

Hung-Sheng Chang, Chao-Wen Liang, National Central Univ. (Taiwan); Wei-Yao Hsu, Zong-Ru Yu, Instrument Technology Research Ctr. (Taiwan)

The sub-aperture testing methods have been widely used in the optical shop. It is developed to test the surface deformation of large diameter, high numerical aperture, or aspherical optical surfaces.

In this proposed research paper, we take advantage of the symmetry property of the axial symmetrical optical surfaces, and use four axis stages to measure the tested object that is optically nulled along the tangential direction. By adapting the vibration modulated phase shifting algorithm, the interferogram data is acquired on the fly without stopping the rotation motion of the tested lens during the measurement. The vibration modulated interference phase is then calculated and stitched into a global lens surface map in the least squares sense.

This method has advantages over the prior art in that it does provide the interferogram data in a much shorter acquisition time without extra hardware requirement. Thus, the interferometer can acquire hundreds of sub-aperture phase with very high resolution in a few minutes. The stitch error is then significantly decreased by increasing both the resolution of sub-aperture number and stitch overlap area.

8838-12, Session 3

Subaperture stitching performance estimation

Greg A. Smith, College of Optical Sciences, The Univ. of Arizona (United States); Chunyu Zhao, Univ. of Arizona (United States); Peng Su, James H. Burge, College of Optical Sciences, The Univ. of Arizona (United States)

Subaperture stitching extends measurements such as interferometry by combining several overlapping measurements into a single, high-accuracy estimate of the overall image. In designing a subaperture measurement regimen, there are several tradeoffs related to size, quantity and locations of subapertures within the full aperture of the test optic. Understanding how individual subaperture measurement noise couples through these parameters into errors in the final stitched map is important for estimating overall system performance. In this work, we explore parametric rules for estimating the accuracy of stitched results based on subaperture geometry parameters and noise characteristics for a self-calibrating system where both a test optic and reference optic are simultaneously determined. From these rules, we examine types of errors introduced by stitching which enables confidence estimates for the final stitched map surface quality.

8838-13, Session 3

Calculation of the reference surface error by analysing a multiple set of sub-measurements

Roland Maurer, Hochschule Deggendorf (Germany)

The interferometry is probably the most important method of measurement in the field of precision optics. An interferometric measurement is always a relative measurement. The measured parameter is the optical path difference between the reference wave front and the test wave front. Since the surface quality of the reference lens can never be perfect, the interferogram is always a combination of the reference wave front error and the test wave front error. In the case of one single measurement which covers the whole test surface it is impossible to distinguish between these error-contributions. By using the stitching principle, one obtains multiple measurements at different positions on the test surface, whereas the reference wave front error is identical in each sub-measurement. As a consequence, the error contribution of the optical system may be estimated on the basis of the sub-measurements. Therefore two separated considerations are being done. First the contribution of each sub-measurement to the calculation of the real test surface error is determined. On the other hand the reference wave front error is also included in each sub-measurement. So in the second part the contribution of each sub-measurement to the calculation of the reference surface error is checked. This approach results in two over-determined linear equation systems, one for the determination of the test surface error and one for the calculation of the reference surface error. Each sub-measurement is taken into account with its Zernike-representation. The Zernike-coefficients for the estimated reference surface are calculated with the aid of a least squares fit. The results are compared with the results from the well-known metrology stage QED SSI-A from QED technologies.

8838-50, Session 3

Advanced surface metrology for meter-class optics

Martin J. Valente, Benjamin J. Lewis, Nicholas Melena, Mark A. Smith, Arizona Optical Systems, LLC (United States); James H. Burge, Arizona Optical Systems, LLC (United States) and Arizona Optical Metrology, LLC (United States); Chunyu Zhao, Arizona Optical Metrology, LLC (United States)

Refinements in computer controlled optical surfacing allow efficient grinding and polishing of meter-class optics to accuracy limited only by the surface metrology. We present a taxonomy of metrology methods and their implementation for meter class optical components. Interferometry with computer generated holograms provides nanometer accuracy for full surface measurements of a wide range of convex and concave aspheric surfaces. For measuring off-axis and freeform aspheric surfaces, the holograms include features that provide references for alignment. Very high spatial resolution is achieved with subaperture interferometric measurements which can be stitched together to provide a full-aperture map. Scanning systems complement the capabilities of interferometry by achieving larger dynamic range and providing independent corroboration. Optical coordinate measurement machines (CMMs) provide non-contact measurements of surfaces in their ground state to guide figuring, as well highly accurate measurements of finished optics. Scanning systems for measuring flat mirrors provide excellent resolution and absolute accuracy. The performance and practical issues for this full array of measurement techniques are presented to show the relative strengths of each method.

8838-16, Session 4

Metrology measurements for large-aperture VPH gratings

Jessica Zheng, Luke Gers, Jeroen Heijimans, Australian Astronomical Observatory (Australia)

The High Efficiency and Resolution Multi Element Spectrograph (HERMES) for the Australian Astronomical Observatory (AAO) use four large apertures, high angle of incidence volume phase holographic gratings (VPHG) for high resolution 'Galactic archaeology' spectroscopy. The VPH gratings work at an angle of incidence of 67.2º and line frequencies between 2400- 3800ln/mm. The large clear aperture, 525 mm x 200 mm, the diffraction efficiency, the line frequency homogeneity, and mosaic alignment made manufacturing and testing challenging. As a result ,a new metrology system was developed at the AAO to verify the performance of these VPH gratings.

There are two basic configurations for the new metrology system; diffraction efficiency and line frequency measurement. The diffraction efficiency setup is comprised of a goniometer, a stable white light source coupled to a 200 mm aperture off-axis collimator, and collecting optics coupled to a spectrum analyser. The line frequency metrology system has two different configurations each using the goniometer and high coherence laser. One configuration, a double pass system using a point source microscope (PSM) with a return flat and the other configuration using a 140mm diameter refracting telescope coupled to a CCD camera.

The measured VPH grating performances are in good agreement with vender's measurement results and they are close to the designed values.

8838-17, Session 4

Optical testing with computer generated holograms: comprehensive error analysis

Chunyu Zhao, James H. Burge, Arizona Optical Metrology LLC (United States)

Interferometry with computer generated holograms (CGHs) has become the industry standard for accurate measurements of aspheric surfaces. The CGH is a diffractive optical element that can be designed to create virtually any phase or amplitude distribution, and can be accurately manufactured using methods and equipment developed for integrated circuit production. Surface measurements with nanometer level precision can be performed using accurately well-calibrated equipment. This paper provides a systematic analysis of all significant sources of error for CGH metrology, including sources of pattern error, substrate irregularity and calibration, and system alignment.

Limitations in the design, fabrication and alignment of the CGH lead to errors in the interferometric measurements. In the design process, a CGH phase function is obtained which ideally produces null fringes in the measurement of an aspheric surface. Any deviation from null leads to error in the measurement. In the fabrication process, the first step is to encode the CGH phase function to pattern data that the writing machine recognizes. Then the pattern is written onto a substrate. For phase type CGH, additional steps are taken to etch patterns into the substrate. Each of these steps introduces error which could be estimated. In addition, the substrate the CGH pattern is made on introduces error as well. And the substrate can be calibrated, and the residual error can be estimated. In the final use of the CGH, any alignment error of the CGH introduces a wavefront error that degrades the measurement accuracy. The errors are described, quantified, and combined to provide a comprehensive assessment of the measurement accuracy.

8838-18, Session 4

Holographic radius test plates

Quandou Wang, Ulf Griesmann, National Institute of Standards and Technology (United States)

Radius and sphericity, the local departure of a near spherical surface from the best-fit sphere, together fully characterize a spherical surface. The sphericity of a spherical surface can be measured easily with a Fizeau interferometer that is equipped with a Fizeau objective, or transmission sphere. Measuring the radius of of a spherical surface is generally more difficult. If a measurement with low uncertianty is required, the radius bench method must be used. A part with a spherical surface is moved in an interferometer with spherical test wavefront along the optical axis from a position at which the test beam focus is at the part surface (cat's eye), to a position at which the test beam focus is at the center of curvature (confocal). The distance between these two positions is the part radius.

The lowest measurement uncertainty for the radius can be achieved when the distance is measured with a displacement measuring laser interferometer. The radius bench method is flexible and it can be used to measure radii of spherical surfaces in a wide range, at the expense of considerable complexity of the measurement setup.

For many applications this flexibility is not needed, because the radius of a surface is known approximately and only the departure of the radius from a nominal value must be determined. We describe a test method that uses a zone plate with two nested areas that is positioned in the test beam of a spherical Fizeau interferometer. The zone plate at the center of the nested zone plate generates a focus at the test part surface, whereas the -1st diffraction order of the outer zone plate is a wavefront that is confocal with the test part.

When the test part radius is the same as the nominal radius, the fringes in both areas are nulled at the same distance of the test part from the zone plate. The defocus term of a Zernike surface height map is calculated in both zone plate areas for several positions around the cat's eye position of the inner zone lens. The radius error of the spherical surface can be calculated from the defocus term in the confocal area at the position of zero defocus in the cat's eye area of the zone plate.

8838-19, Session 4

Wavefront retrieval for cross-grating lateral shearing interferometer based on differential Zernike polynomial fitting

Tong Ling, Dong Liu, Lei Sun, Zhongtao Cheng, Yongying Yang, Zhejiang Univ. (China)

In experiments of inertial confinement fusion (ICF), the thickness uniformity of capsule and the density uniformity of deuterium-tritium (DT) ice are both key to successful ignition, while the cross-grating lateral shearing interferometer (CGLSI), which is accurate and insensitive to disturbance, can be employed to test the density distribution of DT ice precisely. In this paper, a wavefront retrieval method for CGLSI based on differential Zernike polynomial fitting is presented. Fast Fourier transform technique is employed to get the frequency spectrum of the interferogram obtained by CGLSI. By performing inverse fast Fourier transform (IFFT) of the +1 order spectrum in both X and Y directions, it is possible to extract shearing wavefronts from the interferogram in both two orthogonal directions. Utilizing differential Zernike polynomial fitting method, we are capable of integrating two shearing wavefronts in X and Y directions together and retrieving the wavefront under testing. In the process of solving Zernike coefficients, the characteristics of differential Zernike orthogonal polynomials should be taken fully into account in mathematical modeling. To avoid the retrieval error introduced due to matrix mutation, the determination of discrete grid number and aperture shape must be in line with the theory that Zernike orthogonal polynomials are orthogonal over a unit circle as well. The result of simulation analysis shows that the wavefront retrieval method for CGLSI based on differential Zernike polynomial fitting is correct and accurate, and the root-mean-square error of this method is less than $\lambda/15$.

Freeform surface-machining error-compensation method for ultra-precision slow tool servo diamond turning

Chun-Chieh Chen, Chien-Yao Huang, Wei-Jei Peng, Yuan-Chieh Cheng, Zong-Ru Yu, Wei-Yao Hsu, Instrument Technology Research Ctr. (Taiwan)

Recently, the optical freeform surface has been widely applied in optoelectrical industry, such as head-up display, astigmatism contact lens, progressive additional lens and f-theta lens for laser printer. To generate these freeform surfaces, ultra precision machining methods including Fast tool servo, slow tool servo, fly cutting and diamond milling methods are mainly used. Slow tool servo (STS) has the advantages of no extra attachment and fast setting-up in comparison with the other machining method. In the previous research, we have developed a model of three dimensional tool shape compensation for generating 3D tool path in slow tool servo diamond turning.

STS is one kind of facing operation, the cut-depth (Z-axis) is a function of radial (X-axis) position and work spindle angular position (C-axis). As the work-piece rotates, the diamond tool oscillates in and out of Z-axis motion to generate the required surface. Z-axis motion speed and accuracy are constrained by the frequency response of linear motor. When the more distance of Z-axis motion sets, the higher following error generated. Therefore, the form error increases with large surface sagitta and tangential slope. In this study, we presented a compensation method to improve the surface error. And the experiment result shows that surface form error has been compensated from 3μm to less than 1μm by the compensation method.

8838-39, Session PMon

FEM analysis of hot-pressing process of aspheric glass P-SK57 lens

Yongjian Zhu, Tongji Univ. (China); Jingxin Na, Jilin Univ. (China); Yu Wang, Zhejiang Univ. of Science and Technology (China); Anhu Li, Tongji Univ. (China); Yanan Zhi, Shanghai Institute of Optics and Fine Mechanics (China); Yufeng Fan, Zhejiang Univ. of Science and Technology (China)

Lens molding has become the promising technique to conduct mass produce of aspheric glass lens. It overcomes some disadvantages of traditional grinding or turning methods, such as high cost, low efficiency, unstable accuracy, and so on. Up to now, the lens molding process has been looked on as one of the reliable methods in fabrication of aspheric glass lens. However, in real production, one has found that it's hard to control the molding parameters, e.g. molding temperature, molding period, molding speed and pressing pressure, etc. Therefore it's necessary to develop the specific molding processes for a certain glass material. In this paper, through FEM simulation, the lens molding process has been conducted as for glass of Schott P-SK57. Three stages of heating, pressing and annealing have been simulated separately to achieve the relative processing parameters. Based on three different pressing temperatures of 510°C, 520°C and 530°C, it's known that the heating duration is taken as 450s and the best pressing temperature is at 530°C. Meanwhile, the pressing velocity can be chosen as 0.1mm/s. After pressing at 530°C, the residual stress is only 5.22mpa. In filling ratio, it's only 96.07% at 510°C; 98.51% at 520°C and 99.02% at 530°C. It proves that the filling effect can meet the molding requirements at 530°C. Therefore, it's suggested that the best molding temperature could be taken as 530°C with pressing velocity of 0.1mm/s for low-melting P-SK57.

8838-40, Session PMon

New design of null screens to simplify the correspondence during the quantitative evaluation of optical surfaces

Martin I. Rodriguez Rodriguez, Alberto Jaramillo-Núñez, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Jose Rufino Díaz-Uribe, Univ. Nacional Autónoma de México (Mexico)

We have been working in a method for testing fast aspheric convex surfaces with flat null screens in an array of LCD's, based on the null screen principles accordingly; i.e. We have demonstrated qualitatively that using three LCD's forming a triangular prism, we can evaluate aspheric fast surfaces instead of the traditional test of cylindrical null screen. This setup of LCD's has the advantage of display a series of 3 null screens for sampling an optical surface simultaneously, where in the ideal case, the position of the drop-shaped spots should be forming a regular square array of points in the image plane. However, due to typical problems of illumination and directionality with the transmitted light through the LCD's, some spots on the image are missing which complicates the correspondence between centroids and coordinates of the null screens, which is important for the quantitative evaluation in the numerical integration procedure used. In this paper we propose the design of null screens with reference marks, which provide unambiguous correspondence. Specific designs include some strategic color and position coding to ease the image spots identification. We show the method as used during the quantitative evaluation of a spherical steel ball.

8838-41, Session PMon

Development of a prototype of the GMT fast steering mirror

Young-Soo Kim, Ju Heon Koh, Hwa Kyoung Jung, Ho June Jung, Pradipta V. Biswas, Korea Astronomy and Space Science Institute (Korea, Republic of); Myung K. Cho, National Optical Astronomy Observatory (United States); Ho-Soon Yang, Korea Research Institute of Standards and Science (Korea, Republic of); Ho-Sang Kim, Kyoung-Don Lee, Institute for Advanced Engineering (Korea, Republic of); Hyo-Sung Ahn, Gwangju Institute of Science and Technology (Korea, Republic of); Won Hyun Park, College of Optical Sciences, The Univ. of Arizona (United States); Sug-Whan Kim, Yonsei Univ. (Korea, Republic of); Narae Hwang, Yoon-Kyung Seo, In-Soo Yuk, Byeong-Gon Park, Korea Astronomy and Space Science Institute (Korea, Republic of)

Giant Magellan Telescope (GMT) Fast Steering Mirror (FSM) is a common secondary mirror comprised with seven segments. FSM has a fast focal ratio of 0.65 and is 3.2 m in total diameter whose segment is 1m in diameter. The surrounding six segments except the center one are off-axis mirrors. FSM also contains an implemented tip-tilt mechanism which compensates image degradations caused by wind disturbances and structure jitter.

Korea Astronomy and Space Science Institute is developing a prototype of the FSM together with collaborators in Korea and USA. The prototype is a full-size FSM segment, and it is divided into two features functionally; an off-axis mirror and a test-bed for tip-tilt actuation. The off-axis mirror with a diameter of 1.06m is being fabricated. Light-weighting of the mirror at the backside was performed first. Polishing of the front surface is finished and figuring is in progress. Several types of tip-tilt test-beds have been produced by integrating together with a dummy aluminum mirror, three axial supports, a lateral support, and various test-bed frames. Each component has been verified, and assembled test-beds are being verified. In this paper, we present the progress of the prototype development, and future works.

8838-42, Session PMon

The optical performance test of a lightweighting primary mirror of an aerospace Cassegrain telescope

Wei-Cheng Lin, Instrument Technology Research Ctr. (Taiwan)

The optical remote sensing instrument (RSI) of FORMOSAT-5 satellite is an aerospace cassegrain telescope with 450 mm diameter clear aperture. In order to meet both thermal and weight requirement, the primary mirror is using Zerodur and light weighted as the ratio about 50 %. For this mid-large lightweight mirror, the optical performance test is a modern technique whether in the manufacture or assembly process. While in the optical measurement, there are some inconsiderable measurement errors caused erroneous judgments for the mirror. It's difficult to specify the measured astigmatism caused from the form error after polishing or surface deformation by the external force from the supporter or mechanical mount. In this paper, the optical performance test called bench test with different supporter compared with vertical and horizontal setup is presented. After measurement, a novel algorithm to analyze the astigmatism caused from the gravity effect, form error from manufacture and the deformation from the mounting or supporter was presented.

8838-44, Session PMon

Practical absolute optical surface metrology and novel applications in adaptive optics

Eric E. Bloemhof, National Science Foundation (United States)

Practical application of a recently-devised absolute metrology scheme based on comparison of transversely-shifted frames from a commercial Fizeau interferometer (E. E. Bloemhof, Opt.Lett. 35, 2346, 2010) will typically require interleaving data sets with spatial frequency sampling incommensurate with the pixel spacing. These procedures are presented, and it is shown, somewhat counterintuitively, that no large degradation of spatial resolution results. While obviously useful in characterizing laboratory optics, where the new technique appears simpler and more sensitive than the classical 3-flat technique, there are also interesting applications in adaptive optics systems, such as diagnosing non-common-path errors. These and other applications are presented and analyzed.

8838-45, Session PMon

Incorporating skew into RMS surface roughness probability distributions

Mark T. Stahl, H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States)

The standard treatment of RMS surface roughness data is the application of a Gaussian probability distribution. This handling of surface roughness ignores the skew present in the surface and overestimates the most probable RMS of the surface, the mode. Using experimental data we confirm the Gaussian distribution overestimates the mode and application of an asymmetric distribution provides a better fit. Implementing the proposed asymmetric distribution into the optical manufacturing process would reduce the polishing time required to meet surface roughness specifications.

8838-46, Session PMon

A study on the characteristics for ultra-precision machining technique using single-diamond turning machine

Wookang Kim, Geonhee Kim II, Geunman Ryu III, Meyeongsang Huh, Korea Basic Science Institute (Korea, Republic of)

In this paper, the cutting effect of Al-alloy using a single diamond turning machining is applied to make on aerospace spherical mirror. The ultra precision cutting has been done in the thermal vacuum chamber and the experimental tryout was minimized using the optimum processing conditions which were determined design of experiments. In this study, we considered three influenced factors on the surface roughness such as cutting speed, feed rate and depth of cut. The purpose of this research is to find the optimum machining conditions for cutting reflector apply the SPDTM technique to the manufacturing of ultra precision optical components of Al-alloy spherical reflector. The cutting force and surface roughness are measured according to each cutting conditions. We achieved the spherical mirror in the 300mm diameter with the surface roughness and the shape accuracy. We also show that the values can be applied to make the Al-alloy spherical reflector using diamond turning machine to perform cutting processing.

8838-47, Session PMon

Refractometer based on a double slit optofluidic interferometer. Prism refractometer.

Sergio Calixto-Carrera, Ctr. de Investigaciones en Óptica, A.C. (Mexico)

Basic optofluidic elements are composed of spherical cavities, microchannels and other structures. Liquids can flow through the structures of these optofluidic elements. Here we propose a refractometer that consists of two hollow microchannels where fluids can be inserted. When light illuminates the double channel an interference pattern is shown in the far field. If a liquid with different refractive index is inserted in one microchannel the interference pattern presents a linear movement. It is possible to find a calibration curve relating the liquid refractive index as a function of the number of fringes that had passed through a point reference.

8838-48, Session PMon

Improvement of active lap in the grinding of a 1.8m honeycomb primary mirror

Haitao Liu, Zhige Zeng, Fan Wu, Bin Fan, Yongjian Wan, Institute of Optics and Electronics (China)

The computer controlled active lap (CCAL) is used to grind a 1.8m honeycomb primary mirror now. One problem which is not totally solved of CCAL is the edge effect, which also exists in many other fabricating methods. To reduce the CCAL's edge effect, we analyze the pressure distribution on the contact face between lap and mirror by finite element method (FEM). A new method is proposed to calculate the pressure curve from FEM results. A simplified model is used to approximate the pressure curve along the mirror's radius when active lap covers the mirror's center hole. The const-linear (C-L) model is used to describe the pressure curve when active lap overhang at the mirror's out edge. The contact status between lap and mirror is also considered in this paper, and its influence is taken into the material removal rate's calculation. The API's T3 laser tracker is used to measure the mirror's surface shape and check the theory model's correctness. The results that we have got by now and the problems that still exist are reported in this paper.

8838-49, Session PMon

High-accurate subaperture testing

Fengtao Yan, Institute of Optics and Electronics (China) and Univ. of the Chinese Academy of Sciences (China); Bin Fan, Xi Hou, Fan Wu, Baiping Lei, Institute of Optics and Electronics (China)

We introduced a high accurate subaperture testing method. This stitching method could reduce the interferometers deviation to the stitching results. This high accurate subaperture testing is determined by the data processing technique based on multiangle averaging method and Zernike polynomial fitting method. This technique does not require any assumptions about the surfaces under test. This high accurate subaperture testing method can obtain not only the full absolute shape of the large mirrors but also the reference mirror surface shapes.

The error that the reference affect to the stitch result is only variations and rotationally symmetric of the reference surface deviation. First we describe the detail theory to get the reference surface deviation. Then we provide a comparative experimental study on the high accurate subaperture stitching testing with the QED Technologies method.The experiment results shows that the reference mirror surface shapes could be calibrated and the root mean square (RMS) between the two methods are ~0.80nm and ~0.87nm in the residual figures.

8838-21, Session 5

Fast manufacturing of E-ELT mirror segments using CNC polishing

Caroline Gray, Robert Evans, Nathan R. Field, Paul C. Rees, Steven Waine, Tony Fox-Leonard, Glyndwr Univ. (United Kingdom); David D. Walker, Glyndwr Univ. (United Kingdom) and Zeeko Ltd. (United Kingdom) and Univ. College London (United Kingdom); Guoyu Yu, Glyndwr Univ. (United Kingdom) and Univ. College London (United Kingdom); Wilhelm Messelink, Zeeko Ltd. (United Kingdom) and Univ. College London (United Kingdom)

We report on the first-ever demonstration of grinding and polishing full-size, off-axis aspheric, mirror segments as prototypes for an extremely large telescope, processed entirely in the final hexagonal shape. We first describe the overall strategy for controlling form and mid spatial frequencies, at levels in the vicinity of <10nm RMS surface. This relies first on direct CNC grinding of the base-form of these 1.4m segments, using the Cranfield BoXTM machine. The segments are then mounted on a bespoke support system, and CNC polished on a Zeeko IRP 1600 machine using a variety of custom tooling. We overview the full-aperture and sub-aperture metrology techniques used to close the process-loop and certify quality, all of which operate with the segment in-situ on the IRP1600. We then focus on the pristine edge-definition achieved by the combination of specialist tooling and tool control; results never previously demonstrated on full-size pre-cut hexagonal segments. Finally, the paper discusses the feasibility of scaling the process to deliver 931 segments in seven years, as required for the E-ELT project.

8838-23, Session 5

The development of stacked core technology for the fabrication of deep lightweight UV-quality space mirrors

Gary W. Matthews, Exelis Visual Information Solutions (United States); Charles S. Kirk, Steven P. Maffett, ITT Exelis (United States); Calvin E. Abplanalp, Jet Propulsion Lab. (United States); H. Philip Stahl, Michael R. Effinger, NASA Marshall Space Flight Ctr. (United States)

The ASTRO2010 Decadal Survey stated that an advanced large-aperture ultraviolet, optical, near-infrared (UVOIR) telescope is required to enable the next generation of compelling astrophysics and exoplanet science; and, that present technology is not mature enough to affordably build and launch any potential UVOIR mission concept. Under Science and Technology funding, NASA's Marshall Space Flight Center (MSFC) and ITT Exelis have developed a more cost effective process to make up to 4m monolithic spaceflight UV quality, low areal density, thermally and dynamically stable primary mirrors. A proof of concept mirror was completed at ITT Exelis and tested down to 250K at MSFC which would allow imaging out to 2.5 microns. The parameters and test results of this concept mirror will be shown. The scale-up process will be discussed and the technology development path to a 4m mirror system by 2018 will also be outlined.

8838-24, Session 5

Advancements in asphere manufacturing

Scott DeFisher, OptiPro Systems (United States)

Aspheric optics can pose as a challenge to the manufacturing community due to the surface shape and level of quality required. The aspheric surface may have inflection points that limit the usable tool size during manufacturing, or there may be a stringent tolerance on the slope for mid-spatial frequencies that may be problematic for sub-aperture finishing techniques to achieve. As aspheres become more commonplace in the optics community, requests for more complex aspheres have risen.

OptiPro Systems has been developing technologies to create a robust aspheric manufacturing process. Contour deterministic microgrinding is performed on a Pro80 or eSX platform. These platforms utilize software and the latest advancements in machine motion to accurately contour the aspheric shape. Then the optics are finished using UltraForm Finishing (UFF), which is a sub-aperture polishing process. This process has the capability to adjust the diameter and compliance of the polishing lap to allow for finishing over a wide range of shapes and conditions. Finally, the aspheric surfaces are qualified using an OptiTrace contact profilometer, or an UltraSurf non-contact 3D surface scanner. The OptiTrace uses a stylus to scan across the surface of the part, and the UltraSurf utilizes several different optical pens to scan the surface and generate a topographical map of the surface under test. This presentation will focus on the challenges for asphere manufacturing, how OptiPro has implemented its technologies to combat these challenges, and provide surface data for analysis.

8838-25, Session 5

Designing, fabricating, and testing freeform surfaces for space optics

Xue-jun Zhang, Changchun Institute of Optics, Fine Mechanics and Physics (China)

Freeform surfaces provide more design freedoms to imaging system without introducing new types of aberrations, therefore better performance can be expected.

First in this talk, the design theory of imaging optical system with freeform surfaces was introduced and issues such as tolerancing , manufacturability were discussed; Based on that, fabrication and testing of freeform surfaces were discussed; Particularly?deterministic polishing techniques including CCOS, Magnetic Medium Assisted and Ion Beam polishing were presented in detail.

Since testing is critical to make high accuracy freeform surfaces, the talk also addressed several testing techniques for different fabrication processes varying from rough grinding to fine polishing. Computer Generated Hologram (CGH) design and implement to measure large freeform mirrors were discussed in detail.

Finally, some real world examples were given to show the advantages of freeform surfaces in space optics.

8838-26, Session 5

Ultra-high-precision alignment technology for lens manufacturing used for high-end optics

Thomas Sure, Technische Hochschule Mittelhessen (Germany); Sebatian Schiffner, Hexagon Metrology GmbH (Germany)

We present a way to enhanced common used alignment-technologies by using digital image processing. This work is motivated by the continuously increasing demand for high-end optics. During the last years the surface lens quality has been continuously improved. Today the image quality is more determined by the manufacturing tolerances for the mechanical interface which is responsible for decenter and tilt of the lenses respectively the subgroups. Some of the aberrations are directly linked to the decenter of the lenses, Coma for example. Hence it is necessary to realize the subgroups with tolerances below 1 micron. To determine the decenter of a lens an auto collimation telescope is used to image the reflex of the lens surfaces onto a detector, commonly a half covert photodiode. Rotating the lens generates a sinusoidal signal, which is evaluated by a lock-in amplifier to drive two actuators to adjust the alignment chuck. Typical internal reflections caused by stray light for example disturb the current procedure in such a way that is impossible to get a stable alignment process. Digital image processing allows us to fix these problems with image recognition. We will demonstrate how a modified auto collimation telescope in combination with the developed software algorithms made the manufacturing process more accurate, faster and useable for a broad spectrum of lenses. It has been proofed by some thousand diverse lenses that with these new technique subgroups can be centered within 0.25 microns.

8838-27, Session 6

Development of hybrid fluid jet/float polishing process

Anthony T. Beaucamp, Chubu Univ. (Japan) and Zeeko Ltd. (United Kingdom); Yoshiharu Namba, Chubu Univ. (Japan); Richard R. Freeman, Zeeko Ltd. (United Kingdom)

On one hand, the CNC “fluid jet polishing” process consists of pumping a mixture of water and abrasive particles to a converging nozzle, thus generating a polishing spot that can be moved along a tool path with tight track spacing. But whilst tool path feed can be moderated to ultra-precisely correct form error on freeform optical surfaces, surface finish improvement is generally limited to ~1.5nm rms (with finer abrasives).

On the other hand, the “float polishing” process consists of a tin lap having many concentric grooves, cut from a flat by single point diamond turning. This lap is rotated above a hydrostatic bearing spindle of high rigidity, damping and rotational accuracy. The optical surface thus floats above a thin layer of abrasive particles. But whilst surface texture can be smoothed to ~0.1nm rms (as measured by atomic force microscopy), this process can only be used on flat surfaces.

This paper reports on the development of a novel finishing method that combines the advantages of “fluid jet polishing” (i.e. freeform corrective capability) with “float polishing” (i.e. super-smooth surface finish of 0.1nm rms or less). To come up with this new “hybrid” method, computational fluid dynamic modeling of both processes is being used to characterize abrasion conditions and adapt process parameters of experimental polishing equipment, including: (1) geometrical shape of nozzle, (2) position relative to the surface, (3) dynamic control of inlet pressure. This new process is aimed at next generation X-Ray / Gamma Ray focusing optics.

8838-28, Session 6

Roughness improvement in Active Fluid Jet Polishing (A-FJP) by optimisation of the polishing pin

Manuela Falter, Christine Wünsche, Rolf Rascher, Markus Schinhaerl, Hochschule Deggendorf (Germany)

A testing series was carried out to determine the distribution of the surface roughness across the width of the polishing area when the A-FJP tool is moved on the workpiece surface without overlapping. For the testing series, N-BK7 was used as sample with a diameter of 60 mm. The track of the A-FJP tool is clearly visible. The polishing pin had a diameter of 6 mm and the nozzle had an eccentricity of 1.5 mm. The rotational speed of the nozzle was 1407 rpm and the feed rate was 13.6 mm/min. A standard cerium polishing fluid was used. The pressure at the nozzle was 1 bar.

A Zygo NewView 7200 white light interferometer was used to measure the surface roughness at 5 points across the width of the polishing track. In the second testing series a 2 mm hole was drilled through the centre of the polishing pin so that the polishing fluid not only could stream through the annular gap between pin and nozzle but also straight through the pin.

As the surface roughness could be significantly improved during the testing series with the perforated polishing pin, it stands to reason that the surface roughness in an entire polishing procedure where overlapping takes place may be reduced as well. Further investigations in this area are currently going on to find optimum process conditions between the different parameters, in particular the track distance. If the track distance could be increased, the process time would decrease which in turn would benefit an enhanced economical process.

Results from a simple optimisation of the polishing pin by drilling a hole through its centre have shown a significant improvement of the surface roughness. Additional testing series are currently under way to find out coherences between pin geometry, velocities, track pitch and polishing fluid condition, in particular fluid pressure.

Fourth-generation aluminum optics performance

Keith Carrigan, Ankit Patel, L-3 Communications Tinsley Labs. Inc. (United States)

While post-polish has previously been shown to greatly enhance the surface quality, surface roughness, and surface figure of single-point diamond turned Aluminum mirrors, the field of bare Aluminum polishing continues to advance. New results demonstrating improvement in mid-spatial frequency errors and methods for adapting to a wider range of Aluminum materials constitute the next generation of polished Aluminum mirrors. These results show new levels of surface finish, correlated with BRDF measurements. Complimentary enhancements have been made by achieving new levels of precision in the placement of the optical axis relative to datum features, enabling significant alignment time savings.

8838-30, Session 6

Novel reactive chemical mechanical polishing technology for fabrication of SiC mirrors

Rajiv Singh, Arul C. Arjunan, Kannan Balasundaram, Sinmat, Inc. (United States)

Silicon carbide (SiC) is considered an excellent material for high performance optical applications because of its superior properties including extremely high specific stiffness (E/ρ), high thermal conductivity and excellent dimensional stability. However, silicon carbide is next only to diamond in hardness and is chemically inert. Both the precision

machining required for shaping and the conventional finishing processes (lapping, polishing) of SiC mirrors is extremely slow making it expensive to produce a light weighted, super-polished SiC substrate. In addition, diamond which is typically employed to achieve reasonable polishing rate, creates sub-surface damage, high density of scratches and other polishing defects which leads to mid and high spatial frequency errors. This talk will focus on a novel reactive chemical mechanical polishing process for SiC mirrors which increases the removal rate by several folds over conventional process at the same time reduce the rms roughness to <0.5 nm. Challenges associated with polishing of polycrystalline SiC and multiple phase material e.g. grain delineation will be discussed. The effect of various components, chemical and mechanical, of the reactive polishing slurry on surface roughness will be discussed.

8838-31, Session 6

Super-smooth optical fabrication controlling high-spatial frequency surface irregularity

Javier G. Del Hoyo, Dae Wook Kim, James H. Burge, College of Optical Sciences, The Univ. of Arizona (United States)

Modern advanced optical systems often require challenging high spatial frequency surface error control during their optics fabrication processes. While the surface figure (>>1mm scales) error can be controlled by directed material removal processes such as small tool figuring, surface finish (<<1mm scales) is controlled with the polishing process. For large aspheric optical systems, surface figure irregularities of a few millimeters in scale may cause serious performance degradation in terms of scattered light background noise and high contrast imaging capability. The conventional surface micro roughness concept in Root Mean Square (RMS) over a very high spatial frequency range (e.g. RMS of 0.5 by 0.5 mm local surface map with 500 by 500 pixels) is not sufficient to describe or specify these surface characteristics. For various experimental polishing conditions, we investigate the process control for high frequency surface errors with periods up to ~2-3mm. The Power Spectral Density of the finished optical surfaces has been measured and analyzed to relate various computer controlled optical surfacing parameters (e.g. polishing pressure, lap stroke speed, polishing compounds) with the high spatial frequency errors on the surface. The experiment-based optimal polishing conditions and processes producing a super smooth optical surface while controlling surface irregularity at the millimeter range are presented.

8838-33, Session 7

Accurately measuring dynamic coefficient of friction in ultraform finishing

Dennis E. Briggs, Samantha Echaves, Brendan Pidgeon, Nathan Travis, Jonathan D. Ellis, Univ. of Rochester (United States)

UltraForm Finishing (UFF) is a deterministic subaperture computer numerically controlled grinding and polishing platform designed by OptiPro Systems. UFF is used to grind and polish a variety optics from simple spherical to fully freeform, and numerous materials from glasses to optical ceramics. The UFF system consists of an abrasive belt around a compliant wheel that rotates and contacts the part to remove material. This work aims to accurately measure the dynamic coefficient of friction (μ), how it changes as a function of belt wear, and how this ultimately affects material removal rates. The coefficient of friction has been examined in terms of contact mechanics and Preston's equation to determine accurate material removal rates. By accurately predicting changes in μ, polishing iterations can be more accurately predicted, reducing the total number of iterations required to meet specifications. We have established an experimental apparatus that can accurately measure μ by measuring triaxial forces under translating loading conditions. Using this system, we will demonstrate μ measurements for UFF belts during different states of their lifecycle and assess the material removal function from spot diagrams as a function of wear. Ultimately, we will use this system for qualifying belt-wheel-material combinations to develop a spot-morphing model to better predict instantaneous material removal functions.

8838-34, Session 7

Analysis and modeling of tribology effects in conventional glass polishing

Daniel Waechter, Olaf Dambon, Fritz Klocke, Fraunhofer-Institut für Produktionstechnologie (Germany)

Conventional or chemo-mechanical polishing represents the polishing technology most often applied for manufacturing precision glass optics. It is applied on various machine types and for all kinds of geometries. But it still represents the manufacturing step with the lowest process stability.

This work deals with the analysis and descriptive modeling of the tribology effects and contact conditions occurring in the process area. The polishing process is assumed as a hydrodynamic system. The model aims for an estimation of the occurring fluid between pad and surface. Its effects on the interaction between the components of the polishing system (pad, slurry, and lens) are discussed. Therefore, existing models are reviewed and combined by the hydrodynamic modeling approach. Secondly, the theoretical considerations are validated by experiments on a specialized tribometer. With this test bench the effects of the viscosity of the slurry, the polishing parameters as well different pad properties on the contact conditions were investigated. It was found, that an increased viscosity as well as roughness of the pad surface shift the transition point between mixed and liquid friction. A focus is put on the polishing pad and the effects of its properties. Four types of the commonly used polyurethane pads were characterized. The process and wear behavior were investigated on a synchrospeed polishing machine, which will be discussed finally based on the findings of the tribometer tests.

The understanding of the contact condition forms the basis for developing stable polishing conditions and improved polishing systems, for example polishing pads.

8838-35, Session 7

Four-axis single-point diamond machining of arrays of miniature lenses

Brian P. McCall, Tomasz S. Tkaczyk, Rice Univ. (United States)

Four-axis single point diamond machining (4-axis SPDM) is a diamond machining technique that executes the spiral toolpath in (X,Y,Z) coordinates of a micro-milling operation while holding the tool in contact with the surface of the lens for the duration of the cut by means of a 4th axis - the C axis. This feature of 4-axis SPDM allows feed rates to be increased without affecting the surface roughness of the finished part, unlike micro-milling. Following errors and inertia become the limiting factor in fabrication speed. This work explores the effect of these dynamics on lens shape and image quality for various geometries of lenses, including spheres, aspheres, convex, and concave lenses. Feed rates are pushed above the previously reported 500 mm/min rates to their limit while maintaining diffraction limited form errors. Plastic materials such as Zeonex 480R and polystyrene Rexolite 1422 are used to create optical components for these experiments. Their surface measurements and imaging properties are shown to confirm the high precision obtained while characterizing the fabrication speeds of the 4-axis SPDM technique.

8838-37, Session 7

A comparison of equivalent moldable glasses

Alan Symmons, LightPath Technologies, Inc. (United States)

There are over one hundred types of glass that are sold as moldable grades. These moldable glasses are manufactured by a limited number of suppliers; each manufacturer with his own grade and designation. Many of these grades can be found to have groupings across the manufacturers, indicating possible equivalency. Equivalency of materials is an important consideration for an optical system as it would eliminate dependency on a single source, and generate cost competition. In order to establish optical equivalency it is necessary to establish significant similarity between materials. This paper compares moldable glass grades from several equivalent glass types from different manufacturers both theoretically and experimentally. Experimental data is based on precision glass molding of the same lens using different but equivalent grades of glass and using standard lens criteria for comparison. Conclusions on whether specific glass types are truly equivalent are then established.

Sunday - Monday 25–26 August 2013

Part of Proceedings of SPIE Vol. 8839 Dimensional Optical Metrology and Inspection for Practical Applications II

8839-1, Session 1

Spatial fringe analysis based on FFT using only two speckle pattern in ESPI *(Invited Paper)*

Yasuhiko Arai, Kansai Univ. (Japan)

Speckle interferometry is one of important deformation measurement methods for an object with rough surfaces. Many methods have been already reported. In this paper, a high resolution new measurement method which requires only two sheets of speckle patterns in analyzing process is proposed. In the method, a new optical system which uses a plane wave-front as the reference beam of the speckle interferometer is employed. In the fringe analysis by using the optical system, the deformation information and the bias components of the speckle patterns can be clearly separated in frequency domain. A pair of real- and imaginary-part components concerning the information of deformation can be extracted by Fourier transform in the fringe analysis processing. The real part of the information before deformation is shifted on the frequency domain in order to create carrier fringes. Furthermore, the specklegram is calculated between the shifted real part of the speckle-pattern before deformation and the non-shifted real part of the speckle-pattern after deformation. The fringe image, which includes the spatial carrier-information, is given as specklegram, and is filtered. The phase map is calculated by using spatial fringe analysis method from the filtered deformed carrier fringes as specklegram. From experimental results, it is confirmed that the new method can analyze a deformation process with a convex and/or concave phase distribution in a high resolution power, and that the resolution power of the measurement is much higher than 1/150 of the light source of the optical system.

8839-2, Session 1

Real-time uniaxial profilometry using contrast detection by polarization camera

Yukitoshi Otani, Shuhei Shibata, Fumio Kobayashi, Utsunomiya Univ. (Japan); Yasuhiro Mizutani, Univ. of Tokushima (Japan); Toru Yoshizawa, NPO 3D Associates (Japan)

We propose a real time measurement of three-dimensional surface shape using contrast detection of uniaxial detection by a polarization camera. All distance information of z-direction can be determined by measuring the contrast of projected grating pattern that can be calculated phase-shifting method. A telecentric optical system is employed to keep the magnification of the object image captured by a CCD camera by changing the focus distance. A shadow less measurement of the object's area is archived by using a uni-axial system. The liquid crystal digital shifter is a powerful tool to analyze the contrast that is made arbitrary intensity and frequency distribution. Surface profiles are measured to demonstrate this method.

8839-3, Session 1

Improve dithering technique for 3D shape measurement: phase vs intensity optimization

Junfei Dai, Zhejiang Univ. (China); Beiwen Li, Song Zhang, Iowa State Univ. (United States)

We recently introduced binary dithering techniques to the 3D shape measurement field. These methods have drastically enhanced the binary defocusing technique. Yet, the dithering techniques, after all, are developed to represent arbitrary grayscale images with fewer bits through simple matrix operation. There is not optimization method developed for sinusoidal structured patterns. Therefore, it has great potential to further improve the dithering technique by taking advantage of the inherent sinusoidal structures. The optimization can be performed with in phase or intensity domain. The former is to approximate the ideal phase with the binary patterns after they are slightly blurred; and the latter is to approximate the ideal sinusoidal waveform with the binary patterns. The question to ask is: which optimization method will be more robust? This paper presents a thorough comparison between these two methods. Since a 3D shape measurement system utilizing a digital fringe projection technique, the phase quality ultimately determines the measurement quality, and thus these methods are compared in phase domain. Both simulation and experiments find that the phase-based optimization method can generate high-quality phase under given conditions. However, this method is sensitive to the amount of blurring (or defocusing). On contrast, the intensity-based optimization method can consistently generate high-quality phase with various amounts of defocusing. Therefore, it seems that the intensity-based optimization method has more practical value than the intensity-based optimization method in the 3D shape measurement field.

8839-4, Session 1

Dual resolution imaging for metrology applications

Kevin G. Harding, Daniel C. Gray, GE Global Research (United States)

Many applications require a fine measurement to be made over a small area, but with reference to a much larger area. The ability to inspect a large surface, then to zoom in to a small area is valuable in many application ranging from bridges to turbines. However, the need to switch lense or re-point a lens can make such inspection cumberson. This paper discusses an optical method that permits an instantaneous switch from a wide view to a close up of any area within that wide view, without the need to change lenses or repoint the optical system. We will discuss the possible application of the method, as well as the limitations inherent to the concept.

8839-5, Session 2

Surface profile measurement of a diffraction grating by a laser beam scanning interferometer using sinusoidal phase modulation *(Invited Paper)*

Osami Sasaki, Takuya Kubota, Samuel Choi, Takamasa Suzuki, Niigata Univ. (Japan)

It is difficult in interferometric metrology to maintain high spatial resolution over a large measurement region. Interferometric microscope measurements yield high resolution, but only over a small area. Other conventional interferometric systems can measure large areas, but they fail to provide the necessary spatial resolution. High spatial resolution over a large field of view is a very important characteristic for large size objects. In this paper this characteristic is achieved by scanning a focused laser beam over an object surface and a reference mirror surface in an interferometer for surface profile measurement. A collimated laser beam from a laser diode is incident into an electric-optic phase modulator (EOM) to generate sinusoidal phase-modulation between the two orthogonal polarization components. The beam passing through the EOM is reflected by a rotating mirror and moves over a surface of a polarization beam splitter with the help of a lens to produce a focused beam scanning over an object surface and a reference mirror surface. When the object is a diffraction grating, the beam focused on to the grating is not diffracted strongly. This effect leads to an easy and exact measurement without an imaging system in the interferometer. The two focused beams are reflected by the surfaces and travel back along the same path as the original beam. A confocal optical system with a lens and a pinhole is used to produce a sinusoidally phase-modulated interference signal on a photo-multiplier detector. In experiments, the scanning speed of the focused beam was 20 m/s, and the frequency of the sinusoidal phase-modulation was 10 MHz. The spatial resolution of the surface profile measurement was 2.0 microns over the measurement area of 15mm. The measurement results indicated that the measurement error was less than 5nm.

8839-6, Session 2

Diffractive optics calibrator

Wenrui Cai, Ping Zhou, Chunyu Zhao, James H. Burge, The Univ. of Arizona (United States)

Errors and uncertainties in the fabrication processes of diffractive optics will produce wavefront phase errors. When applying the finished part in optical testing, accuracy of the measurements will be affected consequently. In this paper, we describe the diffractive optics calibrator, a new device for measuring the local duty-cycle and etching depth of a binary diffractive optics used in transmission. The measurements can be used to assess uniformity of the diffractive optics for calibration or quality control.

According to scalar diffraction theory, diffraction efficiency is a function of both the duty-cycle and the etching depth of a binary linear grating. We utilize this relationship in the device. From a collimated laser beam, the intensities of multiple diffraction orders were captured by wide field of view camera lens. The duty-cycle and etching depth are determined simultaneously by fitting the measured intensities to a parametric model. This device is able to scan through the whole area of the diffractive optics and generate a wavefront phase error map, which is due to duty-cycle and etching depth variations. The measurements are validated with a lateral scanning white-light interferometer.

The system is capable of measuring the percentage of duty cycle variation that causes 1 nm PV phase errors. This method is advantageous since it can be carried out rapidly with accurate and repeatable results, does not damage the sample, and uses low-cost equipment.

8839-7, Session 2

Comparison between LCOS projector and DLP projector in generating digital sinusoidal fringe patterns

Beiwen Li, Song Zhang, Iowa State Univ. (United States)

In digital fringe projection technique, digital sinusoidal fringe patterns of good quality need to be generated in order to perform an accurate measurement. There are two major ways to generate digital sinusoidal fringe patterns: focused-sinusoidal-patterns (FSP) method and defocused-binary-patterns (DBP) method. The performances of both FSP and DBP technology are subject to the properties of the projector used. Digital-light-processing (DLP) and liquid-crystal-on-silicon (LCOS) are two widely used digital projection technologies which have drawn great attention from researchers. They have different ways to generate grayscales. For DLP technology, it works with digital micro mirrors and the different grayscales are generated by time integration, while for LCOS technology, it works with liquid crystals instead of individual mirrors. It has already been studied that for DLP technology, when FSP method is applied, it suffers from nonlinear gamma effect as well as varying phase error over different exposure times, while DBP method does not have such drawbacks. Then a question is raised: is there any difference for LCOS technology? Do the aforementioned problems become ameliorated or worse? This paper presents a comparison between LCOS and DLP projector for FSP method, DBP method as well as projector nonlinear gamma. Experiment depicts that for FSP method, LCOS projector has advantages over DLP for its smaller nonlinear gamma effect and no need for precise synchronization. While for DBP method, DLP projector is superior to LCOS projector for its generated patterns of higher contrast ratio.

8839-8, Session 2

Characterization of the optical components fabricated by femtosecond pulses in transparent materials

Lina Mazule, Simona Liukaityte, Vilnius Univ. (Lithuania); Vytautas Sabonis, Vilnius Univ. (Lithuania) and Workshop of Photonics (Lithuania); Titas Gertus, ALTECHNA Co. Ltd. (Lithuania); Mindaugas Mikutis, Vilnius Univ. (Lithuania) and Workshop of Photonics (Lithuania); Domas Paipulas, Tomas Puod?i?nas, Valdas Sirutkaitis, Vilnius Univ. (Lithuania)

The femtosecond laser pulses found wide application in modification of the refractive index or surface topography of the transparent materials. These modifications created new generation of optical components: diffraction gratings and radial polarization elements fabricated in fused silica, solar cells and etc. The operation and quality of these components depend on laser and processing parameters. Sensitive and multiple methods are required for characterization of these optical components and optimization of the modification process.

We present the optical methods used for characterization of the diffraction gratings and radial polarization elements fabricated in fused silica by high repetition rate femtosecond KGW:Yb laser. The methods used for characterization of the components with refractive index modification were transmission and diffraction measurements at fixed and tunable wavelengths, and total integrated scattering (TIS). Transmission and diffraction measurements were performed by photodetectors and CCD camera using tunable radiation from OPA “Topas”. Solar cells with modified surface by femtosecond pulse ablation were investigated by TIS and Volt-Ampere measurements.

The combined characterization methods were sufficient for modification process optimization and allowed creation of the Bregg gratings with efficient in range from 55 to 90% and low scattering losses.

The current increase is registered with growth of the scattering loses in the solar cells. Volt-Ampere measurements showed that there is great improvement of scattering light comparing laser unaffected zone and laser fabricated zone with 1.1 uJ pulse energy and 10 um between pulses (from 4.04% to 21.9%).

8839-10, Session 3

Coaxial phase-shifting laser diode interferometer based on pulse modulation *(Invited Paper)*

Takamasa Suzuki, Takuma Serizawa, Osami Sasaki, Samuel Choi, Niigata Univ. (Japan)

The optical interferometer is an important device in precision manufacturing. The wavelength tunability of laser diodes (LDs) is a useful parameter to consider when configuring a compact interferometer. Several types of interferometers that employ LDs have been proposed and used in practical applications. Although the LD wavelength is generally modulated using a stepwise, triangular, or sinusoidal signal, this direct modulation degrades the measurement accuracy because the intensity of the interference signal varies with the injection current.

We previously proposed a phase-shifting (PS) interferometry that uses a pulse current for direct modulation. The wavelength change that occurs just after the injection of a pulse current is used to modulate the phase of the interference signal. This technique enables accurate phase measurement as it realizes a large wavelength change with no change in optical power. In the optical system, however, it requires the use of two separate interferometers to determine the amount of phase shift accurately. Also it takes time for capturing images if no ultrafast camera is available. These restrictions make the system vulnerable to external disturbances.

In this paper, we propose a pulse-modulated PS interferometer, in which two coaxial interferometers and an undersampling technique are employed. The former improves the robustness of the optical system and the latter shortens the time of image capture. Several measurements on a flat mirror confirmed a measurement accuracy of ~20 nm.

8839-11, Session 3

Research on a fiber Bragg grating sensor structure for health monitoring of coal mines

Yong Zhao, Yue Dong, Zhongqiang Li, Northeastern Univ. (China)

The coal mine tunnel collapse problem is very common and its damage is very serious. At Present, few researches are done about the engineering design of the optical fiber sensor and the analysis of the sensor monitoring system. In this paper, a displacement sensor using fiber grating technology was designed, which could be used to prevent the problem of coal mine tunnel collapse by monitoring the coal mine tunnel roof displacement. Firstly, The Finite Element Analysis was demonstrated to simulate the stress and displacement of coal mine tunnel roof to determine where to install the sensor. Then the characteristics of the fiber Bragg grating sensor were analyzed in detail and the sensor structure was designed according to the actual requirements in the coal mine. At last, the feasibility of the whole system was experimentally verified. The specific sensor structure design was as follows: the mine tunnel roof were fixed with two anchors, a spring and a two-period fiber grating were placed in series to achieve displacement measurement between two anchors. In this structure, one end of the spring was connected to the first anchor, and the other end was connected with the two-period fiber grating. What's more, the second end of the fiber Bragg grating was connected to the second anchor. The cross-sensitivity of temperature and displacement issue with FBG sensors could be eliminated by this special design. The measuring range of 100mm and the measurement accuracy up to 0.1mm could be obtained with the proposed sensor.

8839-12, Session 3

Using fiber-optic probes for photoluminescence and evaluation of an InGaN/GaN epi-wafers

Woohyun Jung, Jongki Kim, Hang-Eun Joe, Byung-Kwon Min, Kyunghwan K. Oh, Yonsei Univ. (Korea, Republic of)

Photoluminescence (PL) is one of the methods used for analyzing the optical characteristics of LED epi-wafers. For components in solid-state lighting such as GaN-based LEDs, the use of an LED structure configuration on a patterned sapphire substrate has shown to be highly effective in improving light-extraction efficiency. We constructed a simplified PL measurement system based on fiber-optic probes to enhance the efficiency of PL analysis. An excitation beam was launched from 405nm laser using the lensed fiber fabricated by splicing a single-mode fiber and a polymer-coated coreless silica fiber. For high resolution, a multi-mode file detector tip was manufactured using a focused ion beam. The 38μm diameter core of this tip is coated with a 30nm Au film, with a 1.0μm diameter centered hole. The relative importance of both contributions and the achievable lateral resolution are strongly dependent on the geometry and scanning conditions. A computer-controlled xyz nano-positioning stage was used to move the samples. With this system, we successfully obtained PL morphology data from peak intensity, peak wavelength (photon energy) and FWHM of the emission spectra at each position on the epi-wafers. The proposed fiber-optic PL system could become a compact and multifunctional alternative method to pre-existing PL systems. We also expect that further optimization of the focused beam diameter could improve the spatial resolution of the system, and hope that a completed system will analyze surface condition, alloy composition change, variation in layer thicknesses and layer disorder / grading effects.

8839-13, Session 3

OCT based on multi-frequency sweeping Fizeau Interferometer with phase modulating method

Samuel Choi, Osami Sasaki, Tomoya Watanabe, Takamasa Suzuki, Niigata Univ. (Japan)

Recently, the demands for tomographic vibration measurements with sub-nanometer accuracy using the optical coherence tomography (OCT) technique have increased in the biomedical field. We proposed a Multi-frequency sweeping Fizeau-type interferometer (MFS-FI) for the OCT. The multi-frequency sweeping by a variable Fabry-Perot filter (FPF) permits detection of high-order low-coherence interferometric signals in the Fizeau interferometer. The sinusoidal phase modulation (SPM) technique was utilized to detect accurate interference amplitude and phase distributions of back scattered light from surfaces of a sample. The experimental setup of the MFS-FI consisted of a super luminescent diode with center wavelength and bandwidth are 840 nm and 30 nm respectively, collimator, the FPF, a Fizeau interferometer and a 2-dimensional CCD image sensor. The interference image from a sample is focused by using a lens system. The FPF in which a cavity length was scanned by a Piezo-electric (PZT) actuator produced the multi-frequency sweeping for depth scan. The SPM was performed by modulating the path difference using a PZT to detect the interferometric phase. The SPM signal was driven by a signal generator of which the modulation frequency was synchronized with a flame rate of the CCD. The samples were glass plates and tissues fixed with formalin and embedded in paraffin vibrated with a frequency of few ten kHz. By using the MFS-FI with the SPM, we could measure the tomographic 3-dimensional volume of the samples and estimated its vibrating surface displacement with an accuracy of nanometers.

8839-14, Session 4

Multimodal industrial inspection in power engineering and building industries: new challenges and solutions *(Invited Paper)*

Malgorzata Kujawinska, Warsaw Univ. of Technology (Poland)

This presentation will cover digital image correlation, thermography, structured light methods with spectral and roughness analysis (I might add also local interferometric sensors). I will also present several interesting examples of usage these techniques in power engineering and building industries.

8839-15, Session 4

Automated cylindrical mapper using chromatic confocal measurement

Esmaeil Heidari, Kevin G. Harding, Robert W. Tait, GE Global Research (United States)

Characterization of a surface shape and finish has been vital for the manufacture of precision parts. Overall profile, surface finish and waviness of a part can be measured in two ways, contact and non-contact. In the contact method a stylus is dragged on the surface of a part to measure the profile and texture of the part for quantifying the surface characteristics. Non-contact methods applied to precision metrology include: microscopy, interferometry, chromatic confocal microscopy and laser profiling such as structured light methods. The chromatic confocal method offers flexibility because of its fiber optics probes that can be manipulated to accommodate many sample geometries. This flexibility provides a wide range of possible analysis dimensions such as cylindrical shapes of holes and the potential to provide both surface roughness and shape. This paper will discuss the setup and testing of a system specifically for measuring cylindrical shaped parts and present the performance of the technology as a precision metrology tool.

8839-16, Session 4

Calibration of high-aspect ratio quality control optical scanning system

Aneliya Karadzhinova, Timo Hilden, Jouni Heino, Helsinki Institute of Physics (Finland); Maria Berdova, Aalto Univ. and Micronova Nanofabrication Ctr. (Finland); Rauno Lauhakangas, Francisco Garcia, Eija Tuominen, Helsinki Institute of Physics (Finland); Ivan Kassamakov, Univ. of Helsinki (Finland)

Gas electron multiplier (GEM) detectors are widely used in contemporary high energy physics experiments, e.g. at the European Organization for Nuclear Research and Antiproton and Ion Research in Europe experiments. The GEM is a detector containing an etched holes in the polymer foil coated with a thin metal layer on both sides which is able to achieve high amplification gains and performance at low cost, even under harsh radiation conditions. The foil holes have with nominal diameter of 70 ±5 µm and 140 µm between centre separations.

A high quality assurance is needed to guarantee a long lifespan for the detectors in the severe radiation environment. Mapping of the defects connecting two or more holes is important phase when determining the usability of a foil for detector application.

Optical Scanning System (OSS) with scanning area of 1000 x 1000 mm was realized at the Helsinki Detector Laboratory for control of the quality of GEM foils.

A silicon test sample containing sets of 10 x 10 numbered etched wells with nominal diameter of 70 ±1 µm was produced and was calibrated using factory calibrated Stylus profiler (KLA – Tencor P15). The wells dimensions and the expanded uncertainty were calculated with 95% confidence level, as it is required by the ISO Guide for Expression of Uncertainty in Measurement.

The silicon sample was measured with the OSS in nine different positions of the scanning area. The results were analyzed and uncertainty and the corrections were calculated according to the ISO requirement.

8839-17, Session 4

One-shot measurement of the air-liquid interface effect by a spectral-domain low-coherence dynamic light scattering technique

Toshiharu Watarai, Toshiaki Iwai, Tokyo Univ. of Agriculture and Technology (Japan)

The Brownian motion of particles close to the interface between air and liquid is affected by the hydrodynamic interaction due to Stokes drag force. The particles move considerably slower in this region than in the free diffusive region far from the fluid surface. The experimental setup was constructed as an optic-fiber Michelson interferometer with a low-coherence light source and a high-speed spectrometer. Applying the principle of the spectral-domain optical coherence tomography to the low-coherence dynamic light scattering, we can realize non-scanning operation of the reference mirror in the depth range. Therefore, the spectral-domain low-coherence dynamic light scattering technique is proposed to analyze the dynamics of the Brownian particles simultaneously and seamlessly at the measuring positions from the far region to the near region. The 1-vol% suspension of the polystyrene latex particle with the sub-micron radius was used as a sample medium in the experiments. The diffusion coefficients can be estimated by fitting numerically a negative-exponential function as a model function to the measured amplitude auto-correlation function of time-varying scattering amplitude. As a result, the experimental diffusion coefficients show that the Brownian motion is suppressed in the region close to the air-liquid interface, increases consistently with the distance from the interface, and is in free Brownian motion far from the liquid surface. The effectiveness and the applicability of the proposed new dynamic light scattering technique can be fairly well confirmed by the experiments.

8839-18, Session 4

Development of blood vessel search system using near-infrared light for laparoscopic surgery

Kazuyuki Narita, Eiji Nakamachi, Yusuke Morita, Akeo Hagiwara, Doshisha Univ. (Japan)

Our objective in this study is to develop a miniature and high accuracy automatic 3D blood vessel searching system, which will be introduced in the laparoscopic operation with the minimally invasive surgery. Now, the conventional optical system used in the laparoscopic surgery have many difficulties of blood vessel imaging and detection, because the peripheral bio-tissue located around the blood vessel disturbs the light wave propagation, disperses and refracts. Consequently, only unclear image is obtained. We develop a new blood vessel detecting system by using Near-Infrared (NIR) light, two CMOS camera modules and a comprehensive image processing technique, which is implemented in the laparoscope pipe with 25mm in diameter. We adopt the stereo method for the searching system to determine 3D blood vessel location. The blood vessel visualization system adopts hemoglobin's absorption characterization of the NIR light, which has high permeability for the bio-tissue and absorbency for the hemoglobin. A sharpening process is employed to improve the image quality of original ones, through the LoG filter and the un-sharp-mask processing. 2D location of the blood vessel is calculated by luminance distribution of the image and its depth is calculated by the stereo method. A validity of our blood vessel visualization and 3D detecting system was examined through the comparison with the imaging and detecting results of organization phantoms, which embedded at known depths under the surface. Experimental results of depth obtained by our detecting system showed good agreements with the given depths, and the availability of this system is confirmed.

8839-19, Session 4

Inch-scale high-throughput metrology of graphene and patterned graphene oxide

Dennis Pleskot, Zafer Mutlu, Jeffrey Bell, Isaac Ruiz, Mihrimah Ozkan, Cengiz S. Ozkan, Univ. of California, Riverside (United States)

Inch-scale high throughput characterization of graphene sheets was achieved by fluorescence quenching microscopy (FQM). This technique proved to be highly scalable compared to other common methods such as Raman spectroscopy, SEM, and TEM. Whereas other techniques can take days to image inch-scale samples, FQM requires only a few hours. Along with this, fluorescence quenching caused minimal, if any, damage to graphene samples, demonstrating the non-destructive nature of this method. In contrast, other techniques such as Raman, SEM, and TEM, are well known for being highly destructive imaging processes. Thus, fluorescence quenching was determined to be a highly advantageous characterization technique for large-area graphene compared to the more common methods currently in use. FQM also displayed effectiveness at imaging the contrast between graphene and graphene oxide, demonstrating an ability to generate distinct contrast intensities for pristine graphene, pristine graphene oxide, defects, and multilayer regions within graphene oxide. Contrast differences due to fluorescence quenching were further analyzed by Raman spectroscopy,

which confirmed the existence of these different intensity regions and thus validated FQM as a reliable characterization process. Since large-area graphene has several potential applications in solar cell devices and macroscale mechanical support structures, and graphene oxide is an important precursor in producing graphene, FQM characterization of these materials is a significant step toward making these applications a reality.

High-resolution real-time 3D shape measurement on a portable device

Nikolaus L. Karpinsky, Morgan Hoke, Vincent Chen, Song Zhang, Iowa State Univ. (United States)

Recent advances in technology have enabled the acquisition of high-resolution 3D models in real-time though the use of structured light scanning techniques. While these advances are impressive, they require large amounts of computing power, thus being limited to using large desktop computers with high end CPUs and sometimes GPUs. This is undesirable in making high-resolution real-time 3D scanners ubiquitous in our mobile lives. To address this issue, this work describes and demonstrates a real-time 3D scanning system that is realized on a mobile device, namely a laptop computer, which can achieve speeds of 30fps 3D at a resolution of 640x480 per frame. By utilizing a graphics processing unit (GPU) as a multipurpose parallel processor, along with a parallel phase shifting technique, we are able to realize the entire 3D processing pipeline in parallel. To mitigate high speed camera transfer problems, which typically require a dedicated frame grabber, we make use of USB 3.0 along with direct memory access (DMA) to transfer camera images to the GPU. To demonstrate the effectiveness of the technique, we experiment with the scanner on both static geometry of a statue and dynamic geometry of a talking participant in front of the system.

8839-21, Session 5

Uni-axial inner profile measurement

Toshitaka Wakayama, Saitama Medical Univ. (Japan); Toru Yoshizawa, NPO 3D Associates (Japan)

Recently, the requirement of an inner profile measurement has been rapidly increasing to get quality assurances in the fields of industry and medicine. Using a ring beam device our group has proposed the inner profile measurement based on optical sectioning technique. This measuring instrument is very powerful tool to evaluate their inner surface profile and their condition of industrial samples. As advanced evaluations, there is required to measure the inner surface profile of samples at uni-axis. To meet this requirement, we have proposed a uni-axial inner profile measurement based on the technique of shape from focus. In our experiment, we employed a He-Ne laser, a variable focus lens, a conical mirror and a CCD camera. The laser beam was incident into the conical mirror after passing through the variable focus lens. The shape of laser beam was transformed from a point beam to a disk-like beam. The focus of the disk-like beam can be controlled by current value of the variable focus lens. A CCD camera captured the intensity distribution of optical sectioning profile on the inner surface of the sample. The intensity distribution captured by CCD camera became a Gaussian profile along the current value. As this result, the radius distribution on a crossed sectioning profile can be determined. In this manuscript, we have shown some experimental results as demonstrations.

8839-22, Session 5

On-machine laser triangulation sensor for precise surface displacement measurement of various material types

Klemen Žbontar, LPKF Laser and Elektronika d.o.o (Slovenia); Matjaž Mihelj, Univ. of Ljubljana (Slovenia); Boštjan Podobnik, LPKF Laser & Electronics AG (Slovenia); Franc Povše, LPKF Laser and Elektronika d.o.o (Slovenia)

The paper presents a custom-designed laser triangulation based metrology system, which enables high precision surface displacement measurement of various material types with a single sensor configuration. Laser structuring applications require material surface alignment relative to the laser focus position, where fabrication conditions are optimal. The measurement system utilizes a high-quality UV wavelength laser beam (primarily used for structuring purposes) with automatic control of its intensity. The laser source operates in a continuous wave (CW) mode during the measurement process, whereas the UV wavelength enables measurement of transparent materials. Robust displacement measurement of various material types was solved by introducing a new approach of structured light projection and its centroid detection. A high resolution 2D galvanometric scanning system is used for dynamic symmetrical pattern projection, which is proven to reduce the effects of material surface related errors and speckle noise. Furthermore, a “double curve fitting” (DCF) centroid detection algorithm, where Gaussian curves are fitted to radial cross sections of the acquired pattern, and an ellipse is fitted to their peak positions, was introduced. The method includes subsurface scattering compensation, which proves crucial for translucent material measurement, where incident light penetrates into the material surface and causes uneven light intensity distribution of the acquired pattern. Experimental results have shown that the metrology system is robust to laser intensity variation and material type, with measurement bias lower than 50 μm and standard deviation lower than ±6.3 μm for all materials. The developed probe has been integrated into commercial LPKF laser structuring systems.

8839-23, Session 5

Adaptive control system for improvement of contrast in interferograms

Nicolas Veloz, Jesús E. González-Laprea, Rafael Escalona, Univ. Simón Bolívar (Venezuela)

The present work consists of the development proposal of an adaptive control system to compensate the reduction of the contrast in interferograms caused by mechanical vibrations presented in a mirau based interference microscopy system using a low-speed camera as the only sensor. The control scheme generates random signals that are injected during the integration time of the camera through a piezoelectric in order to change the phase of the interferometer, Each image obtained by the low-speed camera has different control signals injected during the integration time. The contrast of each image is evaluated and if the contrast is improved, the signal injected during that image is adjusted to seek for a better improvement. The best signals collected, are added to the control signal, which is applied to the system after the adaptation process is over. This control scheme was implemented and proved to be able to find signals capable to compensate the main frequency components of the vibration in the system, the maximum contrast increment obtained was about 11%

8839-24, Session PMon

Full-field transmission-type angle deviation microscopes

Ming-Hung Chiu, Ming-Hung Tsai, National Formosa Univ. (Taiwan)

We proposed a three-dimensional (3-D) microscope with a magnification of 250X based on the principle of angle deviation microscopy for measuring the 3-D profile of transparent materials. When a parallel beam passing through a specimen, the angle of light after passing each test point will be deflected due to the slope of surface or/and the change of refractive index. The small deflective angle can be acquired using an angular sensor made of a parallelogram prism at the critical angle. Thus, the surface height is proportional to the deflective angle and the reflectivity of the prism. Using two CCDs located at the image planes to detect the image intensities on conditions of TIR and the critical angle, respectively, the profile of reflectivity is obtained and can be transformed into the 3-D profile of the test specimen. In our experiment, the lateral and vertical resolutions can be demonstrated within submicron and 1 nm, respectively.

Conference 8840: Optical Modeling and Performance Predictions VI

Thursday 29–29 August 2013

Part of Proceedings of SPIE Vol. 8840 Optical Modeling and Performance Predictions VI

8840-22, Session PMon

Mathematical modeling analysis on a small and compact two-dimensional CGLSI interference system

Lei Sun, Dong Liu, Tong Ling, Yongying Yang, Zhejiang Univ. (China)

When using interference wave front to detect density field, it is better to have an interference system which is small and compact so that different directions of wave fronts can be obtained to reconstruct the density field to be detected. A two-dimensional CGLSI (Cross Grating Lateral Shearing Interferometer) system which consists of a two-dimensional cross grating and a two-dimensional order-selecting window used as a filter is presented in this paper. Lateral shearing interferogram of two orthogonal directions (X and Y) each other can be obtained by using this system. With the advantage of anti-vibration and no reference surface, lateral shearing interferometer is suitable to inhibit external environment disturbance. In this paper, analysis and simulations have been conducted on grating constant from geometrical optics and physical optics using Fresnel approximation method respectively based on lateral shearing rate, windows' distance in two-dimensional order-selecting window and layout of the system which concludes the best option for grating constant is . The most optimized design of size and distance for windows in two-dimensional order-selecting window has been carried out on the basis that complex amplitude distribution can go through the filter so that there is no distortion on wave front. All designs have gone through computer simulation and fit into the requirements for the designs.

8840-23, Session PMon

Optical design of non-image optical engine with local-dimming effects via liquid crystal optics and laser light source

Yi-Chin Fang, National Kaohsiung First Univ. of Science and Technology (Taiwan)

The research demonstrates an optical design of non-image optical engine with liquid crystal optics and laser light source, which will deliver the effects similar to local dimming effects from backlight unit . Firstly, in order to achieve high contrast similar to local dimming effects from backlight system design, we employs primary colours of RGB light of laser which is mixed with a X-cube. Secondly, this design employ RGB laser as light sources. With assistance of microscanning technique and liquid optics array, varied contrasts could be presented on illumiated plane thanks to special optical design of each laser source arrays and digital signal processing.This is a completely new design which takes advantage of not only less heat interference and minimization of volumetric size of optical engine but also up to 1:100 contrast if applied to DLP projector. The simulation work reveals the performance and contrast of new developed projector reach success. if applied to DLP projector, The optical design reaches light uniformity is 86.6 % and light energy efficiency is near 40%. local dimming produced by liquid optical element will significantly improve contrast of projector up to 70%.

8840-1, Session 1

Hybrid fast Hankel transform implementation for optics simulation

Paul K. Davis, NASA Ames Research Ctr. (United States)

The most compute intensive part of a full optics simulation, especially including diffraction effects, is the Fourier transform between pupil and image spaces. This is typically performed as a two dimensional fast discrete transform. For a nearly radially symmetric system there are advantages to using polar coordinates, in which case the radial transform becomes a Hankel transform, using Bessel functions instead of circular functions. However, there are special difficulties in calculating and handling Bessel functions. Several solutions have been proposed. We present a hybrid Hankel transform which divides the range, calculating a portion using Bessel function approximations but converting most of the range into a one dimensional Fourier transform which can be handled by standard methods.

8840-2, Session 1

Frequency noise in spectral lineshape of 780-nm GaAsP/GaInP quantum-well lasers for inertial sensor applications

Joseph P. Bebe Manga Lobe, III-V Lab. (France); Bernard P. Orsal, Institut d'Electronique du Sud (France)

On one hand, 100 µm aperture broad area devices achieve at 20°C a continuous wave (CW) output power of more than 4 W per facet. On other hand, we demonstrated excellent performances on Fabry-Perot ridge-waveguide lasers with a threshold current of 35 mA, emitting up to 120 mW per facet, in single lateral mode at 780 nm. We already achieved an output power of 20 mW with a small spectral linewidth of less than 1 MHz on a DFB laser.

We present here the results on a new and systematic investigation of the low frequency noise of such laser structures, in order to better understand and improve their performances.

By using an appropriate current source and very low noise voltage amplifier (10-19 V2/Hz at 10 Hz), we can measure the intrinsic Terminal Electrical Noise (TEN), due to the fluctuations of the laser voltage. The measurements have been performed for low frequency (1Hz < f <100 kHz) and different laser currents (around the threshold current, above and at high laser current). On broad band area lasers, we obtained a very low 1/f level noise (10-13 V2/Hz at 1 Hz) due to optical gain fluctuations and active region noise (shot and thermal noise). The white noise level is about 10-18 V2/Hz . The corner frequency between 1/f and white noise is about 3 KHz, which is a good result for this kind of structures. Electrical noise measurements will be interpreted by using lasers noise theory.

8840-3, Session 1

Nth Stokes evolution due to SRS in single mode fibers

Rafael S. Lara, Ctr de Investigación e Innovación Tecnológica (Mexico); José Alfredo Alvarez-Chávez, Ctr. de Investigación e Innovación Tecnológica (Mexico); Lelio de la Cruz May, Univ. Autónoma del Carmen (Mexico)

In this work, the evolution of the nth analytical solutions of traditional Raman equations including numerical simulation and experimental results is done. In the experiment a 8.6 Km single mode fiber was pumped with an ytterbium doped fiber laser system (FL) in CW regime at 1064-nm in a free running configuration. We showed that it is possible to obtain up to the nth power thresholds and maximum power for each Stokes by using compact analytical solutions such as first approximations in an arguably simple, quick process.

A comparison of different technical analysis of Raman phenomenon was done. We showed how long the analytical and simulation results are approximated to experimental results. The parameter in comparison was power thresholds and maximum power for each Stokes. The comparative graphics have been done in 2 y 3D to show the evolutions of Stokes.

8840-4, Session 1

Circulation and concentration of s- and p-polarized light in two-dimensional compound grating

Young Uk Jung, Andrii B. Golovin, David T. Crouse, The City College of New York (United States)

Two-dimensional compound gratings (2dCGs) are capable of π-radian difference phase resonances (PRs). Circulation and concentration of p- and s- polarized incident beam of the light upon 2dCG metal structures are studied. In prior work, it has been shown that PRs can occur for p- and s-polarized light in one-dimensional compound gratings. In contrast, the structure studied in this work has two asymmetric holes in the unit cell, each filled with a material of high dielectric permittivity (ε=10.84) and can support PRs in 2dCGs in the 8 GHz to 12 GHz spectral range. Due to asymmetry within the system, the two apertures react differently to the incident beam and support PRs that are resonantly excited within the grooves. It is shown that PRs occur in 2dCGs with similar characteristics of 1dCGs, such as having narrow bandwidths, high Q values, and high concentrations of electromagnetic fields. However, PRs occurring on 2dCGs have a benefit of manipulating light in more numerous and compelling ways as compared with 1dCGs. As the incident light excites waveguide cavity modes, the fields in the desired neighboring cavities in 2dCGs are coupled by circulations of counter-propagating modes and the π -radian phase differences produce a concentration and narrowband inversion of the transmissivity/opacity. The dependencies of bandwidth and wavelength of the PRs on structural and material properties, polarization of the incident beam, as well as the Poynting vector profiles are described. Applications include narrow bandwidth optical filters, light trapping, antireflection coatings, waveguiding structures, and electromagnetically induced transparency.

8840-5, Session 2

Ray-tracing-based simulation of stray-light correction for Geostationary Ocean Color Imager

Eunsong Oh, Korea Institute of Ocean Science & Technology (Korea, Republic of) and Yonsei Univ. (Korea, Republic of); Jinsuk Hong, Samsung Thales Co., Ltd. (Korea, Republic of) and Yonsei Univ. (Korea, Republic of); Sug-Whan Kim, Yonsei Univ. (Korea, Republic of); Ki-beom Ahn, Seongick Cho, Korea Institute of Ocean Science & Technology (Korea, Republic of) and Yonsei Univ. (Korea, Republic of); Joo-Hyung Ryu, Korea Institute of Ocean Science & Technology (Korea, Republic of)

Image mosaic technique is widely used in a field of remote sensing research. However, in case of Geostationary Ocean Color Imager's (GOCI's) mosaic image which is consist of 16 slot images, the radiance level discrepancy was noticed in the cloudy circumstance next to each other slot when acquiring the imagery data in the low Sun elevation angle. We provided, in this study, the in-depth stray light analysis results in order to find out this discrepancy phenomenon, and performed the image restoration with simulated stray light bias.

Stray light analysis as the first step was completed with ray tracing technique based on ASAP program, and we suggested that unwanted radiations from the Earth bright target or the atmosphere such as cloud are major candidates of stray light in the problematic images. For embodying GOCI operational concept, we constructed the Integrated Ray Tracing model consisting of the Sun model as a light source, a target Earth model, and the GOCI optical system model.

In the second step, we investigated the stray light pattern at each slot image including unwanted random source from out of field, and then constructed the simulated mosaic bias image reached at the detector plane. In the simulated bias, the ray path followed the procedures that light travels from the Sun and it is then reflected from the Earth section of roughly 2500km * 2500km in size around the Korea peninsula with 16 slots.

Lastly, we corrected the acquired image with subtracting weighted stray light pattern bias in the third step. The real acquired image was selected UTC-03 image at 16th, October, 2012. In addition, verification was performed to compare the difference among slot boundaries.

8840-6, Session 2

Efficient automatic computation of veiling glare from scatter and ghosts by a simple modification to Monte-Carlo ray tracing

Alan W. Greynolds, Ruda-Cardinal, Inc. (United States)

Veiling glare is a somewhat obsolete term referring to stray light from an in-field extended source bleeding into adjacent dark regions of the image. In most systems ghost reflections and scatter from the contaminated or imperfectly polished optical surfaces are the main culprits. Standard stochastic or deterministic methods for calculating scattered light from out-of-field sources are cumbersome in this domain. On the other hand, basic Monte Carlo ray tracing is straightforward. Its implementation in the GelOE optical engineering software is based on a fast hybrid physical-optics/geometrical-optics technique for surface scatter. However, a prohibitive number of rays are still required to get accurate results. Instead of the standard ray-splitting and importance-sampling modifications to make it more efficient, a much simpler one is proposed and then applied to a representative lens system, resulting in a 100 to 1000 fold reduction in the number of rays required for the same accuracy.

8840-7, Session 2

Revival of the dark core in scattered optical vortices

Salla Gangi Reddy, Ashok Kumar, Shashi Prabhakar, Ravindra P. Singh, Physical Research Lab. (India)

Optical vortices are getting a lot of attention due to their applications in optical manipulation and quantum information. Here, we have experimentally observed the reconstruction of the dark core in scattered optical vortices through the rotating ground glass (RGG) plate. In this, we have generated optical vortices using computer generated hologram and a spatial light modulator. Vortices are passed through the RGG plate and scattered optical vortices are focused with a plano-convex lens of focal length 10cm. The scattered optical vortices do not show a dark core immediately after the RGG plate or the lens. However, the far-field intensity distribution (at focus) of scattered light has a dark core at its center. The diameter and the darkness of core are independent of the speed of the RGG plate i.e. the coherence of scattered light. This has been observed by the line profiles of far-field distributions of scattered vortex with a particular order at different speeds of the RGG plate. A study of the line profiles of scattered vortices of different orders shows that the diameter of the dark core increases with the increase in the order of vortex. These results follow the theoretical results of Mei and Korotkova [Opt. Lett. 38, 91-93]. We have also studied the variation of focal length as a function of distance of the lens from RGG plate. The focal length decreases when lens is moving away from RGG plate.

8840-8, Session 3

Basic approach to define signal-to-noise ratio for adjacent pixels for an uncooled micro-bolometer FPA detector

Ulas Kürüm, Roketsan Missiles Inc. (Turkey)

To define signal and noise values; a passive athermal design (Li, H., Shen, M. 2008. An optically passive athermal infrared optical system. Proc. SPIE Vol 706010.) is used as a basis. Transmission values are calculated accordingly for 10 anti-reflect coated surfaces (dome+4 optics). Range between source object and the optical system is chosen to be 2000 meters and atmospheric attenuation calculated according to NATO literature (STANAG 4347). Optical performance criteria are calculated using computer assisted optical design programs (zemax and code5). Encircled energy values within the areas defined by pixel pitch are extracted from these design outputs to determine the contribution of image to signal as well as to noise. To further define noise, f/# contribution of the design is also considered.

To evaluate the contribution of quality of the optical design to the signal to noise ratio, different alterations of the original optical design are analyzed accordingly.

8840-9, Session 3

Computational methods to compute wavefront error due to aero-optic effects

Victor L. Genberg, Sigmadyne, Inc. (United States); Mark Bury, Keith B. Doyle, Thomas B. Sebastian, MIT Lincoln Lab. (United States)

Aero-optic effects can have deleterious effects on high performance airborne optical sensors that must view through turbulent flow fields created by the aerodynamic effects of windows and domes. Evaluating aero-optic effects early in the program during the design stages allows mitigation strategies and optical system design trades to be performed to optimize system performance. This necessitates a computationally efficient means to evaluate the impact of aero-optic effects such that the resulting dynamic pointing errors and wavefront distortions due to the spatially and temporally varying flow field can be minimized or corrected. To this end, an aero-optic analysis capability was developed within the commercial software SigFit that couples CFD results with optical design tools. SigFit reads the CFD generated density profile using the CGNS file format. OPD maps are then created by converting the three-dimensional density field into a index of refraction field and then integrating along specified paths to compute OPD errors across the optical field. The OPD maps may be evaluated directly against system requirements or imported into commercial optical design software including Zemax® and Code V® for a more detailed assessment of the impact on optical performance from which design trades may be performed.

8840-10, Session 3

Optical design including characteristics of manufactured nanostructures

Christoph A. Wächter, Martin Müller, Erik Förster, Maria Oliva, Dirk Michaelis, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany)

Micro- and nanostructures enable specific optical functionalities which rely on diffractive effects or effective medium features, depending on feature size and wavelength. Any intended functionality of the nanostructure is transferred somehow to its geometric details which can be reasonably straight forward or may require sophisticated numerical modeling when e.g. gratings in the resonance domain are required. Nevertheless, manufactured micro- and nanostructures will deviate from the ideal structure in shape, and material properties might be affected as well. This influences the performance of the optical system wherein these structures will be used. To include such fabrication effects and related tolerances in the system design measured characteristics are most suitable. To this end we use several goniometers where reflection and transmission properties of the artificial structures can be measured as function of input and output angles, wavelength, polarization, and lateral position. Since nanostructures in almost any case are fabricated on planar substrates, the measured characteristics then can be attributed to a planar optical element or surface. The corresponding model of that element which is to be incorporated in a ray-trace engine can be quite simple if diffraction efficiency in a single intended order is considered. Multiple diffraction orders and stray-light effects are required for in depth performance predictions of an optical system including a grating, which presupposes more extensive measurements and a more complex element model, consequently. Implementations relying on several types of nanostructured elements, including arrays of metallic nanoparticles and a metamaterial with asymmetric transmission [1] will be presented.

[1] C. Menzel et al., Phys. Rev. Lett. 104, 253902(2010)

8840-11, Session 4

Analysis of thermally-loaded transmissive optical elements

Gregory J. Michels, Victor L. Genberg, Sigmadyne, Inc. (United States)

The performance metrics of many optical systems are affected by temperature changes in the system through different physical phenomena. Temperature disturbances cause changes in the refractive properties of transmissive optics. Complex distributions of refractive indices that relate to the thermal profile, the thermo-optic refractive index profile, within the optical media can be predicted by the finite element method. One current technique for representing such refractive index profiles is through the generation of OPD maps by integration along integration paths. While computationally efficient, this method has limitations in its ability to represent the effect of the index changes for rays associated with multiple field points and multiple wavelengths. A more complete representation of the thermo-optic refractive index profile may be passed to the optical analysis software through the use of a user defined gradient index material. The interface consists of a dynamic link library (DLL) which supplies indices of refraction to a user defined gradient index lens as ray tracing calculations are being performed. The DLL obtains its refractive index description from a database derived from the thermal analysis of the optics. This process allows optical analysis software to perform accurate ray tracing for an arbitrary refractive index profile induced by changes in temperature. This paper is an update to this work already started in SPIE conference proceedings paper 8127-19.

8840-12, Session 4

STOP analysis modeling and the cielo solution platform

Mike Chainyk, Eric J. Cady, Daniel B. Klein, Gregory J. Moore, Stuart Shaklan, Luis Marchen, Marie Levine-West, Jet Propulsion Lab. (United States)

The Cielo software platform provides a solution capability for addressing high fidelity tightly coupled thermal, structural and optical (STOP) system design and performance modeling. The tenor of the approach lies in creation of a single instruction file that is, of itself, archival in its description of the finite element analogue to the true geometry through element topology, material property and optical surface specifications. Environmental characterization requires that we include the complete set of static as well as dynamic physical parameters that define the loads, boundary conditions and constraints across all three disciplines. Generally, the cascading effects (bucket brigade) are resolved automatically in a single analysis submittal as Cielo computes temperature, strain, displacement, rigid body optical surface motions and local deformation optical aberrations. Various optical metrics can be resolved with a simple call from within Cielo to either commercial or customized routines that post-process quantities such as WFE, beam walk and contrast.

The activity being described here will focus on the methodology for creating the single multidisciplinary model of interest and complete specification of the problem. Commercial modeling software will be discussed with respect to their capacity for creating the input constructs

upon which Cielo is driven. Given the breath of the Cielo solution, no commercial modeling package provides complete input descriptor coverage and we discuss efficient procedures for stop gap resolution. A number of intermediate solution metrics will be described with respect to measuring solution quality and the general problem flow and engineering principles employed will be examined. An end to end integrated physics model will provide the basis for a Cielo model building exercise and solution demonstration.

8840-13, Session 4

Coupling commercial software for STOP analysis at MIT Lincoln Laboratory

Gerhard P. Stoeckel, Keith B. Doyle, MIT Lincoln Lab. (United States)

Integrated optomechanical modeling provides critical insights into the interdisciplinary behavior and dynamics of high performance optical systems operating in ground, air, and space environments. Integrated models serve as predictive test beds capturing complex environmental conditions and concurrent disturbances yielding deterministic performance predictions at any point in time. MIT Lincoln Laboratory is developing custom software comprising an enterprise framework for use during the design and testing stages of hardware programs that couples existing commercial thermal (ThermalDesktop), structural (Nastran), optical (Zemax), and control (Matlab) software tools to inform architecture and system design decisions. Initial efforts have focused on development of a feature-rich software package designed to simplify STOP (structural-thermal-optical performance) analysis without sacrificing functionality or flexibility. This paper discusses the design of a framework and user interface for simple setup, execution and validation of STOP analyses on arbitrarily complex optical systems.

8840-15, Session 4

Multiphysics modeling and uncertainty quantification for an active composite reflector

Lee D. Peterson, S. Case Bradford, John E. Schiermeier, Gregory S. Agnes, Scott A. Basinger, Jet Propulsion Lab. (United States)

A multiphysics, high resolution simulation of an actively controlled, composite reflector panel is developed to extrapolate from ground test results to flight performance. The subject test article has previously demonstrated sub-micron corrected shape in a controlled laboratory thermal load. This paper develops a model of the on-orbit performance of the panel under realistic thermal loads, with an active heater control system, and performs an uncertainty quantification of the predicted response. The primary contribution of this paper is the first reported application of the Sandia developed Sierra mechanics simulation tools to a spacecraft multiphysics simulation of a closed-loop system. The simulation was developed so as to have sufficient resolution to capture the residual panel shape error that remains after the thermal and mechanical control loops are closed. As such, the thermal mesh is converged to milli-kelvin scale resolution, and the structural mesh is converged to submicron scale resolution, both over millimeters of spatial wavelengths. An uncertainty quantification analysis was performed to assess the predicted tolerance in the closed-loop wavefront error. Key tools used for the uncertainty quantification are also described.

8840-16, Session 4

The diffraction grating in the Ivory optomechanical modeling tools

Alson E. Hatheway, Alson E. Hatheway Inc. (United States)

In imaging spectrometers it is important that both the image of the far-field object and the image of the spectra be stable on the detector plane. Lenses and mirrors contribute to the motions of these images but motions of the diffraction grating also have their own influences on these image motions. This paper develops the vector equations for the images (spectra) of the diffraction grating and derives their optomechanical influence coefficients from them. The Ivory Optomechanical Modeling Tools integrates the diffraction grating into the larger optical imaging system and formats the whole system?s influence coefficients suitably for both spreadsheet and finite element analysis methods. Their application is illustrated in an example of a spectrometer exposed to both static and dynamic disturbances.

A method for measuring laser incident direction with non-imaging mode and resolution analysis

Bing Li, Yuejin Zhao, Xiaohu Guo, Jingshui Zhang, Lingqin Kong, Beijing Institute of Technology (China)

One of the most crucial techniques of laser warning system is to acquire the direction information from the laser threat. According to the low resolution of laser warning system with imaging mode, a new method for measuring laser incident direction which possessed higher resolution was proposed. This novel method was based on cylindrical lens group and linear IRFPA, and the laser incident direction was achieved by offset of line spot. It not only deduced the direction formulas, but also analyzed the resolution of measuring laser incident direction in detail. The simulation result shows that the FOV of this new kind of laser warning system could achieve ±16°; the azimuth resolution is up to 0.52° and pitch resolution is up to 0.017°; the resolution increases with incident angle. In addition, an experiment with visible light, single cylindrical Len, linear array CCD was done to verify this method and its advantage on resolution. The analysis of laser incident orientation resolution is significant to select suitable parameter of detector and demonstrate orientation resolution of system.

8840-19, Session 5

Feasibility of near-infrared markers for guiding surgical robots

Azad Shademan, Matthieu F. Dumont, Simon Leonard, Axel Krieger, Peter C. W. Kim M.D., Children’s National Medical Ctr. (United States)

Automating surgery using robots requires robust visual tracking. The surgical field has often poor light conditions where several organs have similar visual appearances. In addition, the field of view might be occluded by blood or tissue. In this paper, the feasibility of near-infrared (NIR) fluorescent imaging for vision-based robot control is studied. The NIR region of the spectrum has several useful properties including deeper depth penetration. We study the optical properties of a clinically-approved NIR fluorescent dye, indocyanine green (ICG), with different concentrations and quantify image positioning error of ICG marker when occluded by artificial tissue.

8840-20, Session 5

Integrated analysis of FORMOSAT-5 remote sensing instrument in space

Chia-Ray Chen, Ching-Wei Chen, Mei-Yi Yang, Cheng-En Ho, National Space Organization (Taiwan); Shenq-Tsong Chang, Ting-Ming Huang, Instrument Technology Research Ctr. (Taiwan)

FORMOSAT-5 is the first space program fully developed by National Space Organization (NSPO). The Remote Sensing Instrument (RSI) will provide spatial resolution of 2 meters in panchromatic band and 4 meters in multi-spectral bands. The optical system is composed of two reflective aspheric mirrors and spherical corrector lens set. CFRP structure is used for the optomechanical system to reduce mass. Although the telescope system can be well aligned on ground, the space thermal environment can result in thermal distortion of telescope system and impact the final image quality. Flight predictions of FORMOSAT-5 RSI were done to get the quantitative thermal distortion of mirrors and structural system. The system optical performance, i.e. MTF, was also derived by the optical model with the input from thermal distortion results, i.e. Zernike polynomials. RSI performance in space is location-dependent. Detailed analysis results and discussions will be revealed in this paper.

8840-21, Session 5

Measurement in the fringes: Experimental mechanics approaches for model verification of precision structures

Gregory S. Agnes, Samuel Case Bradford, Lee D. Peterson, Jet Propulsion Lab. (United States)

No Abstract Available

Sunday - Tuesday 25–27 August 2013

Part of Proceedings of SPIE Vol. 8841 Current Developments in Lens Design and Optical Engineering XIV

8841-1, Session 1

Simultaneous color-mixing and collimation within LED package *(Invited Paper)*

Ivan Moreno, Jose Carlos Basilio, Univ. Autónoma de Zacatecas (Mexico)

A compact encapsulating lens is proposed and analyzed, which simultaneously collimates and mixes the tunable light from red, green and blue (RGB) light-emitting diode (LED) chips. Colored LED chips are embedded within a spherical lens, and a section of the sphere that surrounds chips is mirrored with a diffuse reflector. Color light is mixed by multiple total internal reflections (TIRs), the scattering mirror breaks TIR, and light escapes only in a narrow beam in the forward direction. The color uniformity, the beam pattern, and efficiency are analyzed by Monte Carlo ray tracing calculations.

8841-2, Session 1

Optical design for anti-glare LED projection based on a confocal double-reflector

Yi-Chien Lo, Xuan Hao Lee, Chih-Chi Tsai, Wei-Ting Chien, Ching-Cherng Sun, National Central Univ. (Taiwan)

In this paper, we present a new optical design of a confocal double-reflector for white LED light. It can perform uniform illumination with a specific projection angle. Furthermore, our design can prevents direct view of the LED, and the measured veiling luminance is much lower than that in general LED-based projection lamps.

8841-3, Session 1

Optical design of the projection lamp for large area based on white LEDs

Jhih-You Cai, Yi-Chien Lo, Jheng-Yu Cai, Ching-Cherng Sun, National Central Univ. (Taiwan)

In our research, we designed a projection lamp for large area based on white-light LEDs. In general, the projection lamp of the outdoor lighting was set up in the margin of the target area. However, most of the projection lamps of the outdoor lighting were distortion light pattern instead of specific light pattern, e.g., rectangular light pattern. This means that the specific light pattern was illuminated in the target area and the energy was saved. In design of the projection lamp, we first built a precise optical model for the high-power LED produced by CREE in mid-field verification to guarantee the accuracy of our simulation. After creating the precise light source model, we designed the process of the secondary optics of projection lamp. Since the projection lamp had tilted angle and set up in the margin of illumination area, to perform uniform and rectangular light pattern was not easy. When the angle of the lamp did not tilt, the shape of the light pattern was trapezoid. When the lamp had tilted angle, the shape of the light pattern became rectangle. This concept was correcting the shape of light pattern and illuminating for large area, when the projection lamp had tilted angle and set up in the margin of illumination area.

8841-4, Session 1

Hybrid solid state illuminator

Junejei Huang, YuChang Wang, Delta Electronics, Inc. (Taiwan)

A laser-phosphor projector uses laser to pump phosphors and applies the excited lights as projecting light source for full color display. Conventionally, red color in laser-phosphor projector is not sufficient and size of the laser-phosphor light module is too large to fit into the existing optical engine that originally designed for the UHP lamp. To overcome the difficulties of the conventional laser-phosphor illuminator, a hybrid solid state illuminator is proposed.

In this hybrid solid state light source, blue and red lights from laser diodes and yellow light from YAG phosphor are combined and formed into a compact lamp module. 100 sets of laser diodes (with collimating lens in front of each) are concentrated and aligned by stripes of mirrors and formed into a laser bank. The assembly technique, coupling efficiency, spot size and beam quality of the laser bank are discussed.

Laser light of 445nm is guided and converged into the phosphor disk. For the phosphor, the material choice, its binder and Al disk that supporting and ventilating the phosphor are discussed.

Yellow spectrum and residual blue light are generated after the pumping of the 445nm blue laser light. The generated light is further combined with laser lights of 462nm and 639nm by using a structure comprising TIR prism and narrow band reflection filter. A wide color gamut (Rec. 709) and high efficiency are got. Using this hybrid solid state lamp module in a 3-chip projector having 0.95" DMD, an output of 10K lumen to the screen will be demonstrated.

8841-5, Session 2

Offer more different wavelength bands for plant cultivation using a polygonal beam splitter

Yi-Shiuan Chen, Jong-Woei A. Whang, National Taiwan Univ. of Science and Technology (Taiwan)

More and more developed countries in the world advocate the importance of natural and sustainable green life. As the residents of the global village, we need to have the consciousness of environmental protection. The Shanghai World Expo 2010 Exhibition and the 2010 Taipei International Flora Exposition both have demonstrated a lot of landscape plants and green buildings. The United States, China and Taiwan have been concentrated on the development of plant cultivation which needs proper light source for high economic crops and flowers. Therefore, in accordance with the characteristics of plants we supply the lighting illuminations in different wavelength band for plants growth.

In our research, we design a polygonal beam splitter. Usually beam splitters separate the primary colors of light into red, blue and green lights, but this polygonal beam splitter split sunlight by using the coating method which the outer and the inner of the dichroic mirror are coated with different optical films. The polygonal beam splitter can separate sunlight into more different light wavelengths with delicate color temperature, offering more different wavelength bands for plant cultivation.

8841-6, Session 2

Radiance limits of ceramic phosphors under high excitation fluxes

Alan Lenef, John Kelso, Yi Zheng, Maxim Tchoul, OSRAM SYLVANIA Inc. (United States)

Thermodynamic arguments suggest that the radiance of a luminescent spot can exceed the radiance of its shorter wavelength incoming pump source. In practice, however, thermal quenching and optical saturation (non-thermal) limit the maximum attainable radiance. We present experimental data from static laser-pumped Ce:YAG and Ce:GdYAG ceramics in which both of these limits have been investigated. Optical pumping intensities exceeding 100W/mm2 have been shown to produce only modest efficiency depreciation due to optical saturation at low overall pump powers because of the short Ce3+ lifetime. However, when pump powers reach a few watts, heat-transfer bottlenecks within the ceramic and interfaces severely limit maximum pump intensities. We find that surface temperatures of laser-pumped ceramics can easily exceed 150 °C, causing considerable thermal-quenching losses. We also find that in some cases, the loss of quantum efficiency with increasing temperature can cause a thermal run-away effect, resulting in a rapid loss in converted light and sample over-heating. While one can still obtain radiant emittances on the order of several W/mm2, these temperature quenching effects ultimately limit converted light radiance. Finally, we use diffusion-approximation radiation transport models to simulate some of these nonlinear heating effects in high-scattering ceramics and compare with experimental data.

8841-7, Session 2

Beam shaping for high-uniformity illumination based on power chip LEDs

Rodolfo Garcia-Camacho, Jhe-Syuan Lin, Soo-Fan Phua, Yi-Chien Lo, Ching-Cherng Sun, Chao-Wen Liang, National Central Univ. (Taiwan)

Uniform illumination is a prerequisite in many optical systems. However, light sources usually don't produce enough uniformity. Therefore, some modification of the irradiance pattern produced by the light source is needed. In this paper, we design an optical system with fly's eye lens to redistribute light from an LED source and obtain high uniformity illumination and efficiency. Our work also includes designing a collimating system and doing a complete analysis. Finally, we demonstrate our design by testing a real optical system

8841-8, Session 2

Application of heterogeneous microlenses for solid state lighting

Weiting Shih, National Taiwan Univ. (Taiwan)

In recent years, LED was applied to lighting in bulk, mostly used in territory of backlight lighting. Therefore, our research would focus on backlight lighting. In this paper, two methods were adopted to obtain freeform surface with axial symmetry and non-axial symmetry. Then by the freeform lens constructed by us, we would make the light field intensity more uniform. In the end of the thesis, we would utilize MLA to approximate the shape of the freeform lens, and adjust the curvature radius and size of the micro lens, and the arrangement way of the micro lens by the simulation results. Through repeated trials, we would achieve the uniformity effect of LED's light.

8841-9, Session 3

Analysis of the correction properties and capabilities of optical systems

Sergey N. Bezdidko, Open Joint-Stock Co. (Russian Federation); Yuri A. Roy, Open Joint-Stock Co. (Russian Federation)

The unique properties of orthogonal aberrations provide an opportunity to form a system of criteria and methodology for evaluating correction properties and capabilities of optical systems based on the use of the expansion of the wave aberration in generalized Zernike polynomials in the three-dimensional domain of field - pupil $0 \leq r \leq 1$, $0 \leq \rho \leq 1$, $0 \leq \varphi \leq 2\pi$ and the separation of the contributions of aberrations of lower and higher orders in the image deterioration.

This report describes practical application of proposed approaches in analysis and optimization and examples of calculation of the specific optical systems.

8841-10, Session 3

Orthogonal aberrations and their role in lens design

Sergey N. Bezdidko, Open Joint-Stock Co. (Russian Federation)

The author introduces a complete set of polynomials that are orthogonal to the three-dimensional region (generalized Zernike polynomials). These polynomials make it possible to obtain orthogonal expansion of the wave aberration in the three-dimensional domain of field - pupil $0 \leq r \leq 1$, $0 \leq \rho \leq 1$, $0 \leq \varphi \leq 2\pi$. These permit to determine the orthogonal system of individual aberrations and introduce a classification of individual aberrations depending on the degree of field and pupil variables r ρ, φ. The author shows that orthogonal aberrations have a number of unique properties which makes it possible to build new effective approaches and techniques to the design of optical systems.

The developed approach describing the aberration properties of optical systems by means of orthogonal aberrations and its use in the construction of new methods and techniques to the design of optical systems form a new section of lens design, namely, "The theory of orthogonal aberrations and its applications in the design of optical systems."

8841-11, Session 3

Polarization fields for understanding polarization aberrations in imaging systems *(Invited Paper)*

José Sasián, College of Optical Sciences, The Univ. of Arizona (United States)

Polarization effects in imaging systems can be significant and, therefore, understanding the subject of polarization aberrations is important in the design of optical instruments. However, and despite a few works on the subject of polarization aberrations, it is still not clear how best to approach learning of this subject, and thus acquire a solid foundation.

This talk provides a foundation to easily understand polarization aberrations in optical imaging systems by developing the concept of polarization fields. A useful set of fields is constructed, notably from the aberration function of plane symmetric systems, and used to get insight. We also discuss polarization aberration coefficients and provide some insightful examples. The audience will get a useful primer on the topic.

8841-12, Session 3

Design of fisheye lens with slope-constrained Forbes aspheres

Qingfeng Wang, Dewen Cheng, Yongtian Wang, Beijing Institute of Technology (China)

1. Introduction

In the information age nowadays, fisheye lenses are more and more widely used in navigation, surveillance, machine vision, etc. [1-4]. Aspheric surfaces are often used in their designs in order to meet the requirements on image quality and system size and weight. A new method of specifying aspheric surfaces was proposed by G. Forbes [5], which has significant advantages in the design of rotational symmetry systems [6-7]. Now Forbes asphere has been integrated into the optical design software CODE V [8].

2. Technical specifications of the fisheye lenses and design considerations

Because of the very large field angle, a fisheye lens for automobile navigation must have a large numerical aperture in order to provide sufficient illumination at the edge of the image surface. At the same time, strict restrictions on the lens element number and system overall length greatly increases the difficulty of the design task.

The main specifications for our design are as follows: diagonal size of the detector = 1/4"; full field angle ≥ 180°; F/number ≤ 2.5; system length ≤ 30mm; full field relative illumination ≥ 40%; Number of lens elements ≤ 6.

The material of the first lens element has to be glass in order to sustain the sometimes harsh environmental conditions outside the vehicle. The materials of the lens elements with aspheric surfaces need to be plastic (APEL) so that these elements can be molded in mass production to reduce the cost. For these molded lens elements, both surfaces can be aspheric since there is not much difference in cost. Forbes asphere is used to describe their surface shapes, so that the surface slopes can be effectively constrained during the optimization to be suitable for molding.

3. Design results and analysis

Two design results are given. Figure 1 and figure 2 show their system layouts, MTF curves and curves of field curvature and distortion. The first design gives a full field angle of 190°. It is very compact, with an overall length of only 14.3mm and four lens elements, including two aspheric elements. The MTF values for almost all the sampled fields are above 0.4 at the Nyquist frequency of 45lp/mm, the f-θ distortion is less than 10%, and the full field relative illumination is greater than 40%.

The second design provides an even larger field angle of 210°. Six lens elements are used in this design, again with two aspheric elements. The overall length of this design is 30mm, which is still more compact than most common fisheye lenses. The MTF values remain greater than 0.4 except for a couple of sampled fields at the corner of the image surface. The f-θ distortion is further reduced to 2%, and the full field relative illumination is again greater than 0.4.

4. Conclusions

In this Paper, two fisheye lenses are designed with super field angle 190º and 230º respectively, the results of the designs show that Forbes aspheres can not only improve the image quality but also decrease the difficulties of the fabrication and testing of aspheric surface.

8841-13, Session 3

Analytic formulas of the aspheric terms for Convex-Plano and Plano-Convex aspheric lenses

Maximino M. Avendaño-Alejo, Univ. Nacional Autónoma de México (Mexico)

The aspheric lens can help simplify optical system design by minimizing the number of elements required and yields sharper images than conventional lenses. In this work we provide analytic formulas for fews aspheric terms either Plano-Convex or Convex-Plano aspheric lenses. These formulas are obtained considering a expansion in Taylor's series from exact caustic equation produced by aspheric lenses. A comparison between our aspherical terms obtained through these formulas and the aspheric terms provided by another methods of design are presented, showing a well agreement in order to reduce the spherical aberration.

8841-14, Session 4

Multi-core and GPU accelerated simulation of a radial “star” target imaged with equivalent t-number circular and Gaussian pupils

Alan W. Greynolds, Ruda-Cardinal, Inc. (United States)

Results from the GelOE optical engineering software are presented for the through-focus, monochromatic coherent and polychromatic incoherent imaging of a radial “star” target for equivalent t-number circular and Gaussian pupils. The FFT-based simulations are carried out using OpenMP on a multi-core desktop computer, with and without the aid of a many-core NVIDIA GPU accessing its cuFFT library. It is found that a custom FFT optimized for the 12-core host has similar performance to a simply implemented 256-core GPU FFT. A more sophisticated 448-core GPU version (tuned to reduce overhead) is 20 to 28 times faster than a basic FFT implementation running on one CPU core.

8841-15, Session 4

Man versus machine: a lens design challenge *(Invited Paper)*

Donald C. Dilworth, Optical Systems Design, Inc. (United States); David R. Shafer, David Shafer Optical Design (United States)

After a generation of writing and improving lens design software, it is time to assess where we are. Specifically, can a modern program compete, or surpass, the best human designers? Here we describe a friendly contest between two leaders in the field.

8841-16, Session 4

Design of wearable binoculars with on-demand zoom

Robert R. Boye, Ronald S. Goeke, Jeffrey P. Hunt, Aaron M. Ison, Bradley H. Jared, Jamin R. Pillars, Michael P. Saavedra, William C. Sweatt, W. Graham Yelton, Edward G. Winrow, Steven L. Wolfley, Sandia National Labs. (United States)

Sandia has developed an optical design for wearable binoculars utilizing freeform surfaces and switchable mirrors. The goals of the effort included a design lightweight enough to be worn by the user while providing a useful field of view and magnification as well as non-mechanical switching between normal and zoomed vision. Sandia's approach is a four mirror, off-axis system taking advantage of the weight savings and chromatic performance of a reflective system. The system incorporates an electrochromic mirror on the final surface before the eye allowing the user to switch between viewing modes. Results from a prototype of a monocular version of an 6.6x design will be presented. The individual mirrors, including three off-axis aspheres and one true freeform, were fabricated using a diamond-turning based process. A slow-slide servo process was used for the freeform element. Surface roughness and form measurement of the freeform mirror will be presented as well as the expected impact on performance. The alignment and assembly procedure will be reviewed as well as the measured optical performance of the prototype. In parallel to the optical design work, development of an electrochromic mirror has provided a working device with faster switching than current state of the art. Switchable absorbers have been demonstrated with switching times less than 0.5 seconds. The deposition process and characterization of these devices will be presented. Finally, details of an updated optical design with additional freeform surfaces will be presented as well as plans for integrating the electrochromic mirror into the system.

8841-17, Session 4

Optical design and optimization of zoom optics with intermediate image

Yi-Chin Fang, National Kaohsiung First Univ. of Science and Technology (Taiwan)

An optical design of 9X optical miniature zoom lens with intermediate image method has been presented in this research. Intermediate image is applied in order to minimize of front diameter of zoom optics. Moreover, a compensative optimization method with assistance of Genetic Algorism is introduced in this research with a new concept of DLGS,(Discrete

Lens Groups Shifts) which not only solve the complicated problem of intermediate image itself but also improve the performance of optics. Genetic algorithms (GA) written in CODE V plays the role at finding out the appropriate parameters such as curvatures, thicknesses, glass materials and etc. Besides, one table with great lens groups shifts by GA would be created to move the lens groups on the optimal positions of different zooms. As a result, the DLGS optimization method associated with the GA optimization eliminate the zoom lens diameter averagely 25% better than traditional ones.

8841-18, Session 4

A 3D photographic capsule endoscope system with full field of view

Wei-De Jeng, Yi-Chinn Kung, Kuan-Heng Tao, Ou-Yang Mang, National Chiao Tung Univ. (Taiwan)

Current capsule endoscope uses one camera to capture the surface image in the intestine. It can only observe the abnormal point, but can not know the exact information of this abnormal point. Using two cameras can generate 3D images, but the visual plane changes while capsule endoscope rotates. It causes that two cameras can't capture the images information completely. To solve this question, this research provides a new kind of capsule endoscope to capture 3D images, which is "A 3D photographic capsule endoscope system ". The system uses three cameras to capture images in real time. The advantage is increasing the viewing range up to 2.99 times respect to the two camera system. The system can accompany 3D monitor provides the exact information of symptom points, helping doctors diagnose the disease.

8841-19, Session 5

Double micro-prism array design for reducing dispersion on prism-based stereo camera system

Wen-Shing Sun, Pu-Yi Chu, National Central Univ. (Taiwan)

In this study, we used the two micro-prism array to reduce the chromatic aberration of the system in the stereo photography. First of all, we select two partial dispersion differences smallest difference with the Abbe number of plastics as the material of the micro-prism array, we think this can eliminate the primary chromatic aberration, while secondary chromatic aberration will be smaller. In order to divide the image into two, we determine the total deviation angle, and then find the vertex angle combination which makes the primary chromatic aberration is close to zero. Finally, we use optical software to compare the results of single and double micro-prism array.

8841-20, Session 5

Micro-optical elements for optical wireless applications

Xian Jin, Daniel Guerrero, Richard Klukas, Jonathan F. Holzman, UBC Okanagan (Canada)

Optical wireless technology is an attractive solution for indoor wireless networks seeking high-bandwidth and mobility. Developments have emerged for improved signal reception in optical wireless communication (OWC) and optical wireless location (OWL) applications, and imaging receivers are often employed in these systems. Imaging receivers use lenses and arrayed photodetectors to image an overhead optical transmitter grid and isolate the individual optical channels. The contemporary challenges for these implementations relate to the desire for a wide field-of-view (FOV) with an integrated architecture. The wide FOV can establish links with multiple optical wireless channels, but this capability is difficult to integrate in micro-optical architectures.

In this work, customized microlenses are introduced for use in OWC and OWL applications. The microlenses are fabricated with especially high contact angles to establish large numerical apertures (NAs) and wide FOVs. An electro-dispensing technique is used to create the microlenses. Each microlens is formed from dispensed UV-curable polymer with pressure-control defining the microlens volume. At the same time, a tunable voltage is applied to the metal dispensing tip to fine-tune the microlens profile by way of the electrowetting effect. When the ideal microlens profile is achieved, UV-curing is applied. This technique is used to create microlenses with diameters down to 200 μm and NAs up to 0.6. The microlenses are integrated above a CMOS imaging sensor for operation with especially wide FOVs. The prospects for these new micro-optical elements are discussed for emerging OWC and OWL applications.

8841-22, Session 5

Optical architecture of the new generation Infrared Atmospheric Sounder Interferometer (IASI-NG)

Clement Luitot, Ctr. National d'Études Spatiales (France)

IASI (Infrared Atmospheric Sounder Interferometer) is a Fourier Transform Spectrometer (FTS) working in the 3,6μm – 15,5μm range, dedicated to Numerical Weather Prediction, atmospheric chemistry and climate monitoring. The second flight model (2 out of 3) is now in orbit and operational, as a payload of the MetOp-B satellite.

A new generation of instrument (IASI-NG) to continue the IASI mission with increased performances is currently investigated by the French Space Agency (CNES). The performance objective is mainly a spectral resolution and a radiometric noise divided by two compared with the IASI ones. Many different concepts of FTS were studied to try to fulfill these challenging requirements.

This paper presents the different envisaged optical architecture and associated trade off.

The major issue of the concept is to manage the so-called self-apodization of the interferogram and the associated degradation of the spectral resolution induced by the wider Field of View and the longer Optical Path Difference. Increasing these two quantities have very constraining consequences on the optical architecture. Another critical point is the control of strayligth which is quite severe and which has been taken into account early in the optical design. To assess the performances of the interferometer, different optical models were built combining analytical approach with ray tracing technics. We will describe the impacts of the demanding spectral requirements on the optical components and our analyses, based on these models will be presented.

8841-23, Session 5

A three-channel miniaturized optical system for multi-resolution imaging

Gebirie Yizengaw Belay, Heidi Ottevaere, Youri Meuret, Hugo Thienpont, Vrije Univ. Brussel (Belgium)

Multi-channel imaging systems are inspired by natural compound eyes of insects. Such systems have many channels that share the total Field-Of-View (FOV). In this work, our aim was to manipulate the different channels such that different imaging properties (focal length, angular resolution) are obtained for each channel. This adds multi-resolution functionality to the imaging system. We have designed a three-channel imaging system where the first channel has the highest angular resolution (0.0096 degree) and narrowest FOV (7 degree) and the third channel has the smallest angular resolution (0.078 degree) and widest FOV (80 degree). The second channel has intermediate properties. Each channel consists of 4 aspherical lens surfaces and an absorbing baffle that avoids crosstalk with the neighbouring channels. The aspherical lens surfaces have been fabricated in PMMA by ultra-precision diamond turning and the baffles by metal additive manufacturing. The integrated and stacked imaging system comprises two lens plates featuring the 4 lens surfaces, an absorbing plate with baffles, all connected by thin capillary columns running through alignment holes, and a commercial CMOS sensor. The CMOS sensor simultaneously captures images of different resolution at its different segments. This creates a possibility of implementing different image processing algorithms on the different image sensor segments. The MTF and FOV of the channels were calculated from the captured images. The obtained results show that there is a good agreement between the performances of the simulation and the experiment and this paves the way towards miniaturized smart imaging systems.

8841-24, Session 6

Internal structure of bokeh image in camera lenses with aspheric surfaces

Viktor P. Sivokon, Mike Thorpe, Raytheon ELCAN Optical Technologies (Canada)

In photography, bokeh is the characteristic of the image of out-of-focus points of light as rendered by a particular lens and is sometimes treated as a lens performance metric. We present theoretical, numerical and experimental analysis of the internal structure of bokeh images as seen in shots taken with camera lenses which incorporate aspheric surfaces. We show that detailed structure of bokeh closely reflects characteristics of the manufacturing process for aspheric surfaces, and is due to light diffraction on the phase grating associated with the surface. We derive a simple formula for estimating intensity modulation ratio of the resulting bokeh based on the out-of-focus distance, amplitude and frequency of surface profile undulations. Numerical simulations of bokeh formation were carried out for two imaging systems: a simplified parabolic mirror and a photographic lens. The simplicity of the parabolic imager allows for direct comparison between theory and simulation. We find that modulation depth in the bokeh structure calculated by light propagation based simulation agrees with theory when the modulation depth is < 30%. Bokeh is found to be highly sensitive to the presence of residual aspheric surface structures. Even when peak to valley departures of these structures are reduced to such low levels that that there is negligible impact on the modulation transfer function, structure and modulation depth in the bokeh may still be quite pronounced. Finally, bokeh obtained for a built lens with known residual aspheric surface structure is shown to be in agreement with a numerical simulation of the imagery.

8841-25, Session 6

Some methods of determination of limit potential image quality of optical systems of various complexities using database of optical systems

Sergey N. Bezdidko, Open Joint-Stock Co. (Russian Federation)

In the report some methods of processing of the information contained in a database of the optical systems are offered with the purpose of extraction of the knowledge, the experience and the intuition of the designers, coded in the database.

Statistical analysis of external characteristics (angular field of view, aperture, focal length), the structural characteristics (number of lenses, etc.) and achieved aberration correction of optical systems has revealed important relationships between characteristics. This allows us to develop methods of analysis of the maximum possible image quality of optical systems of various complexities.

8841-26, Session 6

Stray light analysis of active laser ranging optical system

Jinsuk Hong, Samsung Thales Co., Ltd. (Korea, Republic of)

We performed the stray light analysis of the Active Laser ranging system. To analyze the system, optical components and mechanical components were imported to ASAP software. Actual measurement data of the coating and ASAP's inner library of scatter properties were applied to the optical components. Mechanical components were considered to be 100% absorbing media in this simulation to simulate the optical components effect only.

First, we check the backward reflection to the FPA array caused by the wedge scanner. Since the wedge scanner rotates in different speed, we selected specific position of each scanner and performed the analysis. We can conclude that Scanner rotation position doesn't affect the performance of the FPA.

Then, we check the inner reflection caused by the optical components such as ghost effect. Ray tracing was performed in three fields, center, 0..7 and corner, and we found the Filter's ghost effect can be problem. To eliminate the ghost from the filter, we rotated the filter. We can confirm the Signal-to-Noise ratio were improved by simulation and examination.

8841-34, Session PMon

Parametric analysis of the effect of scatter upon the modulation transfer function

James E. Harvey, Richard N. Pfisterer, Scott Ellis, Photon Engineering LLC (United States)

The modulation transfer function (MTF) is widely used as the image quality criterion of choice for imaging applications where fine detail in extended images needs to be specified or evaluated. This is particularly true for imaging systems degraded by diffraction effects and geometrical aberrations. However, there seems to be a perception among many optical engineers that the MTF is not significantly degraded by scattered or stray light. This perception may be due to the fact that wide-angle scattered light does not visibly distort the fringes of a full-aperture test interferogram. In this paper we present a detailed parametric analysis of the effect of scattered light upon the MTF of an imaging system, and illustrate the results for three specific applications: (i) a short-wavelength extreme ultraviolet Newtonian telescope where scattering effects can dominate both diffraction effects and aberrations in the resulting image degradation, (ii) a visible Newtonian telescope with state-of-the-art optical surfaces which produce no significant effect upon the MTF, and (iii) a system made up of three diamond-turned off-axis aspheric mirrors where we use the predicted MTF to estimate whether post-polishing will be required to meet a specific image quality requirement. We also discuss how to calculate the MTF degradation due to stray light from bulk or particulate scatter provided either measured or assumed BSDF data is available.

8841-35, Session PMon

Innovative wide-field and fast Schmidt camera design

Sandrine Pascal, Sébastien Vivès, Observatoire Astronomique de Marseille-Provence (France); Robert Barkhouser, Johns Hopkins Univ. (United States)

It is commonly accepted that Schmidt cameras allow achieving fast F-ratio and large field of view. Developed from the 1930s, the classical Schmidt cameras are made of full-aperture lens corrector located at the center of curvature of a spherical mirror. The combination of these two elements produces a system free of the four primary aberrations (spherical, coma, astigmatism and distortion). Only the field curvature

remains but it can be compensated by the use of a field flattener (before the focal plane).

In the framework of the SuMIRe Prime Focus Spectrograph (PFS) being developed for the 8-m class SUBARU telescope, we are proposing an innovative Schmidt camera observing a large field-of-view (20 degrees in diameter) with a very fast beam (F/1). Basically, we introduced a catadioptric mirror (i.e. a meniscus with the reflection on its back surface, like a Mangin mirror), instead of the classical spherical mirror.

In this paper, we will describe in detail the proposed optical solution for SuMIRe/PFS and the performance achieved. We will also present a parametric analysis of our solution allowing outlining the advantages and limitations of our approach for other applications.

8841-36, Session PMon

Pyramid wavefront sensor for image quality evaluation of optical system

Dan Zhou, Zhendong Chen, Shanghai Astronomical Observatory (China)

When the pyramid wavefront sensor is used to evaluate the imaging quality, placed at the focal plane of the aberrated optical system e.g., a telescope, it splits the light into four beams. Four images of the pupil are created on the detector and the detection signals of the pyramid wavefront sensor are calculated with these four intensity patterns, providing information on the derivatives of the aberrated wavefront. Based on the theory of the pyramid wavefront sensor, we are going to develop simulation software and a wavefront detector which can be used to test the imaging quality of the telescope. In our system, the subpupil image intensity through the pyramid sensor is calculated to obtain the aberration of wavefront where the piston, tilt, defocus, spherical, coma, astigmatism and other high level aberrations are separately represented by Zernike polynomials. The imaging quality of the optical system is then evaluated by the subsequent wavefront reconstruction. The performance of our system is to be checked by comparing with the measurements carried out using Puntino wavefront instrument (the method of SH wavefront sensor). Within this framework, the measurement precision of pyramid sensor will be discussed as well through detailed experiments. In general, this project would be very helpful both in our understanding of the principle of the wavefront reconstruction and its future technical applications. So far, we have produced the pyramid and established the laboratory setup of the image quality detecting system based on this wavefront sensor. Preliminary results are obtained, in that we have obtained the intensity images of the four pupils. Additional work is needed to analyze the characteristics of the pyramid wavefront sensor.

8841-37, Session PMon

Freeform mirror polishing for compensation on non-symmetry system aberrations of remote sensing instrument

Ching-Hsiang Kuo, Zong-Ru Yu, Cheng-Fang Ho, Wei-Yao Hsu, Fong-Zhi Chen, Instrument Technology Research Ctr. (Taiwan)

Cassegrain optical systems are widely used in remote sensing instrument. Cassegrain telescope is composed of a primary mirror (M1), a secondary mirror (M2), and a set of correction lenses. The system aberrations of telescope could be corrected and balanced by M1 and M2. In the event of deformation of telescope assembly, the non-symmetry aberrations will be induced to the optical system and reduce the optical performance. The non-symmetry aberrations could be measured after completing of M1 and M2 assembly and alignment processes. We could compensate this identified error to M1 or M2 for improving the optical performance. The error compensation on M2 is efficient for polishing process due to the smaller aperture. In this study, we apply an exact aberration that was caused by deformation of mirror supporting and gravity on the designed aspheric surface of M2. The surface of M2 becomes freeform from aspheric. The polishing process combines the techniques of conventional lapping and CNC polishing. We apply the conventional spherical lapping process to quick remove the sub-surface damage (SSD) layer and to get the accurate radius of best fit sphere of aspheric surface with fine surface texture simultaneously. The polishing and metrology processes were performed by using Zeeko IRP1000 polisher and QED ASI stitching interferometer. A ?150 mm mirror with freeform surface was completed.

Using the toroidal and cylindrical lenses to project the RGB LEDs sources on the lens array with elliptic solid angle calculation for the DLP projector

Wen-Shing Sun, National Central Univ. (Taiwan)

We present an illuminated projection system design to improve the efficiency and uniformity. First, the light sources of RGB LEDs pass through the toroidal and cylindrical lenses to image on the lens array. For the image, the vertical and horizontal magnifications are different. The magnifications can match the rectangular size of lens array. We use the elliptical solid angle calculation and enhance the efficiency of the light source. Second, we use lens array to split the light shape and to form many light sources, and design an uniform illumination system for projector. Third, the light sources pass through the projector lens to the screen. We analysis the image quality for the projector lens, and compute the efficiency, uniformity, and CIE chromaticity coordinate on the screen.

Three dimensional point spread function of a high aperture optical system

Volodymyr N. Borovytsky, Viktoriia V. Chorna, Alex Solovei, National Technical Univ. of Ukraine (Ukraine)

The paper presents the mathematical technique for precise calculation of the three dimensional point spread function (3D PSF) of a high aperture optical system. The comparison analysis shows that many known techniques for calculation of the point spread functions are generally based on Fresnel or Fraunhofer approximations. It causes the sufficient inaccuracy when high aperture optical systems are investigated. The proposed technique is based on Huygens-Fresnel principle: spherical wave at an exit pupil is considered as a numerous set of elementary secondary light sources. These sources emit spherical coherent electro-magnetic waves. All these waves form a definite distribution of summarized complex amplitudes in three dimensional space near the focal point. This distribution of the complex amplitudes is used for calculation of the distribution of effective intensities which take into account the influence of inclined elementary wave fronts. The limitations of possible approximations of the 3D PSF are analyzed. The algorithms for fast calculations of 3D PSF are described and illustrated by the calculated cross-sections of 3D PSF of typical microscope objectives. The links 3D PSF with a three dimensional line spread function and a three dimensional edge response functions are studied. The techniques for comparison of the calculated and measured data about 3D PSF are discussed.

Enhancement effect of terahertz wave in split ring resonators

Qinglong Meng, Bing Zeng, Wenyi Shao, Bin Zhang, Sichuan Univ. (China)

Based on the theory of split ring resonators (SRRs) and the rigorous

theory of electromagnetic field, the spatial distributions of the electric field and electric energy density in split ring resonators with different structures such as square, circle and triangle have been analyzed. The variation of electric energy density with different terahertz (THz) frequencies has also been investigated. It can be shown from our numerical simulation results that the electric field enhancement effect occurs in the split ring resonators with square, circle and triangle structures and the electric field near the opening is obviously stronger than that in other regions, especially in the gap of the split ring resonators. The maximum of the electric energy density appears in the opening of the SRRs and the electric field is obviously stronger near the resonance frequency of the SRRs. The results obtained in this paper have important significance on the design of the split ring resonators and the function of resonant magnetic response of left hand materials (LHMs).

Multi-agent system in automatic light power balance in optical networks

Martin Slapak, CESNET z.s.p.o. (Czech Republic) and Czech Technical Univ. in Prague (Czech Republic); Miloslav Hula, CESNET z.s.p.o. (Czech Republic)

An automated power balancing was performed on testbed with two amplifiers, two 75 km long fibre spans and one attenuation element. The parameters of link are measured by modular remotely controlled device FTB500 with Pocket Blazed FTB8510G module which puts 10Gbit traffic through link.

Balancing software was designed as multi-agent system with three types of agents. The first type is amplifier controller, which comunicates with assigned amplifier. The core type of an agent is „balancer“ which performs actions according to proposed balancing algorithm. The last one handles GUI which allows human operator to control the whole balancing process.

The proposed balancing algorithm is robust and is capable to bring the link from unknown (eg. some amplifiers could be switched off at beginning) to functional state with bit error rate about 1.0E-12. The balancing takes approximately 3-5 minutes because we measure BER only for several seconds after an each change. It is extremely fast with regard to the time needed to measure the BER with predetermined confidence interval width.

The driving current in the amplifiers was decreased approximately by 23 % from the initial state. We cannot exactly say how much it changed the real lifetime of each pump diode. It depends exponentially on the tempeture. But a possitive impact of a lower driving current to lifetime is evident.

The multichannel spectral device with transmitting analyzed optical signals by the optical fiber for the liquid propellant rocket engine diagnostics

Mikhail A. Vaganov, Oleg D. Moskaletz, St. Petersburg State Univ. of Aerospace Instrumentation (Russian Federation)

Recently spectroscopic methods of diagnostics of the liquid propellant rocket engines for prevention of emergencies become topical. These methods allow to receive information about engine’s condition by carrying out spectral measurement of rocket blast radiation. Such diagnostics is based on tracking appearance of spectral lines of engine’s constructional materials in spectrum of rocket blast radiation.

The multichannel optical spectral device considered in this paper makes the contactless spectrum analysis of optical radiations that allows to use this spectral device for diagnostics of the liquid propellant rocket engines. The novelty of this spectral device lies in application of the fiber-optical bundle and N parallel channels of the spectrum analysis. Each channel contains the narrow-band optical filtration which has been set on the certain wave length. The fiber-optical bundle is used for transmitting analyzed optical radiation on a safe distance for device.

This method of the contactless rocket engine diagnostics allows to except a direct contact of the spectral device with the field of rocket blast radiation and to eliminate negative influence of the engine on the spectral device, for example the acoustic impact.

Such diagnostics is very important for providing flight safety both of civil and military aircrafts.

The results of experimental research are given. These results prove functionality of the multichannel optical spectral device.

The multichannel optical spectral device realizes ideas of patent ? 86734 of the Russian Federation.

Fabrication of subcutaneous veins phantom for vessel visualisation system

Kai Cheng, Doshisha Univ. (Japan); Kazuyuki Narita, Doshisha Univ (Japan); Eiji Nakamachi, Yusuke Morita, Doshisha Univ. (Japan); Norihiro Honda, Kunio Awazu, Osaka Univ. (Japan)

The technique of subcutaneous veins imaging by using NIR (Near Infrared Radiation) is widely used in medical applications, such as the intravenous injection and the blood sampling. In the previous study, an automatic 3D blood vessel search and automatic blood sampling system was newly developed. In order to validate this NIR imaging system, we adopted the subcutaneous veins in the human arm and its artificial phantom, which imitate the human fat and blood vessel. The human skin and subcutaneous vein is characterized as the uncertainty object, which has the individual specificity, non-accurate depth information, non-steady state and hardly to be fixed in the examination apparatus. On the other hand, the conventional phantom was quite distinct from the human’s characteristics, such as the non-multilayer structure, disagreement of optical property. In this study, we develop a multilayer phantom, which is quite similar with human skin, for improvement of NIR detection system evaluation. The phantom consists of three layers, such as the epidermis layer, the dermis layer and the subcutaneous fat layer. We embedded a blood vessel inside the subcutaneous fat layer. We use the intralipid to imitate the optical scattering characteristics of human skin, and the hemoglobin and melanin for the optical absorption characteristics. In this study, we did two subjects. First, we decide the fabrication process of the phantom and confirmed the process was stable. Second, we compared newly developed phantoms with human skin by using our NIR detecting system, and confirm the availability of these phantoms.

8841-44, Session PMon

Thermal shock and stress with infrared optical domes and materials

Youtang Gao, Nanyang Institute of Technology (China)

The development of infrared optical materials is always closely related to the research and exploration of material science. The infrared optical domes bears shock and produces stress when the infrared optical domes mounted on the missile moving at a high speed is shocked by high temperature. According to aerodynamics theory and thermo shock theory, the surge current will be transferred to optical parts through holding up layer and warms the surface of optical parts when infrared optical parts are shocked by high temperature. A compress stress is formed on the hot external surface of optical parts forms and a tension stress is formed on the internal surface or optical parts under the circumstance of the edge of optical parts being fixed. The windows of optical parts become curvature radius of lens with the function of pressure difference which can cause aberration change. The brittle fracture of material will be caused if peak stress is beyond the strength which is permitted for infrared materials. Therefore, limits to design of windows thickness is proposed in this paper.

Near-infrared imaging system for detecting small organic foreign substances in foods

Hiroto Tashima, Tsuneaki Genta, Yuya Ishii, Takeshi Ishiyama, Shinichi Arai, Mitsuo Fukuda, Toyohashi Univ. of Technology (Japan)

Contamination of foods with foreign substances is a serious problem because it often has negative effects on health. However, detecting small organic substances in foods is quite difficult because they are undetectable with traditional inspection apparatus. In this work, we developed new equipment that detects small organic substances at high speed, applying a near-infrared (NIR) imaging technique. The absorption spectra of various foods were measured, and the spectra showed low absorbance at wavelengths from 600 nm to 1150 nm. Considering the observable wavelength of a CMOS camera, which enables high-speed imaging (~30 cm/sec) and has high dynamic range (90 dB), superluminescent diodes (SLD) with a wavelength of 830 nm were selected as a light source. We arranged 40 of the SLDs on a flat panel and placed a diffusion panel over them. As a result, uniformly distributed light with an intensity of 0.26 mW/cm2 was supplied to an area of 6.0 cm x 6.0 cm. Insects (3 mm width) and hairs (0.11 mm diameter) were embedded in stacked sliced ham with a total thickness of 5 mm, and the transmission images were observed. The insects and hairs were clearly observed as dark shadows with high contrast. Furthermore, we compensated the images, using a software developed in this study for eliminating low spatial frequency components in images and improving sharpness and contrast. As a result, the foreign substances were more clearly distinguished in the 5-mm-thick ham. In conclusion, we developed equipment that detects small organic substances in foods, using an improved NIR imaging technique.

Application of the light field for a simulation to evaluate the MTF of optical lens systems using rendering

Shuma Horiuchi, Manabu Yamamoto, Tokyo Univ. of Science (Japan)

Simulation using rendering can evaluate the modulation transfer function (MTF) of optical lens systems and advantages to design a optical lens systems. Rendering is typically used in three-dimensional computer graphics (3D CG) with the ray tracing method. This simulation method corresponds to an experimental measurement of the MTF using bar-target test charts, and therefore allows an analysis of the resolving power of shift-variant optical systems that are difficult to evaluate with conventional methods based on the point spread function (PSF). However many sampling number of rays are necessary to obtain the radiance distribution which is reduced the variance. Therefore the computational time increases in proportion of the analyzed spatial frequency. Then in this paper, we proposed the technique to apply the light field in the method. The technique records the light field which is a function that describes position and direction of rays on the entrance pupil plane of the lens system. The image formation is constructed from the light field with test charts of every spatial frequencies. The computational time that the image formation is constructed is very short as compared to ray tracing in the lens system. Therefore the MTF for each spatial frequency can be obtained very fast. This paper outlines the recording method and the format of the light field.

Holographic recording method using shift multiplexing system with spherical reference beam

Yuta Nagao, Kaito Okubo, Hiroyuki Kurata, Takaaki Matsubara, Manabu Yamamoto, Tokyo Univ. of Science (Japan)

Recently, along with the wider use of high-speed information networks and multimedia, it is increasingly necessary to have higher-density and higher-transfer-rate storage devices. Therefore, research and development into holographic memories with three-dimensional storage areas is being carried out to realize next-generation large-capacity memories. The mainstream of the multiplexing system in the world is the angle multiplexing method however it has some problems for example it costs too much and its control is quite severe. Therefore we studied about shift multiplexing method using spherical reference beam to store data more than angle multiplexing. Generally, there is only one direction to allow multiplexing in shift multiplexing?method, however in this paper we examined about shift selectivity of track direction (x-axis), radial direction (y-axis) and vertical direction (z-axis) of the disk medium. Combining these three different kinds of directions, we found a possible multiplexing way to achieve several tera bits per inch square density recording. In this experiment, we recorded data in the medium which material is photopolymer and 1.5mm thick. In addition, using a high NA objective lens for the reference beam, we experimentally succeed to make data density higher.

A framework of cloud supported collaborative design in optical glass moulds based on aspheric measurement

Yongjian Zhu, Yu Wang, Zhejiang Univ. of Science and Technology (China); Jingxin Na, Jilin Univ. (China); Yanan Zhi, Shanghai Institute of Optics and Fine Mechanics, Chinese Academy of Sciences (China); Yufeng Fan, Zhejiang Univ. of Science and Technology (China)

At present, lens molding (hot pressing) technology has become a popular method to manufacture a lot of small aspheric glass lenses in order to reduce the cost and improve the efficiency. In glass lens molding, the key factor lies in the accurate design of precision optical aspheric moulds. Aspheric mould design includes the top-down design and reversal design. In this paper, a new framework of reversal design is proposed combining with cloud supported collaborative design (CSCD) based on aspheric measurement. The framework is a kind of collaborative platform, which is composed of eight modules, including the computerized aspheric precision measurement module (CAPM), computer-aided optical design of aspheric lens system (CAOD), computer-aided design of lens mould (CAD), computer simulation of lens molding module (CSLM), computer-aided experiments of lens & moulds (CAELM), data analysis module (DAM), optical product lifecycle management module (OPLM) and cloud computing network module (CCNM). In this framework, the remote clients send an improved requirement or fabrication demand about optical lens system through CCNM, which transfers this signal to OPLM. In OPLM, one main server is in charge of the task distribution and collaborative work of other six modules. The first measurement data of aspheric lens are produced by clients or our proposed platform CAPM (laser interferometer or profilometer), then are sent to CAOD for optimization and the electronic drawings of lens moulds are generated in CAD module. According the design drawings, the CSLM could give the lens-molding simulation parameters through FEM software such as MSC. Marc or Deform. The simulation data are used for the second design of moulds in CAD module. In this case, the moulds could be fabricated by diamond turning or grinding in CAELM by ultra-precision machine, and the aspheric lens could be also produced by lens-molding machine in CAELM. At last, the final shape of aspheric lens could be measured

in CAPM and the data analysis could be conducted in DAM module. Through the proposed framework, all the work described above could be performed coordinately. And the optimum design data of lens mould could be realized and saved, then shared by all the work team.

Design for adjustable optical system of liquid filled lens

Dein Shaw, Hui-An Hsieh, National Tsing Hua Univ. (Taiwan)

Most of the image capture modules use flat and rigid sensors, but the flat sensor surface can't match the curvy focal surface of a single lens system perfectly. The error between the off-axial image of flat sensor and the focal surface, call aberration, limits the image quality when the image comes from a lens. One solution is using multiple individual lenses to force the image flat and match the focal surface, but it also causes the whole module hard to be compact. The requirement for higher image quality and less volume of module motives the study of liquid lens and flexible sensor system. In this research, we design a optical integrated module including a liquid-filled lens, a flexible sensor membrane and a self-adjusted optical compensation device. We focus on the optical relationship between the liquid-filled lens and the sensor membrane to make the system has good optical characters. According to compensation function, this module compensates the optical character between lens and sensor membrane to obtain a clear image by adjusting the internal pressure and volume of the liquid in the liquid filled optical system. The curvy sensor membrane has better performance than flat type sensor in both the image quality of MTF, aberration and angle of view for a single lens optical system. The research can be applied in the fields of the adapter lens system of digital camera, self-compensation optical system and security optical devices, etc.

Optical-digital system for spectra analysis from aqueous solutions of textile dyes

Alfonso Padilla-Vivanco, David Villegas-Hernandez, Valente Licona-Carrasco, Univ. Politécnica de Tulancingo (Mexico)

Textile wastewater treatment is still a great environmental problem today. Azo dyes represent the largest class of textile dyes. Due to the large number of aromatic groups present in these molecules and their stabilities, most azo dyes are nonbiodegradable. Many conventional treatment methods have been found to be ineffective for the decolorization and degradation processes. Chemical processes such as chlorination and ozonation are the most frequently used methods for removal of the textile dyes from wastewater. Others process such as flocculation, reverse osmosis, and adsorption onto activated carbon had been examined. However, these processes only transfer the contaminants from one phase to another, and further treatments are required. Namely, the advanced oxidation processes have been extensively investigated. Among these processes, heterogeneous photocatalysis is an emerging destructive technology leading to total destruction of most of organic pollutants. In some cases, the degradation is conducted for dissolved compounds in water with ultraviolet-illuminated TiO_2. Here, the main idea is to implement a spectroscopic system to measure the concentration of textile dyes which are dissolved in aqueous solutions.

8841-51, Session PMon

Analysis and implementation of a digital holographic imaging system for extended objects

Martin Hernández-Romo, Alfonso Padilla-Vivanco, Carina Toxqui-Quitl, Univ. Politécnica de Tulancingo (Mexico)

Holography is the method of capture and reconstruction of 3-D objects, which has numerous applications in optical metrology. Specifically digital holography offers several advantages over classical holography as it is to avoid chemical treatments, object reuse numeric access to the phase and amplitude of the objects. In particular we use an optical system based on off-axis holography interferometer which serves to make the recording of holographic filters from optical images of extended objects and reference beams. Some designs avoids the presence of shadows in the hologram after that the hologram recovery can be calculated from the wavelet filter coefficients and the peak 2D wavelet transform. The object reconstruction can be improved in the ideal case by an coherent imaging system which is difraction limited. Experimentally has been found that a combination of negative and positive lenses can formed images with a acceptable resolution. In this work, the interest is determine the imaging system by means a combination of commercial lenses.

Design of highly-efficient vertical p-n junction type Si optical modulator with low driving voltage

Chan-Min Kang, Jungho Park, Seulki Kim, Jinsik Kim, Korea Univ. (Korea, Republic of)

Vertical p-n junction carrier-depletion type silicon phase modulator with low driving voltage was designed and implemented using Mach-Zehnder interferometer. The free-carrier plasma dispersion effect was considered to increase the electro-optic effect of silicon based modulator. The modulation mechanism is mainly based on the free-carrier plasma dispersion effect in vertical p-n junction. Silicon-on-insulator wafer was used to fabricate the modulator and coplanar strip electrodes were designed to transmit the RF signal with 50 Ω matching. COMSOL Multiphysics and High Frequency Structure Simulator(HFSS) were used to find optimum dimensions of modulator and to simulate RF characteristics of modulator's electrode, respectively. Waveguide in Mach-Zehnder interferometer was designed for single mode operation. The device could be operated with very low π-phase-shift voltage-length ($V\pi L$) of 0.57 V•cm. Driving voltage of a 2 mm long modulator is 2 V and cut-off frequency is up to 25 GHz. Such a highly efficient modulating capability with low power consumption makes the integrated silicon photonic chips for next generation communication networks possible.

Theoretical considerations in radiometer design

José G. Suárez-Romero, Instituto Tecnológico de Querétaro (Mexico)

This work considers typical radiometers that measure the radiance of sources or of some surface (due to reflection). The most important thin in a radiometer is its optical cavity, which defines the solid angle of measurement. In case of instruments that use lenses, lens diameter and focal length define the solid angle. Radiometer design takes care that the solid angle subtended by the optical cavity be minor that the solid angle subtended by the source to be measured, however no considerations are taken on the length of the cavity. In this work it is discussed theoretical limitation in the design of radiometers, particularly the influence of radiometer length (the cavity length). Theory of partial coherence is used to obtain the instrument function and to show how the length of the instrument affects measurements.

Design, fabrication, and metrology of polymer gradient-index lenses for high-performance eyepieces

James A. Corsetti, Anthony Visconti, Kejia Fang, Peter McCarthy, Greg R. Schmidt, Duncan T. Moore, Univ. of Rochester (United States)

High-performance eyepiece designs have been carried out using both spherical and radial gradient-index (GRIN) elements. Eyepiece designs of both geometries are shown to offer superior imaging performance with fewer elements when compared to purely homogeneous systems. These GRIN lenses are formed from monomer diffusion between polymethyl methacrylate (PMMA) and polystyrene (PSTY) during the polymerization process, resulting in a copolymer of the two homogeneous materials.

A process for fabricating spherical GRIN elements is discussed where copolymer axial GRIN blanks are thermally compressed using spherical surface molds. This process curves the nominally-straight isoindicial surfaces of the axial GRIN rod to be consistent with the shape found during optimization of the design. Once compressed, the spherical blanks are diamond-turned for final surface figure and finish. Measurement of the GRIN profile is carried out using the Schmidt immersion technique in a Mach-Zehnder interferometer. Tolerances specific to GRIN elements are identified and determined to be readily achievable using the aforementioned manufacturing process.

The methodology of generating GRIN elements of the radial geometry is also discussed. By pumping the two monomers into a rotating cylindrical chamber (for this purpose, mounted to a lathe) a rotationally-symmetric GRIN profile is formed as a result of the diffusion process. The centrifugal force of the lathe causes the heavier material (PMMA) to settle at the outside of the chamber and the lighter material (PSTY) at the center. Preliminary results for GRIN elements fabricated in this way have been successful and are shown.

8841-28, Session 7

Fabrication of gapless microlenses on spherical surface by multi-replication process

Yi-shiuan Cherng, National Taiwan Univ. (Taiwan)

Artificial compound-eye structure has been studied recently due to its great applications of wide field-of-view imaging and backlight modules. However, fabrication process for microstructures on curvilinear surface has a lot of difficulties since traditional fabrication techniques are planar. In this paper, a simple and low-cost method to fabricate microlenses on spherical surface was demonstrated. Microlenses with high fill factor were formed by thermal reflow technique, followed by multiple replication processes to transfer the microlenses from planar substrate onto spherical surface. During the process, we made a curved mold with concave microlenses, which allowed this method to be duplicable easily. Polydimethylsiloxane (PDMS) elastomer was employed as the material of both microlenses and mold due to its flexibility and transparency for visible light. To prevent microlenses from being damaged during the release procedure, surface treatment using Trichloro (1H,1H,2H,2H-perfluorooctyl) silane was applied before every replication process. Several PDMS domes covered with hexagonal or square microlenses on the surface were fabricated successfully. The diameter of each microlens was about 200 μm and the pitch of array was 220 μm. The radius of curvature of the spherical surface was about 6.2 mm. The uniformity of microlenses was analyzed through the intensity distribution of focused spots. Imaging performance of microlenses was shown, presenting a wider view-angle focusing property. The curved microlens arrays were combined with image sensor, and clear images of objects at different distance are shown. The experimental results showed a high potential for curved microlens arrays being applied to compact mobile camera lens.

SNR parameter test system of MCP In vacuum system

Yafeng Qiu, Nanjing Univ. of Science and Technology (China)

The core component of night vision system is Image intensifier. Research and production for the third generation of low light level image intensifier device are in progress in China. Fourth-generation image intensifier imaging mechanism is under Pre-Research. Screen, microchannel plate and the cathode are the main parts of an image intensifier. The important performance parameters such as resolution and signal-to-noise-ratio(SNR) of image intensifier depend on the Comprehensive performances of screen, the microchannel plate and cathode. Noise characteristic of the microchannel plate (MCP) is an important indicator of the evaluation of image intensifiers, while the present theory suggests that MCP is a major noise source of the image intensifier. In order to detect the MCP-generated noise, a vacuum system and designed the test method of the noise factor of MCP have been established. The noise factor of the MCP is measured using the test set-up with microchannel plate MCP signal to noise ratio parameter detection device in the vacuum system. It is can be used to judge the quality of the MCP scientifically .The experiments verify this test system is advanced, and the test results are reliable. This test system Provide a technical to promote the image intensifier research, and experience to testing other parameters or in other areas of research.

Er3+-doped fiber-based Mach- Zehnder interferometer with mechanically-induced long-period fiber gratings

Grethell G. Perez-Sanchez, José Alfredo Alvarez-Chavez, Ctr. de Investigación e Innovación Tecnológica (Mexico)

There are a few semi-conductor, multiple-wavelength, high-performance sources already available for ITU-T channel generation in DWDM systems. The 200 Ghz barrier has imposed a limitation to such sources. An option for overcoming such a limitation is a super-continuum, all-fibre source working in the amplified spontaneous emission regime. Amplified spontaneous emission from an Er-doped fiber spectrum is well-suited for broadband applications as its optical nature permits emission, amplification and detection within at least 100nm bands, via channel selection through either mode-locking or saturable absorber methods. Consequently, in this work we propose a preliminary Er-doped fiber based Mach-Zehnder interferometer, made with mechanically-induced, long-period, fiber gratings, which generates a fringe pattern ranging from 1450 to 1650 nm, which could be employed in modern DWDM systems. The aforementioned MZI characteristics are of great interest for the development of all-fiber devices that could produce and even select a few channels in the 1550nm region, the transmission window of interest for ultra-long haul optical communication systems. A full set of optical characterization and results will be included in the presentation.

8841-32, Session 7

Further results in measuring water ice buildup on optical components in cryogenic vacuum chambers

Trevor M. Moeller, L. M. Smith, Frank G. Collins, James P. Rogers, The Univ. of Tennessee Space Institute (United States); Jesse M. Labello, Heard S. Lowry, Dustin H. Crider, Arnold Engineering Development Ctr. (United States)

Experiments presented in a previous paper [1] established proof-of-principle that water, the most prevalent contaminant in high-vacuum cryogenic systems, initially collects on the surfaces of optical components as a thin film of ice, and thus can be detected and its thickness measured via multiple-beam thin-film interference phenomena. In those earlier experiments, a molecular sieve zeolite in a canister external to a vacuum chamber served as a water source, while the buildup of ice was measured using a HeNe laser beam reflected off the surface of a mirror with a quartz crystal microbalance (QCM) used for verification of the mass accumulation. Additional experiments have improved upon the techniques used earlier and provided further insight into the ice accumulation process. Use of a shorter wavelength (450 nm) laser in conjunction with a first-surface gold mirror produced greater depth of modulation and thus increased signal-to-noise ratio in the light interference. Data reduction using cross-correlation analysis over single-period interference records provided more accuracy and precision in the ice thickness measurements. Ice buildup under varying pressure and temperature ranges established baseline conditions for transparent thin-film deposition, and the transition to ice fracture and specular reflection. These recent experiments have demonstrated that the optical monitoring of ice accumulation via multiple-beam interference is applicable over a wider range of mass and thicknesses than the conventionally-used QCM method.

[1] T. M. Moeller, L. M. Smith, F. G. Collins, J. M. Labello, J. P. Rogers, H. S. Lowry, D. H. Crider, “Measurement of the accumulation of water ice on optical components in cryogenic vacuum environments,” Optical Engineering, Vol. 51, No. 11, November 2012, pp. 115601-1 to 115601-8.

Ionic polymer metal composite to achieve optical zoom function in a compact camera

Wei-Shiang Chen, National Taiwan Univ. (Taiwan)

Nowadays, there are many popular electronic devices consist of optical focus zooming systems. It is the trend to minimize optical systems in the portable devices. For this purpose, we used deformable mirrors in optical systems that can make them thinner and slighter. The Ionic-Polymer Metal Composite (IPMC) is the critical component in our design of the deformable mirror. It has good bending feature and can be driven at low voltage (less than 5 volts). The IPMC fabrication processes contain three steps: acid clean, initial compositing process and surface electrode plating process. We use Nafion in the IPMC fabrication. In order to create the desirable electrode shape, we make the Nafion covered by a shadow mask to make the elliptic pattern electrode. After the IPMC is completed, we deposit aluminum on one side as a reflective surface to finish our deformable mirror. In our experiment, we put the two deformable mirrors in the optical zoom module. This module consists of three biconic mirrors and the two deformable mirrors. When we applied voltages on deformable mirrors, the reflective light is successfully focused after the deformation of elliptic IPMC. At the tele-end, the curvatures of two deformable mirrors are all zero. While at wide-end, the first deformable mirror is actuated to convex in 25 diopter (m-1) and the second deformable mirror is actuated to concave in 65 diopter (m-1). The zoom ratio of this module can achieve to 1.7 times. The deformable mirror can be changed from flat to 65 diopter (m-1) by about 3 volts.

Utilizing perkinelmer infrared spectroscopy to achieve a full spectrum at ppm level

Chunhong Xiao, PerkinElmer, Inc. (United States)

Infrared spectroscopy has been widely used for qualitative and quantitative analysis, including incoming raw material quality control and impurity&contamination identification, however, it has always been a challenge to get a full spectrum at ppm level. Some ppm quantitative analysis was done based on limited spectral information within the high wavenumber region or a particular small region. With limited spectral range, it is not feasible to do qualitative analysis. In this presentation, we explored the IR application on material detection and identification at ppm level with a high sensitivity MCT detector system.

One of the materials studied here is caffeine. Caffeine is widely used in food and drug, including all kinds of drinks, tea, soda and coffee. Depending on the category, it is regulated differently by FDA. The safe level defined by FDA is 0.02% or less, which is 200ppm or less.

Spectra were taken at 4cm-1/4co-adds with PerkinElmer MCT IR spectrometer. 300 ppm caffeine solution was made by adding 300 microgram caffeine into 10 milliliter dichromethane (DM). 30 ppm caffeine was diluted from the 300 ppm solution. Caffeine spectra at ppm level were retrieved by subtracting the spectrum of 300 ppm caffeine in DM from DM spectrum (Figure 1).

Some other materials were also studied at ppm level in different solvents. With a full spectrum of the ppm level solutions, now IR can be used for not only quantitative but also qualitative analysis for low level detections.

White light holograms: made from scratch

Dennis Tierney, Xavier Univ. (United States); Erna Frins, Univ. de la República (Uruguay); B. Hils, Wolfgang Dultz, Johann Wolfgang Goethe-Univ. Frankfurt am Main (Germany); Heidrun Schmitzer, Xavier Univ. (United States)

Scratch holograms are produced by engraving circular patterns with dividers on a polished surface. When illuminated with a more or less point like light source, each circular groove reconstructs one image point. The light source does not need to be coherent and can be very broadband. Wheatstone described this effect already in the 19th century and it was rediscovered in the 1990's; particularly William Beaty developed this effect further to display three dimensional images. Scratch holograms are not based on the interference of light, but rather on the conservation of the light's momentum during scattering from a groove. This scattering is similar to diffraction, but without the secondary effect of interference. Scratch holograms are independent of the wavelength and can therefore be considered real white light holograms. A theoretical modelling using Born's approximation supports this interpretation. To demonstrate this experimentally we use the fact that the path of light is reversible and show that circular patterns can be fabricated with a stream of small particles coming from the nozzle of a sand blast unit exiting a tilted slit.

System of polarization correlometry of biological liquids layers polycrystalline structure

Taras Boychuk, Bukovinian State Medical Univ. (Ukraine); Alexander Ushenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Ozar Mincer, Bukovinian State Medical Univ. (Ukraine); Pavlo O. Angelsky, Natalia Bodnar, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Liliya Bizer, Bukovinian State Medical Univ. (Ukraine); Boris Oleinichenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

As a base for modeling the optical properties of blood plasma we use the conception of anisotropy

- blood plasma can be considered as a two-component amorphous-crystalline structure;
- optically anisotropic – luquid-crystalline phase consisting of a set of optically uniaxial birefringent liquid crystals of various types: spherulitic globulins and scicular albumins with circular and linear birefringence.

It is shown that statistic approach to the analysis of complex degree of mutual coherence distributions of blood plasma are effective for differentiation of acute and gangrenous conditions have been analytically substantiated.

From the obtained data about the coordinate distributions of CDMC of blood plasma layers both groups can see that:

- The average and dispersion of CDMC distributions differ insufficiently within 1.75 – 2.5 times.
- The asymmetry values of CDMC distributions of the investigated samples differ by 2.5 - 4 times; the excess values – by 1.5 – 3.5 times.

A model of the effusion polycrystalline networks optical anisotropy of appendicitis has been suggested and the method of CDMC diffentation of linear (a phase shift between the orthogonal components of the laser wave amplitude) and circular (the angle of rotation of the polarization plane) birefringence is developed.

8842-33, Session PMon

The system spatial-frequency filtering of birefringence images of human blood layers

Taras Boychuk, Bukovinian State Medical Univ. (Ukraine); Alexander Ushenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Ozar Mincer, Bukovinian State Medical Univ. (Ukraine); Pavlo O. Angelsky, Boris Oleinichenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Natalia Bodnar, Liliya Bizer, Bukovinian State Medical Univ. (Ukraine)

As a base for analyses of processes providing formation of polarization-inhomogeneous images of human blood, we use the next optical model:

- optical properties of human blood are determined as those of a two-component structure – формені епементи - пπазма;
- crystalline component of forming elementa are optically;
- blood plasma crystalline component is an architectonic net consisting of amino-acid liquid crystals with linear birefringence.

Our analysis of the parameters determined experimentally has shown that the following parameters are diagnostically sensitive in observation of inflammatory processes:

- statistical moments of the third and the fourth orders in distributions for the amount of extreme values of phase shifts delta=0.5? in laser images for human blood health's and sick patients – differences between them reach 1.7 - 2.4 and 2.4 - 4.1 times;
- distributions of extreme values of phase shifts for the phase maps describing human blood for healthy and sick patients are, respectively, statistical and fractal;

Thus, one can conclude:

1. Human blood, independently of their physiological state, contains phase-modulating optically anisotropic network of biological crystals.
2. Ascertained and grounded is a set of criteria for phase diagnostics

of pathological and cancer processes as being based on statistical (statistical moments of the first to the fourth orders) and fractal (fractal dimensionality) analyses of phase distributions in laser images of human blood.

8842-34, Session PMon

Fabrication of universal all-optical gates and switches by implementation of optical cavity based on Brewster-angle phenomenon

Akbar Rahmani-Nejad, Maharan Engineering Corp. (Iran, Islamic Republic of)

We used Brewster's angle phenomenon and an optical cavity as a decisive method to implement all-optical logical gates and switches. A microcavity is attached by a micro-fiber coupler to two optical signal. The first signal that is called control signal is coupled such that the optical signal travel es inside the cavity parallel to the main axis and to be confined. The second optical- that is parallel polarized- signal is coupled slightly upper than Brewster's angle. This is called the data-signal. An optical crystal having refraction index "n" is inserted in the optical cavity. When there is no control optical signal, a portion of data-signal is reflected back. by inducing control signal refractive index of the crystal inside the cavity increases to about "0.2-0.3n" more than previous value this is enough to increase Brewster's angle about several degrees that results to complete deletion of reflected parallel-polarized beam of data-signal. Due to enhancing specification of microcavity the threshold intensity is completely feasible and economical. On the other hand due to crucial asymptotic characteristics of Brewster's angle phenomenon, there is no reflected data-signal that can be considered as commercial optical switch or optical NOT gate. By inducing of two control signal and fixing the level of required change of refractive index corresponding to sum of the intensity of two control signals a NAND all optical gated is fabricated. There is a SOA to amplify reflected control to non-reflected incident beam and a polarizer when there is no control signal.

Singular microscopy of biological layers for diagnostics and classification of their optical properties

Taras Boychuk, Ozar Mintser, Bukovinian State Medical Univ. (Ukraine); Alexander Ushenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

This work is aimed at ascertaining the possibilities to diagnose and classify phase-inhomogeneous layers (PhIL) of various types (surface-scattering, subsurface-scattering and bulk-scattering ones) by determination values and ranges for changing the statistical (moments of the 1-st to 4-th orders), correlation (autocorrelation functions) and fractal (logarithmic dependences for power spectra) parameters that characterize coordinate distributions for polarization-singular states in PhIL laser images.

8842-36, Session PMon

Multiparameter correlation microscopy of blood plasma polycrystalline networks in the diagnosis of cancer tissues of female reproductive system

Vitaliy N. Balazyuk, Galina Koval, Volodimir G. Ushenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

To characterize the degree of consistency of parameters of the optically uniaxial birefringent protein nets of blood plasma a new parameter – complex degree of mutual anisotropy (CDMA) is suggested. The technique of polarization measuring the coordinate distributions of the complex degree of mutual anisotropy of blood plasma is developed.

A model of the effusion polycrystal networks optical anisotropy of appendicitis has been suggested and the method of CDMA diffentation of linear parameters (a phase shift between the orthogonal components of the laser wave amplitude) and circular (the angle of rotation of the polarization plane) birefringence.

8842-37, Session PMon

System of space: Frequency filtering of linear and circular birefringence in cancer diagnosis

Mykola Raranskiy, Galina Koval, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

Our research is aimed at designing an experimental method of Fourier's laser polarization phasometry of the layers of human effusion for an express determining the potentialities of diagnostics of pathological changes in the endometrial tissue of female reproductive system.

The main idea of such an approach lies in the fact that spatial-frequency structure of the Fourier form of the laser image of the polycrystalline network of human effusion is different for its large scale albumin and small scale protein structures. Therefore, through space-frequency filtering one can mainly select either low-frequency (with linear birefringence) or high-frequency (with circular birefringence) components which by means of reverse Fourier transformation can be converted into corresponding "separated" laser images.

8842-38, Session PMon

Polarization-phase imaging of biological fluids polycrystalline structure

Mikhailo Sakhnovskiy, Vitaliy N. Balazyuk, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

Our research is aimed at designing an experimental method of Fourier's laser polarization phasometry of the layers of human effusion for an express diagnostics during surgery and a differentiation of the degree of severity (acute - gangrenous) appendectomy by means of statistical, correlation and fractal analysis of the coherent scattered field.

A model of generalized optical anisotropy of polycrystal networks of albumin and globulin of the effusion of appendicitis has been suggested and the method of Fourier's phasometry of linear (a phase shift between the orthogonal components of the laser wave amplitude) and circular (the angle of rotation of the polarization plane) birefringence with a spatial-frequency selection of the coordinate distributions for the differentiation of acute and gangrenous conditions have been analytically substantiated.

8842-39, Session PMon

Multidimensional Mueller-matrixes microscopy of biological phase-inhomogeneous layers

Alexander V. Dubolazov, Artem O. Karachevtsev, Maxim V. Sidor, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

Specific features of the formation of local and statistical polarization structures of laser radiation scattered in phase-inhomogeneous layers (PIL) of biological tissue (BT) were studied. The distribution of azimuth and eccentricity of boundary field polarization was found to correlate with the orientation-phase structure of multifractal PIL. A method of polarization phase reconstruction of BT architectonics was suggested.

Polarization fractallometry of 2DSi parameters of Mueller matrixes of BT images is effective in diagnostics of changes of coordinate distributions of orientations and optical anisotropy of their architectonic nets, formed by the collagen bundles.

8842-40, Session PMon

A novel and compact spectral imaging system based on two curved prisms

Yunfeng Nie, Xiangli Bin, Jinsong Zhou, Yang Li, Academy of Opto-Electronics (China)

As a novel detection approach which simultaneously acquires two-dimensional visual picture and one-dimensional spectral information, spectral imaging offers promising applications on biomedical imaging, conservation and identification of artworks, surveillance of food safety, and so forth. A novel moderate-resolution spectral imaging system consisting of merely two optical elements is illustrated in this paper. It can realize the function of a relay imaging system as well as a 10nm spectral resolution spectroscopy. Compared to conventional prismatic imaging spectrometers, this design is compact and concise with only two special curved prisms by utilizing two reflective surfaces. In contrast to spectral imagers based on diffractive grating, the usage of compound-prism possesses characteristics of higher energy utilization and wider free spectral range. The seidel aberration theory and dispersive principle of this special prism are analyzed at first. According to the results, the optical system of this design is simulated, and the performance evaluation including spot diagram, MTF and distortion, is presented. In the end, considering the difficulty and particularity of manufacture and alignment, an available method for fabrication and measurement is proposed.

8842-1, Session 1

Cluster eye camera using microlenses on parabolic surface

Hui-Kai Shen, Guo-Dung John Su, National Taiwan Univ. (Taiwan)

There are two main types of imaging systems that exist in nature: the single aperture eyes and the compound eyes. Usually, cameras and most of artificial imaging systems are similar the single aperture eyes. But compound lenses can be more compact than single lenses. Our design is based on insect compound eyes, which also have a wide field of view (FOV). With the rise of micro-optical techniques, fabricating compound lenses become easier than before. The simplest structure of a curved microlens array is making microlenses on a parabolic surface. In this paper, we proposed a multi-channel imaging system, which combining the principle of the insect compound eye and the human eye. The optical system enables the reduction of track length of the imaging optics to achieve miniaturization. By the aid of optical engineering software of ZEMAX, the multi-channel structure is simulated by a curved microlens array, and we used Hypergon lens as main lens to simulate the human eye, which can achieve the purpose of the wide FOV. With this architecture, each microlens of a microlens array transmits a segment of the overall FOV. The partial images that are separately recorded in different channels are stitched together to form the final image of the whole FOV by software processing. A 2.9 mm thin imaging system with 59 channels with 76° FOV is optimized using sequential ray tracing of ZEMAX on a 4.8 mm x 3.6 mm image plane.

8842-2, Session 1

Relating transverse ray error and light fields in plenoptic camera images *(Invited Paper)*

Jim Schwiegerling, The Univ. of Arizona (United States); J. Scott Tyo, College of Optical Sciences, The Univ. of Arizona (United States)

Plenoptic cameras have emerged in recent years as a technology for capturing light field data in a single snapshot. A conventional digital camera can be modified with the addition of a lenslet array to create a plenoptic camera. The camera image is focused onto the lenslet array. The lenslet array is placed over the camera sensor such that each lenslet forms an image of the exit pupil onto the sensor. The resultant image is an array of circular exit pupil images, each corresponding to the overlying lenslet. The position of the lenslet encodes the spatial information of the scene, whereas as the sensor pixels encode the angular information for light incident on the lenslet. The 4D light field is therefore described by the 2D spatial information and 2D angular information captured by the plenoptic camera. In aberration theory, the transverse ray error relates the pupil coordinates of a given ray to its deviation from the ideal image point in the image plane and is consequently a 4D function as well. We demonstrate a technique for modifying the traditional transverse ray error equations to recover the 4D light field of a general scene. In the case of a well corrected optical system, this light field is easily related to the depth of various objects in the scene. Finally, the effects of sampling with both the lenslet array and the camera sensor on the 4D light field data are analyzed to illustrate the limitations of such systems.

8842-3, Session 1

Miniaturized optical-fiber endoscope without inertial scan for simultaneous imaging and laser microsurgery

Jost Adam, Univ. of California, Los Angeles (United States) and Christian-Albrechts-Univ. zu Kiel (Germany); Philipp Metz, Martina Gerken, Christian-Albrechts-Univ. zu Kiel (Germany); Bahram Jalali, Univ. of California, Los Angeles (United States) and California NanoSystems Institute (United States)

Minimally invasive procedures as used in colonoscopic, arthroscopic, thoracoscopic or neurologic surgeries benefit from a reduced size of endoscopic devices. Spectrally encoded imaging has been proposed as a way to implement miniaturized endoscopy, as only a small-diameter single fiber is needed. Recently, a single-fiber-based device performing simultaneous confocal microscopy and high-precision laser microsurgery (SECOMM) was demonstrated. SECOMM achieves a 2D spatial dispersion by the use of a virtually imaged phased array (VIPA) spectral disperser, in conjunction with a reflective diffraction grating, creating a one-to-one mapping between spatial coordinates and optical wavelength. In this contribution we propose a highly miniaturized optical design of SECOMM based on a VIPA and a perpendicularly aligned volume holographic grating embedded between two prisms (GRISM). A solid glass VIPA produces several overlapping diffraction patterns at a high angular dispersion (x-direction). These are fanned out in y-direction by the GRISM producing a 2D-angular dispersion often referred to as “spectral shower”. Using an imaging lens the angular dispersion is finally mapped into position space producing a specific field of view. Here, we theoretically investigate the spectral shower in angular units and provide a systematic device parameter analysis for the proposed axial design. A center wavelength of 800 nm is considered for use with a TI:sapphire laser as the light source. However, our endoscope design can also operate at other wavelengths such as visible and infrared. The best system performance is obtained by using a high optical bandwidth combined with a low grating period and a low VIPA tilt.

8842-4, Session 1

Advances in optical design and optimization of miniature zoom optics with liquid lens element

Yi-Chin Fang, National Kaohsiung First Univ. of Science and Technology (Taiwan); Cheng-Mu Tsai, Kun Shan Univ. (Taiwan)

An optical design of 2X optical miniature zoom lens with liquid lens elements and optimization method: discrete lens groups shifts (DLGS) has been presented in this research. Two liquid elements are applied to minimize the overall length of zoom optics. Moreover, a compensative optimization method with assistance of Genetic Algorism is introduced in this research with a new concept of DLGS, which not only solve the complicated problem of liquid optics itself but also improve the performance of optics. Genetic algorithms (GA) written in CODE V plays the role at finding out the appropriate parameters such as curvatures, thicknesses, glass materials and etc. Besides, one table with great lens groups shifts by GA would be created to move the lens groups on the optimal positions of different zooms. As a result, the DLGS optimization method associated with the GA optimization improve the zoom lens performance averagely 40% better than traditional ones.

8842-5, Session 2

On the use of special aperture stops

Wenjing Zhao, Cornelius F. Hahlweg, Hendrik Rothe, Helmut-Schmidt Univ. (Germany)

The use of special aperture stops offers a wide variety of image conditioning and pre- processing possibilities. The mathematical description and modeling of the resulting effects depends on the question whether the illumination is coherent or incoherent, which then leads to fourier-optical or geometrical optical views. The paper is dedicated to a theoretical discussion of the commonalities, in other words the question where the fourier view is to be applied in the non-coherent case. The discussion is inspired by investigations of shadowgraph techniques, which deliver the practical examples as well.

8842-6, Session 2

Rear pupil imaging system for extended depth of field

Hsieh Sheng-Hsun, Zih-Hao Lian, National Chiao Tung Univ. (Taiwan); Chong-Min Chang, MaxEmil Photonics Corp. (Taiwan); Chung-Hao Tien, National Chiao Tung Univ. (Taiwan)

Recently, extended depth-of-field, super-resolution and light-field techniques have become more and more important in many digital imaging systems, and those studies can be incorporated into pupil engineering. Pupil engineering modulates the amplitude or phase of pupil position, making the point spread function and modulation transfer function have some advantageous properties. For extended depth of field (DoF), the pupil of system employs wavefront coding mask to engineer the point spread function be insensitive to defocus. Using post processing such as Wiener decoding filter, we can restore the intermediate image with high fidelity. However, pupil engineering cannot suit all optical systems. Since the modulating element affects the performance from different optical positions, such as entrance pupil, exit pupil or aperture stop. Changing these specific positions will change the modulation strength. In this paper, we proposed a best solution called rear pupil imaging system (RPI system) to overcome this issue. Rear pupil imaging system (RPI system) optimizes pupil position at rear position to extend depth of field. It satisfies the linear shift invariant by modulating pupil position while keeps the point spread function to constant. The spot size is dependent on the coding strength, and the coding strength is dependent on the extended ability. RPI system can utilize heavy coding and huge extended ability than other optical systems. The simulation result shows DoF was extended over three times by RPI system than other extended DoF optical systems.

8842-7, Session 2

Special imaging techniques employing polarization, aperture stop, and phase effects

Wenjing Zhao, Carsten Daniel Skaloud, Helmut-Schmidt Univ. (Germany); Cornelius F. Hahlweg, Helmut-Schmidt Univ. (Germany) and bbw Hochschule (Germany); Hendrik Rothe, Helmut-Schmidt Univ. (Germany)

In the paper static and time variant photographic techniques for observations of pressure, density and stress pattern in transparent media are discussed. Special attention is drawn on the observation of dynamic stress effects in extended media under polarized illumination. While a homogeneous stress distribution along the optical axis leads to the well established planar ‘opticon’ configuration, the quantitative observation of 3D distributions might demand the separation of slices or planes along the direction of observation. A typical example is the stress distribution caused by irregular bodies embedded in a block of gleatin. The separation can be realized by intentional strict reduction of depth of field using special aperture stop configurations. In the paper theoretical and practical aspects and especially the fourier-optical vs. geometrical-optical implications of special aperture stops in non-coherent illumination shall be discussed. Various practical examples of quasi-static and short processes are included. A corresponding paper focussing on the vibration pattern in guitars delivers further examples.

8842-8, Session 2

Laser autostereoscopic projection system

YuChang Wang, Junejei Huang, Delta Electronics, Inc. (Taiwan)

The current autostereoscopic projection system is accomplished by array projectors. It is easy in the optical realization but leading a drawback with size. Another type is to place the shutter on the screen. It saves the volume but reduces the efficiency depending on how many views to be produced. The shutter in the lens aperture has the same efficient problem, too. To overcome these problems, a full HD autostereoscopic projector based on the lens aperture switching type is proposed. It has RGB laser sources and can produce 16-view or even higher stereoscopic image.

This system cancels the shutter in the lens aperture, it is accomplished by the opti-mechanism itself. The specific light on the lens aperture comes from the point on the DMD is reflected to different angles. The proper angle of light is generated in the object side by the relay and folding system. The UHP lamps or the LED are difficult to constrain the rays in a relative small cone angle. For this reason, the laser is applied to the design. The very small etendue of laser is good for this architecture. The rays are combined by dichroic filter from RGB laser sources then forming and expanding to the mirror. The mirror is synchronized with DMD by the DSP control system. The images of different views are generated by DMD and specific position of the mirror. By the double lenticular screen, the lens aperture is imaged to the observer’s viewing zone. The 3D scene is created.

8842-9, Session 2

Transient and spectral analysis of power modulation of light in natural and artificial situations

Cornelius F. Hahlweg, Helmut-Schmidt Univ. (Germany) and bbw Hochschule (Germany); Cornelia Weyer, Norddeutsches Forschungsinstitut e.V. (Germany)

For investigations on the perception and physiological effects of power modulation of light in conjunction with acoustic stimuli – like in entertainment shows - as described in a corresponding paper a reference

device was desirable. So a broadband spectrometer for analysis of the power modulation of light up to several kHz versus the light wavelength of the visual spectrum was designed and tested. Besides the primary intention the gathered multispectral data sets can be used for identification of artificial light components in natural environments. The paper deals with design issues and verification problems and delivers some representative experimental results.

8842-10, Session 3

Energy-minimized design in all-optical networks using unicast/multicast traffic grooming

William S. Puche, Javier E. Sierra, Ferney O. Amaya, Univ. Pontificia Bolivariana (Colombia)

The increased bandwidth required by applications today, tends to raise the amount of optical equipment, for this reason, it is essential to maintain a balance between the wavelength allocation, available capacity, number of optical equipment, such so as to achieve the lowest power consumption Optical green to work with. You could say that we propose a model that minimizes energy consumption, using unicast / multicast traffic grooming in optical networks.

The proposed model will take into account the results consuming and wavelength in an optical network capacity taking into account multiple sessions and which is more effective comparing between unicast and multicast, this ratio having analyzed the various optical components of the network , which will be compared with real devices and display energy consumption which occurs in the network. This allows large research centers or telecommunications companies in the region, determine which model could go to the needs of these and make it a significant energy efficiency and cost savings.

8842-11, Session 3

On modal analysis of coupled non-identical optical gradient waveguides

Nikolai D. Espinosa, Army Polytechnic School (Ecuador); Jesus Vila, Univ. del Pais Vasco (Spain); Tatiana Acosta, Marcelo Urbina, Paola Leon, Christian N. Vega, Army Polytechnic School (Ecuador)

Using a new analytical scalar approximation called modal theory (alpha method) we obtain the numerical analysis of propagation constants and field modes of two non-identical optical waveguides.

The results to be obtained will be valid for arbitrary coupled waveguides as well as for coupled identical waveguides.

Wave mode calculation and plotting will be done under a MatLab® environment, considering different coupling variables for both structures and different distances between the center of the fiber optic cores and plane wave guide.

8842-12, Session 3

ILP model for greenfield WDM PON network design based on physical layer constraints

Germán V. Arévalo, Univ. Politécnica Salesiana (Ecuador); Javier E. Sierra, Univ. Pontificia Bolivariana (Colombia)

The optimal dimensioning of the network is one of the main problems in the design of a WDM PON. Traditionally, the network size is determined by the traffic demand, the user density, the active and passive equipment capacity and some physical restrictions like the attenuation in the optical path. However, the physical layer limitations become more relevant in WDM PON transmissions, specially when employing very high data rates like 10 Gb/s or beyond. In this paper we propose a novel physical-layer-restrictions based integer linear programming (ILP) model for greenfield next generation 10 Gb/s WDM PON network design.

The results of the model are validated by means of the computational results obtained with CPLEX studio - OPL software.

The proposed ILP model takes into account not only the attenuation of the signal in the optical path but also, through the use of the data obtained by the optical systems simulation software OptSim, we take in to account the restrictions imposed by other phenomena like dispersion, cross talk and some non linear effects typically present in a WDM optical transmission.

8842-13, Session 3

Scenario analysis for performance evaluation of free-space quantum and classical communication channels

Edith García, Univ. Autónoma de Baja California (Mexico); Josué A. López Leyva, Arturo Arvizu-Mondragon, Ctr. de Investigación Científica y de Educación Superior de Ensenada (Mexico); Eduardo Alvarez Guzman, Univ. Autónoma de Baja California (Mexico); Francisco J. Mendieta, Agencia Espacial Mexicana (Mexico)

In order to asses a free space optical links, using a Cassegrain telescope for both classical (i.e. coherent and direct detection) and quantum (coherent, Dolinar-Kennedy system) several scenarios were analyzed. This analysis was conducted through a software tool that uses some specific parameters imposed by the environmental condition and hardware used, such as: the pointing and tracking errors, turbulence, modulations schemes, and visibility, among others; in order to obtain the general performance parameters of the simulated link, such as: channel capacity, bit error rate, transmission time and the photons number. The tool developed allows the user to produce useful information for either a clearly and precise way to assess possible success of the implementation of the free space optical link, or a way to identify the phenomena that might suggest hardware adjustments to improve the overall performance of the system. Results allow the revision of the expected link performance for quantum key distribution systems; although it is possible to use it for general optical quantum communications systems.

8842-14, Session 3

Evaluation and optimization of the Savitzky-Golay smoothing filter for noise reduction in thin film interference signal analysis

Petros I. Stavroulakis, City Univ. London (United Kingdom) and Sencon (UK) Ltd. (United Kingdom); Panos Liatsis, City Univ. London (United Kingdom); Nicholas Tipping, Paul Craddock, Sencon (UK) Ltd. (United Kingdom)

In this work, we present a comparison between Savitzky-Golay filtering and the traditional treatment of subtracting a dark signal to reduce noise from spectra acquired by a spectrometer in an adaptive thin film thickness measurement system where integration time needs to be varied for each measurement. In detail, it is found that due to the nature of the spectral interference signal, Savitsky-Golay filtering implemented indiscriminately with a static bin size has the potential of reducing the interference fringe height unequally throughout the spectrum. Thus when the period of the fringes is comparable to the bin size, the Savitzky Golay filtered signal results in a 'damped sinusoidal' with the height of the interference fringes steadily increasing with wavelength. The classical dark signal subtraction technique on the other hand does not produce such defects but it is discussed that dark signal removal cannot be easily used as a general-purpose solution for stand-alone adaptive systems (such as those used in industrial applications) because dark signals are spectrometer-dependent and would need to be stored for all of the integration times, since the magnitude of the noise also depends on integration period. Moreover, dark signals should be ideally acquired before a signal is taken, to account for any possible noise drift. Finally, we show that by applying a dynamic and gradual variation of the Savitzky-Golay bin parameters across the signal, the Savitsky-Golay technique can be used as a general-purpose noise reduction technique for thin film interference signals collected by a spectrometer in an adaptive system.

8842-15, Session 4

The unique sound of the Univibe, part II: transient behaviour

Cornelius F. Hahlweg, Helmut-Schmidt Univ. (Germany) and ITB Berlin (Germany); Hendrik Rothe, Helmut-Schmidt Univ. (Germany)

(The paper is intended for the upcoming session on optics and music)

The Univibe is an effect pedal mostly used by electric guitar players. It is based on an opto-electronically controlled all-pass chain. In last year's paper on the subject an idealized system model was derived, which lead to deeper discussion of the musical consequences of the effect in terms of harmonic analysis of single tones and chords in clean and distorted mode. As a direct continuation the present paper now deals with the transient behaviour of the device. The transient response is essential for understanding the special sound character, the reaction on picking techniques and the interaction with certain instruments like the Fender Stratocaster. Therefore the system model is expanded and the pulse response of the idealized time invariant system is derived. Also the classic Strat floating vibrato and pickup configurations are investigated particularly with regard to their correspondence with the Univibe pulse response. The talk will contain the sound examples cited in the paper, as well as practical demonstrations.

8842-16, Session 4

Visualizing sound: music in slow motion

Cornelius F. Hahlweg, Wenijing Zhao, Hendrik Rothe, Helmut-Schmidt Univ. (Germany)

The core of the present paper is derived from recent investigations of high speed photographic techniques using schlieren, cross polarization and other special methods for visualization of material effects as described in a corresponding paper. Here we use high speed video under polarized illumination for dynamic stress analysis over the audible spectrum. As a first example the vibration modes of various body shapes of electric guitars, which were modeled from acrylic glass, are visualized and compared. Further the stress caused by cantilever during reproduction of phonograph records on classic record players is investigated, which leads to the question of record wear and the usefulness of optical record players as discussed in last year's session. The talk will be supported by footage, sound samples and practical demonstrations.

8842-17, Session 4

Perception of power modulation of light in conjunction with acoustic stimulation

Cornelia Weyer, Norddeutsches Forschungsinstitut e.V. (Germany) and G&S Gesundheit und Sicherheit für Betriebe GmbH (Germany); Cornelius F. Hahlweg, Helmut-Schmidt Univ. (Germany) and bbw Hochschule Berlin (Germany); Harald Gercke-Hahn, G&S Gesundheit und Sicherheit für Betriebe GmbH (Germany)

An ongoing study concerning the perception of LF power modulated light in conjunction with acoustic stimulation, as found for instance in music entertainment shows, is discussed. The paper deals with the test device and the study design. The perception of light flicker has been an issue TV and monitor screen design as well in arc welding for decades. As a basis for the intended investigations the cut-off frequency and threshold modulation depth over the peripheral angle are measured for a group of test persons, the physiological effects are monitored using ECG. The results are compared to measures found in literature to validate the test conditions. The test conditions then are extended by acoustic stimuli. While a coherent combination of slow deep light modulation with acoustic pulses of the same frequency is typical for light accompaniment of music – like spot lights and drums being in step – the basic question here is the perception of such coherence near and above the flicker perceptibility. Further the effect of acoustic stimuli at audible harmonics of the flicker and the perceptibility of slight incoherence or detuning are questioned. First results are presented and discussed. The presentation contains practical examples.

8842-18, Session 5

Toleranced freeform optical design with extended sources using ray targeting *(Invited Paper)*

R. John Koshel, Photon Engineering, LLC (United States) and College of Optical Sciences, The Univ. of Arizona (United States); Steve Mulder, Photon Engineering, LLC (United States)

Freeform optics are limited to design with simplified source models. With a realistic extended source, the resulting design is limited by the ability to hold the source and optic to the desired tolerances. For example, a design is made around the nominal emitter characteristics, such as an encapsulated LED die. This process is called tailoring. Positioning and spectral output can vary appreciably for these emitters. A method to design optics with extended sources with tolerances taken into account is presented. This method uses targeted raytracing to specify particular points on optical surfaces. In the method presented here, the source is represented instead as a collection of non-ideal sources, each weighted according to the statistics of the dimensional and color variations that are expected in the source. The design is iteratively developed over its extent where each step accounts for the tolerances of the multitude of potential ray paths through the optics. The end result is to design optics that are tolerant to the predicted level of error, while maintaining the desired level of efficiency and distribution at the target. This method notably samples the differential étendue aspects of the source as it propagates through the system. Upon solution of the iteratively generated reflector control points, an optimization run can be performed to improve performance. We will present the example applications of mating encapsulated LEDs to secondary optics that incorporate tolerancing of LED die size and placement and LED color variation.

8842-19, Session 5

Characterization of flexoprinting patterns

Lukas Pescoller, Peret GmbH (Italy); Cornelius F. Hahlweg, Helmut-Schmidt Univ. (Germany) and bbw Hochschule Berlin (Germany) and Norddeutsches Forschungsinstitut e.V. (Germany)

In continuation of last year's paper on distorting optics for inspection of 2 1/2D surfaces methods for the characterization and quality control of flexoprinting plates using image processing are discussed. Special attention is drawn to the mottle of the patterns, which is a major quality and responsible for the macroscopic perception of the resulting print product. A fast and rugged method is the interpretation of the density and coherence of the traces of minimum correlation, derived from the auto-correlation function. Mathematics, reliability and scaling problems are discussed, practical examples are included.

8842-20, Session 5

Helical apodizers for tunable hyper Gaussian masks

Jorge Ojeda-Castaneda, Sergio Ledesma, Cristina M. Gomez-Sarabia, Univ. de Guanajuato (Mexico)

For a wide range of applications, it is desirable to engineer the axial impulse response of an optical system. To that end, it is convenient to exploit McCutchen theorem, which relates through a Fourier transformation the axial complex amplitude distribution with the angular average of the generalized pupil function /1-3/.

Here, we apply McCutchen theorem for designing a pair of helically modulated amplitude masks, which work as a pair. By introducing an in-plane rotation, between the elements of the proposed pair, one can control the damping coefficient of any embedded hyper Gaussian apodizers /4/. We show that the proposed optical device is useful for tuning either radially varying masks or annularly varying masks. We analyze the influence of the proposed pair on the axial irradiance distributions, generated by optical systems with extended depth of focus /5/.

8842-22, Session 6

Designing an acousto-optical spectrometer for Guillermo Haro astrophysical observatory

Alexandre S. Shcherbakov, Adan O. Arellanes, Vahram Chavushyan, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

The Guillermo Haro astrophysical observatory (Mexico) realizes the investigations of galaxies, interstellar medium, and extra-solar planets in the visible and near-infrared range 400 – 1100 nm. Actually, the Boller-Chieves spectrometer is exploited there with mechanically removable optical filters and diffraction gratings with the stroke density 50 – 600 lines/mm of the aperture about 9 x 9 cm and provides the accuracy 9.6 - 0.8 A/pixel. Unfortunately, the required mechanical manipulations, i.e. changing the diffraction gratings with various resolutions and then recalibrating the spectrometer within studying even the same object, are inconvenient and mean wasting rather expensive time for astrophysical observations. This is why exploiting an acousto-optical cell as a dispersive element in that spectrometer is desirable. Potentially, it realizes tuning the spectral resolution and the range of observation electronically, breaking those imperfections down and excluding filters. In this case, the spectrometer's optics collimates light on the mechanically fixed acousto-optical cell. Currently, we consider two crystalline materials for similar cell providing the stroke-density 300 lines/mm along the aperture 9 cm. It is the lithium niobate ($LiNbO_3$)-crystal excited by the longitudinal acoustic mode along the [100]-axis at the frequency 2 GHz, giving total losses ~5.4 dB/aperture. Then, one can take the bismuth germanate ($Bi_{12}GeO_{20}$)-crystal using the shear acoustic mode along the [110]-axis at 0.53 GHz with the losses ~6.3 dB/aperture. The figures of acousto-optical merit for these materials are neighboring and promise efficiencies of operation sufficient for observations. Finally, the proposed acousto-optical spectrometer with the reduced dimensions and weight provides the spectral resolution 5-15 A.

ESPRESSO APSU: Simplify the life of pupil slicing

Paolo Conconi, Marco Riva, INAF - Osservatorio Astronomico di Brera (Italy); Stefano Cristiani, INAF - Osservatorio Astronomico di Trieste (Italy); Denis Mégevand, Francesco Pepe, Observatory of Geneva (Switzerland); Alexander Cabral Pereira, Univ. de Lisboa (Portugal); Paola Spanó, Filippo M. Zerbi, INAF - Osservatorio Astronomico di Brera (Italy)

This paper presents the Espresso Anamorphic pupil Slicer (APSU) implementation. ESPRESSO, the Echelle SPectrograph for Rocky Exoplanets and Stable Spectroscopic Observations, will be installed on ESO's Very Large Telescope (VLT). The light coming from the Telescope through a Coudè Focus of all the Four Telescope Units (UTs) will be collected by the Front End Unit that provides Field and Pupil stabilization and injects the beams into the Spectrograph fibers. The light is projected into the spectrograph through a bungle of fibers.

In this work we will present the design and trade off for the pupil slicing system introduced in order to increase the resolving power, effectively decreasing slit width. It's based onto simplified optical component that introduce large anamorphism while keeping low aberrations by means of cylindrical optics. We describe here the trade off between slicing through two adjacent squared doublets and two achromatic prisms. The opto-mechanical performance are here presented and described. The slicer mirror stack in the spectrograph focal plane is composed of four cylinder mirrors (curvature in the local YZ-planes) mounted together, aligned, and fixed. Trade-off between cylinder and flat mini-mirror are descirbed evaluating manufacturability and costs Vs performances

8842-24, Session 6

Novel optical technique to measure sub-pixel responsivity of various imaging sensors

Abhuit Chatterjee, Space Applications Ctr. (India)

Effective pixel area measurement of various CCD and CMOS imaging sensors is an important activity for flight model camera payload design in various remote sensing satellites. Knowledge of active pixel area and two dimensional responsivity profiles enables the system designer to decide upon optical parameters for achieving diffraction limited performance from integrated camera payload. We have designed and developed a test setup to generate circular light spot of 4µm at wavelength range from 400nm to 1100nm and to perform two dimensional pixel scan of various CCD & CMOS sensors. This paper describes optical system design aspects, final opto-mechanical configuration, test results carried out on 1Kx1K frame transfer CCD having pixel dimension 13µmx13µm and the capabilities of test setup apart other than pixel area measurement.

8842-25, Session 6

Range reconstruction model for 3D gated imaging

Ching Seong Tan, Multimedia Univ. (Malaysia); Tommy Chai, Univ. Tunku Abdul Rahman (Malaysia); Xin Wang, Monash Univ. (Malaysia); B. M. Goi, Univ. Tunku Abdul Rahman (Malaysia); Sing

Yee Chua, Monash Univ. (Malaysia); Gerald G. Seet, Nanyang Technological Univ. (Singapore)

Range gated imaging is a remote sensing acquisition which involves the emission of laser pulse and an intensified camera to gate the reflected laser pulse. Range accuracy has always been an issue especially when highly accurate reconstructed model is expected as the final outcome. The reflected pulse profile and pulse instability are among the issues that affected the range accuracy where general solution such as constant offset is not applicable. In this paper, a study to estimate a more accurate model for the reflected pulse profile has been carried through experiments. T Location-Scale model has been proposed to replace the Gaussian model as the general assumption for range-gated image formation model. The improvement on range accuracy which is around 0.3% has been verified through simulation based on the acquired samples. The series of range-gated images can be reconstructed into three-dimensional through range calculation. The accuracy of the three-dimensional model has been proven to be affected by the number of gated images used in the reconstruction.

8842-26, Session 7

Stereo-matching image-processing by selected finite length edge line-matching on least square method

Akira Akiyama, Kanazawa Technical College (Japan); Nobuaki Kobayashi, Kanazawa Institute of Technology (Japan); Eiichiro Mutoh, The Society of Japanese Aerospace Companies (Japan); Hideo Kumagai, Tamagawa Seiki Co., Ltd. (Japan)

We have studied the stereo matching image processing by selected finite length edge line matching on least square method for ranging the object and image recognition.

The two images from a pair of the stereo imagers may have some image deformation each other with the rotation, expansion and contraction of edge line. To make a flexible stereo matching we construct the finite length edge line as a simple standard and search the similar edge line segment in another image.

The construction of the selected finite length edge line as a standard follows the next 5 steps. The first is blocking the binary auto focused high pass filter image by Daubechies wavelet transformation. The second is thinning each blocked image by Hilditch thinning method. The third is tracing each thinned edge line by clockwise or counterclockwise direction and making the sequential edge line. The forth is applying the least square regression analysis of the first order polynomial on finite pixel length edge line on each point of edge line and evaluating the regression error by standard deviation and inclination of edge line. The last is selecting the part of edge line having the appropriate least square regression property.

Selected finite length edge line matching is evaluated by the root mean square computation of the difference between two edge lines under coinciding two start pixel points and the inclination value of two regression lines. From this evaluation we made the flexible and reasonable edge line stereo matching. And it is possible to compute the range information and realize the shape of object edge. To make good quality image captures for the current processing, a pair of imagers are equipped with controllable aperture mechanism.

8842-27, Session 7

A monochromatic recursive convolution finite-difference time-domain algorithm and its application in simulation of arrays of metal nano-particles

Saswatee Banerjee, Sumitomo Chemical Co., Ltd. (Japan)

A special class of finite-difference time-domain (FDTD) algorithm, called recursive convolution (RC) FDTD, is developed to simulate metals in visible domain [1]. Conventionally, RC-FDTD is implemented for pulsed light sources. This requires that the analytical model of permittivity should fit the handbook permittivities (derived from experimental measurements) closely over broadband of wavelengths. This is not an easy task and the choice of a particular model depends on the metal being simulated.

We developed a monochromatic version of RC-FDTD [2]. This algorithm uses the 1st order Drude model [1] to evaluate the convolution operation needed to make FDTD stable for metals for which the real part of permittivity is negative. Unlike the conventional RC-FDTD, the Drude parameters are computed at each wavelength of the incident light using the corresponding handbook value of permittivity. Hence, this version of RC-FDTD allows us to use the handbook permittivity values at all wavelengths of operation.

Here, we study the dependence of localized surface plasmon resonance (LSPR) properties of arrays of nano-particles on the shape, size and number of particles in the array and the interparticle distance [3]. We compute the extinction spectra of linear nano-particle arrays using the RC-FDTD method. For such arrays, the peak of the extinction spectra shifts toward the longer wavelengths as the interparticle distance decreases.

Modelization of the whispering gallery mode in microdisk and microgear resonators using a toeplitz matrix formalism for single-photon source

Moez Attia, Amor Gueddana, Rihab Chatta, SUP'COM (Tunisia); Alain Morand, IMEP-LAHC (France)

The work presented in this paper develops a new formalism to design a microdisks and microgears structures. The main objective is to study the optic geometric parameters influence on the microdisks and microgears structures resonance behavior. This study is conducted to choice a resonance structure with height quality factor Q to be associated with Quantum dot to form a single photon source. This new method aims to design resonant structures are simpler and requires less computing performances than FDTD and Floquet Block methods. This formalism is based on simplifying Fourier transformed and using toeplitz matrix writing. This new writing allows designing all kind of resonance structures with any defect and any modification. In other study we have design a quantum dot emitting a photon at 1550 nm of the fundamental mode, but the quantum dot emits other photons at other wavelengths. The focus of the resonant structure and the quantum dot association is the resonance of the photon at 1550 nm and the elimination of all other photons with others energies. In this paper we design a GaAS microdisk and microgear and we compare the quality factor Q of this two structure and we conclude that the microgear is more appropriated to be associate to the quantum dot and increase the probability P1 to obtain a single photon source at 1550 nm and promotes the obtaining of single photon. The performance improving of the resonant structure is able to increase the success of quantum applications such as quantum gates based on single photon source.

8843-1, Session 1

Determination of angular momentum content in partially coherent beams through cross correlation measurements

Adad Yepiz Escalante, Benjamin Perez-Garcia, Raul I. Hernandez-Aranda, Tecnológico de Monterrey (Mexico); Grover A. Swartzlander Jr., Rochester Institute of Technology (United States)

A means to measure orbital angular momentum in a partially coherent beam is demonstrated by using a wavefront folding interferometer. This interferometer allows us to study the cross correlation function of a partially coherent vortex beam. It is shown that the cross correlation function possesses ring dislocations which are related to the topological charge of the partially coherent vortex, exhibiting a one to one correspondence between the number of rings and the value of the topological charge, thus providing a direct measure of the orbital angular momentum.

8843-2, Session 1

Measuring topological charge using Stokes parameters

Benjamin Perez-Garcia, Dorilian Lopez-Mago, Adad Yepiz Escalante, Raul I. Hernandez-Aranda, Julio C. Gutiérrez-Vega, Tecnológico de Monterrey (Mexico)

An alternative method to experimentally measure the topological charge of a vortex beam is presented. The method is based on the number of polarization singularities arising in the superposition of two off-axis Laguerre-Gauss beams having orthogonal polarizations. The experimental setup consists of a modified Mach-Zehnder interferometer which provides control over the polarization structure by allowing us to introduce lateral displacements as well as relative phase variations between the two arms of the interferometer. A comparison between theoretical and experimental results is done with very good agreement. This method offers an alternative for measuring orbital angular momentum content in a beam without the need of interfering with a reference plane wave. The dynamics of polarization singularities are also studied experimentally.

8843-3, Session 1

Optical fields with tunable transverse intensity fluxes arranged over a semi-circle

Adrian Ruelas, Manuel G. Jurado-Taracena, Julio C. Gutiérrez-Vega, Tecnológico de Monterrey (Mexico)

Accelerating and Airy beams are of great interest as they remain diffraction free while experiencing a quadratic shift along propagation, transporting intensity in the transverse plane over a straight line. This work presents optical fields that transport intensity in the transverse plane over a continuum of directions arranged over a semi-circle, having the possibility of controlling both the angular distributions of relative intensity and spatial frequency. We construct these beams via a superposition of plane waves with distinct longitudinal and transverse wavevector components, forming periodic and quasi-periodic intensity profiles along propagation. The on-demand light patterns presented here are expected to find applications in optical trapping as Airy beams and nondiffracting beams have previously found.

8843-4, Session 1

Generating and analyzing non-diffracting vector vortex beams

Yanming Li, North Carolina State Univ. (United States); Angela Dudley, Thandeka I. Mhlanga, CSIR National Laser Ctr. (South Africa); Michael J. Escuti, North Carolina State Univ. (United States); Andrew Forbes, CSIR National Laser Ctr. (South Africa)

We report the first experimental generation and analysis of non-diffracting vector vertex beams by using a Spatial Light Modulator (SLM) and an azimuthal birefringent plate (q-plate). The SLM generates scalar Bessel beams and the q-plate converts them to vector vortex beams. Both single order Bessel beam and superposition cases are studied. The polarization and the azimuthal modes of the generated beams are analyzed. We examine the azimuthally varying polarization by recording the beam profile through an analyzer. We measure the orbital angular momentum (OAM) of each polarization component by doing a modal decomposition on the beams separated by a linear and a circular polarization beam splitter. The results are in good agreement with theory, showing different OAM in orthogonal circular polarizations and the corresponding OAM superposition in linear polarizations. The full analysis concludes that our generated beams have cylindrical polarization and carry polarization dependent orbital angular momentum.

8843-5, Session 1

Techniques to sort Bessel beams *(Invited Paper)*

Angela Dudley, Thandeka I. Mhlanga, Andre McDonald, CSIR National Laser Ctr. (South Africa); Martin P. Lavery, Univ. of Glasgow (United Kingdom); Filippus S. Roux, CSIR National Laser Ctr. (South Africa); Miles J. Padgett, Univ. of Glasgow (United Kingdom); Andrew Forbes, CSIR National Laser Ctr. (South Africa)

In this work we will present two techniques for the measurement of superimposed higher-order Bessel beams. In the first technique we will outline a simple approach using only a spatial light modulator and a Fourier transforming lens to decompose the OAM spectrum of an optical field. We test this approach on symmetric and non-symmetric superpositions of non-diffracting higher-order Bessel beams. Our second procedure consists of two refractive optical elements which perform a Cartesian to log-polar coordinate transformation, translating helically phased beams into a transverse phase gradient. By introducing two cylindrical lenses we can focus each of the azimuthal modes associated with each Bessel beam to a different lateral position in the Fourier plane, while separating the radial wave-vectors in the image-plane.

8843-6, Session 2

Beam shaping by volume phase structures in photo-thermo-refractive glass *(Invited Paper)*

Marc SeGall, Daniel Ott, Ivan B. Divliansky, Julien Lumeau, Sergiy Mokhov, Boris Y. Zeldovich, Leonid Glebov, Univ. of Central Florida (United States)

Multiple applications of lasers require various forms of beam shaping for optimal use. This may take to form of aberration reduction, mode conversion, etc. Conventionally these shapers are produced by phase masks which utilize spatial profiling of the surface of an optic. Here we demonstrate phase masks which are recorded in the volume of photo-thermo-refractive (PTR) glass. PTR glass is a photosensitive glass which provides refractive index change of up to 10^-3 after exposure to near

UV radiation followed by thermal development. Due to its low absorption and high damage threshold it is well suited for many laser systems including high power systems. This material has been successfully utilized previously for the holographic recording of volume diffractive elements (volume Bragg gratings), which have been used in applications for spectral and angular narrowing, coherent and spectral beam combining, and the stretching and compression of laser pulses. To record phase masks in PTR glass we expose the glass to UV radiation which has been transmitted through binary amplitude masks. These may be used to produce binary phase masks or grayscale phase masks depending on the profile of the amplitude mask. Volume phase masks have been used to generate Fresnel lenses of varying focal lengths, convert Gaussian beams to higher order Hermite-Gauss and Laguerre-Gauss modes, to produce optical vortices whose topological charge is controlled by the total phase incurred, and to produce aberration-correcting elements.

8843-7, Session 2

The effect of SLM dependent dispersion on spatial beam shaping

Dirk-Mathys Spangenberg, Stellenbosch Univ. (South Africa); Angela Dudley, CSIR National Laser Ctr. (South Africa); Andrew Forbes, CSIR National Laser Ctr. (South Africa) and Univ. of KwaZulu-Natal (South Africa)

Spatial light modulators (SLM) used for spatial modulation of lasers are often used in conjunction with very narrow bandwidth laser light where diffractive dispersion could be approximated as a constant. It is known that diffractive dispersion is inversely proportional to wavelength and this effect can be compensated for depending on the optical set-up. SLMs use birefringent liquid crystal (LC) pixels each with adjustable refractive index at a specific polarization. The range of the adjustable refractive index is wavelength dependent. This adds an additional SLM dependent dispersion. Note that we distinguish between diffractive dispersion and SLM dependent dispersion. SLMs are therefore calibrated in order to have linearly adjustable phase retardation of light incident on the pixels between zero and two pi for a specific wavelength. It is therefore unavoidable when using the same SLM, to do beam shaping of a source which emits multiple wavelengths or a wide bandwidth, that the device will not modulate all wavelengths between zero and two pi. We numerically and experimentally investigate the effect of SLM dependent dispersion on spatial modulation of light incident on a 2D SLM. We further discuss why it is possible to modulate multiple wavelengths between zero and two pi despite SLM dependent dispersion.

8843-8, Session 2

Generation of high-order Bessel beams using an axicon zoom system

Carlos López-Mariscal, U.S. Naval Research Lab. (United States); Fred M. Dickey, FMD Consulting LLC (United States)

We present a novel optical system capable of producing scalable Bessel beams. The system is composed of two positive axicons - which produce the characteristic annular spectrum of Bessel beams -, and a spiral phase plate, which imprints the respective azimuthal phase modulation. The axicon pair and lens are configured as a zoom lens system that provides the scalability in the spectrum. A brief analysis of the system's operation is presented along with design examples and computational simulation of the system's performance.

8843-9, Session 2

Steerable diffraction limited line illumination system using deformable mirror

Koichi Taniguchi, Hitachi High-Technologies Corp. (Japan); Dae Wook Kim, College of Optical Sciences, The Univ. of Arizona (United States); Kei Shimura, Hitachi High-Technologies Corp. (Japan); James H. Burge, College of Optical Sciences, The Univ. of Arizona (United States)

Many scientific and industrial applications often require high performance optical systems utilizing spatially shaped illumination patterns of laser beams. Precisely shaped line illumination can be used for various line scanning systems or surface inspection devices. In order to achieve the highest resolution or superior signal to noise ratio limited by the fundamental theory, a diffraction limited illumination optical system (e.g. > 0.7 Strehl ratio) gives the narrowest illumination line width determined by the system's NA (Numerical Aperture) value. For high precision and in-factory industrial applications, the Diffraction Limited Line Illumination (DLLI) needs to be controlled in three dimensional space rapidly as the target object under the illumination may not always aligned with respect to the illumination system. A steerable DLLI system with three degrees of freedom (i.e. axial displacement, rotation, and tilt) is developed using an adaptive optics system. By electronically controlling the Zernike based surface shapes of the deformable mirror, the DLLI in free space is actively positioned and oriented with high accuracy and precision within ~10 milliseconds time scale. The geometrical optics based mathematical model to control the Zernike modes of the deformable mirror and the performance of a bench-top proof-of-concept system will be presented with experimental data and analysis results.

8843-10, Session 2

A measurement system of large size laser beam intensity temporal-spatial distribution based on CCD diffuse transmission imaging

Miao Pang, Univ. of Electronics Technology and Science of China (China) and Institute of Applied Electronics (China); Jian Rong, Univ. of Electronics Technology and Science of China (China); Xuewen Yuan, Xueyan Gao, Shan Zhou, Institute of Applied Electronics (China)

Laser intensity temporal-spatial distribution means laser beam spatial profile vs. time, through which we can get the nonuniformity, centroid, centroid jitter and beam quality of the laser beam. So it is particularly important to diagnose and evaluate the performance of laser system. We design a measurement system to measure large size laser beam intensity distribution based on CCD diffuse transmission imaging. The measurement principle of the system is presented. The configuration of the measurement system is summarized. There is a highlighting information on the design of diffuse target. The methods of spot geometry distortion rectifying and nonuniformity rectifying are detailedly described. The correction method of the laser spot geometry distortion based on uniting pixels is detailed, by which a mapping is set up between sampling unites and CCD pixels; uniform light source is used to correct the nonuniformity of the responses of the unites. After correction, we can get the exact laser spot. The test results are given, which validate correctness of the method. It provides a new way to measure large size laser profile. The design can measure two laser beam of different wavelength at the same time. The method can provide profile quantitative measurement with high resolution and laser power measurement with high accuracy, which is of great significance for practical engineering applications.

8843-12, Session 3

Beam shaping to generate uniform "laser light sheet" and linear laser spots

Alexander V. Laskin, Vadim V. Laskin, AdlOptica Optical Systems GmbH (Germany)

Generation of "Laser Light Sheet" beams and linear laser spots

characterized by uniform irradiance distribution is important in various laser techniques like Particle Image Velocimetry (PIV), Laser-Induced Fluorescence (LIF), hardening, annealing, cladding, uniform laser illumination of linear spatial light modulators. This task can be successfully solved with using refractive beam shaping optics of field mapping type in combination with additional optical components. Due to their unique features: low output divergence, high transmittance, flatness of output phase front and irradiance profile, as well as extended depth of field, the refractive field mappers provide freedom in further manipulation of intensity profile and shape of output beam. Typically design of refractive field mapping beam shapers has circular symmetry; therefore to create linear spot shapes it is suggested to apply anamorphic optical components like cylinder lenses, prism pairs, etc. The combined beam shaping systems allow achieving very high aspect ratio, up to 1:1000, of linear spots with simultaneous providing extended depth of field, i.e. it is possible to realize a “Laser Light Sheet” characterized by keeping uniform intensity of linear spot over extended distance along optical axis.

This paper will describe some design basics of refractive beam shapers of the field mapping type and optical layouts for creating linear laser spots and “Laser Light Sheet”. Examples of real implementations will be presented as well.

8843-13, Session 3

Active optical system for laser materials processing

Oliver Pütsch, André Temmler, RWTH Aachen (Germany); Peter Loosen, RWTH Aachen (Germany) and Fraunhofer-Institut für Lasertechnik (Germany)

Laser materials processing applications increasingly take full advantage of the utilization of active optical systems. Beside better process efficiency due to improved energy coupling the targeted, dynamic variation of the intensity distribution within the working zone facilitates the development of new methods and techniques for laser materials processing. A totally new approach for the structuring of metallic surfaces is the utilization of laser radiation for structuring by remelting. In contrast to the established techniques, no material is removed but reallocated by the active control of the phase transition of the melt pool. The fabrication of custom textures takes full advantage of this new approach as it facilitates the quick generation and the processing of extended topographies along with reduced production time. Structuring by laser remelting demands the active variation of optical properties since it requires the sophisticated modulation of the laser energy within the working zone. An increased number of degrees of freedom have to be changed during process runtime what makes the optical system design most challenging. An optical set-up has been developed that enables the superposition of cw and pulsed laser beams in the working zone. Piezoelectric driven mirrors allow for the deflection of the laser spots of several microns within the dynamic range of kilohertz. The cw beam is splitted into two shares of intensity that are actively attenuated by retardation plates and polarization coupling. A maximum degree of flexibility is gained by the integration of three tailored zoom-telescopes to vary the spot sizes.

8843-14, Session 3

Dynamic holography for extended object beam shaping

Abbie T. Watnik, Paul S. Lebow, U.S. Naval Research Lab. (United States)

We describe a laboratory experiment to improve the energy-on-target for an extended object. A 532 nm laser beam illuminates a wide area. The initial low-signal return from the target is detected in an off-axis holographic arrangement. The target phase recovered from the hologram is imprinted on an SLM to reshape the beam for the next laser pulse. With each iteration, the gain is increased as more light hits the intended target. We have developed a technique to modify the SLM phase to prevent oversharpening of glints and other high intensity return signal points that cause the beam to collapse to a single point with further iterations. We present laboratory results to verify this approach and demonstrate the increased gain resulting from this dynamic beam-shaping.

8843-15, Session 3

Analysis of the wavefront distortion in the transparent conductive film pockels cell

Fanlin Meng, Dean Liu, Shanghai Institute of Optics and Fine Mechanics (China)

Transparent Conductive Film Pockels Cell(TCFPC) contains an electro-optical crystal and two sapphire substrates deposited with conductive film. Passing through one sapphire substrate, the electro-optical crystal, and another sapphire substrate, the distortion of the wavefront occurs. Theoretically, two sapphire substrates coated with conductive film make uniform electric field distribution, however, the uniformity of the electric field is influenced by the unevenness of the surface. In addition, the phase modulation become uneven when the surface of the electro-optic crystal in the uniform electric field is uneven. In this paper, we analyze the relationship between the electric field and the substrate. Simulations are conducted on the distortion of the wavefront by the electro-optic crystal profile to provide theoretical basis for processing sapphire substrate and electro-optic crystal.

8843-16, Session 4

Beam shaping unit for micromachining *(Invited Paper)*

Alexander V. Laskin, AdlOptica Optical Systems GmbH (Germany); Nerijus Šiaulys, ALTECHNA Co. Ltd. (Lithuania); Gintas Šlekys, ALTECHNA R&D Ltd. (Lithuania); Vadim Laskin, AdlOptica Optical Systems GmbH (Germany)

Uniform irradiance distribution of laser spot is highly advisable in various micromachining techniques like scribing, PCB and Through-Silicon Via (TSV) drilling, repair techniques in display making technologies. Scanning over whole working field with using popular 2- and 3-axis galvo mirror scanners is another important part of microprocessing systems. Therefore, combining of beam shaping optics, converting Gaussian to flattop (uniform) laser beam profile, with scanning optical heads is an insistent technical task. To provide flattop irradiance profile it is suggested to apply field mapping refractive beam shaping optics piShaper being characterized by some important features: low output divergence, high transmittance, extended depth of field, capability to work with TEM00 and multimode lasers, as result providing a freedom in building various optical systems. De-magnifying of flattop laser beam can be realized with using imaging technique; the imaging optical system to be composed from F-theta lens of scanning head and additional collimating system to be used right after a piShaper. One of the problems in this approach is implementation of compact design of the collimating part. As a solution it is suggested to apply a specially designed Beam Shaping Unit (BSU) to be installed between a laser and a scanning head and providing: conversion from Gaussian to flattop laser beam irradiance profile, compact collimator design, and functions of laser beam adjustment and adaptation to a laser and a scanning head used in particular equipment. There will be considered design features of refractive beam shapers piShaper and BSU, examples of optical layouts to generate flattop laser spots, which sizes span from several tens of microns to millimetres. Examples of real implementations and results of material processing will be presented as well.

8843-17, Session 4

Beam-shaping-diffuser-based fiber injection for increasing stability of industrial robotic laser applications

Todd Lizotte, Hitachi Via Mechanics (USA), Inc. (United States); Fred M. Dickey, FMD Consulting LLC (United States)

This paper documents the investigation of a diffuser based fiber injection system and its successful implementation into a robotic industrial process used within the automotive industry. This is a new concept based on the idea that a diffuser that has the angular radiation pattern matching the NA of the fiber can be used to approximate the field pattern at the face of a mode filled fiber. The research considered two approaches to this problem. The two related approaches to the problem were developed conceptually and analytically. The first is an implementation that would consist of illuminating the diffuser with a uniform spot having the same shape as the fiber core and imaging the illuminated spot onto the fiber face. The other approach is the use of a far-field (Fourier transform) diffractive element with a transform lens. This paper will provide an overview of the analytics and testing for the two concepts and the final implementation of the design into a square core fiber optical beam delivery system. Further detail will be shared with the performance of the design when integrated within a multi-axis robotic arm, which has six degrees of freedom. These results will include how the fiber injection system improved laser beam stability during process operations, in comparison to traditional simple lens injection methods.

Laser beam characterization with digital holograms

Andrew Forbes, CSIR National Laser Ctr. (South Africa); Christian Schulze, Daniel Flamm, Friedrich-Schiller-Univ. Jena (Germany); Angela Dudley, CSIR National Laser Ctr. (South Africa); Michael Duparré, Friedrich-Schiller-Univ. Jena (Germany)

We show how laser beam characterization may be done in real-time with digital holograms. We illustrate the power of the techniques by applying them to a variety of laser sources, from fibers to solid-state.

8843-19, Session 4

Customized intracavity generation of high-order mode Laguerre-Gaussian beams with graded-phase mirrors

Lizhi Dong, Ping Yang, Wenjin Liu, Hu Yan, Shuai Wang, Bing Xu, Institute of Optics and Electronics (China)

High-order mode Laguerre-Gaussian (LG) beams are characterized by phase singularity, orbital angular momentum, and larger mode volumes, thus they have attracted a great deal of attentions in both optical and physical communities and are considered as the solutions of certain technological problems. These beams are traditionally formed with extracavity beam shaping techniques with computer generated holograms or spatial light modulator. In recent years intracavity generation of high-order mode LG beams are proposed for higher efficiency and output power through altering the optical pump distribution, inserting absorbing wires and modifying the reflectivity of the output coupler. We present intracavity formation of high order mode LG beams with customized intensity and phase profiles using phase graded mirrors. Although phase-graded mirrors were originally proposed for generating fundamental mode beams with super-Gaussian profiles, we prove that they can also be used to form high-order mode LG beams. In this paper we first introduce the principles of this approach. Then we calculated the first several eigenmodes of the resonator containing the designed phase graded mirror using a 2-D matrix method, and found that the mirror could effectively make the desired field distribution as the fundamental mode of the laser cavity with sufficient mode discriminations. After that we give examples of generating LG beams of several different high-order modes with customized field distributions. In all these cases the designed GPM could effectively form the desired beams. At last we analyze the effects of some perturbations including misalignment, decenter, cavity length variation and imperfection of the graded-phase mirror, and the proper tolerances are discussed.

8843-21, Session 4

Coherent combining of four 100W slab lasers with high beam quality

Hong Yan, Yidong Ye, Qingsong Gao, Xudong Pan, Guohui Li, China Academy of Engineering Physics (China); Tang Jian Zhou, Institute of Applied Electronics (China); XiaoJun Wang, Institute of Applied Physics and Computational Mathematics (China); Peng Du, Yuan Liao, Li Chen, Fei Tian, China Academy of Engineering Physics (China)

Coherent beam combination (CBC) is an effective way to improve the output power and beam quality of laser system. In this paper, we report a coherent combining of four slab lasers with total output power of 400W. Long strip slab laser beam is shaping into square beam using special beam expander which could remove the enormous astigmatism aberration caused by thermal distortion of the slab amplifier. Up to 85% fill factor is achieved by two-dimensional splicing system with small splicing gap. Compact optical system with high sampling frequency is designed to detect the optical axis of four slab lasers. Fast steering mirror (FSM) system driven by piezoelectric ceramics is applied to stabilize four laser beams. When the FSM system is working, the root mean square error of the optical axis is significantly reduced to be less than 2 microradians. The piston phase of four lasers is locked by a fast dithering system based on FPGA using stochastic parallel gradient descent algorithm. When the phase is locked, the peak intensity of the farfield spot under long exposure is increased by 3.8 times, reaching 95% of the ideal case. Thanks to the CBC system the beam quality is improved remarkably, and BQ of the combined laser beam is as good as 1.26. More than 50% of the total energy is locked into the main slob when the phase lock system is on close loop. The experimental results suggest that higher energy CBC could be achieved using the technology presented here.

8843-29, Session 4

A novel interpretation of the integrator

Andrew Stockham, LightWorks Optical Systems (United States)

This paper presents what the author hopes will be a novel interpretation of the integrator, and draws unique comparisons between two types of integrator: the microlens array based imaging beam integrator and the integrating tube, or light pipe, for which a quality factor has been derived.

8843-22, Session PMon

Differential time delay line network for optical controlled beam forming

Jianfeng Sun, Lijuan Wang, Liren Liu, Ya'nan Zhi, Yu Zhou, Shanghai Institute of Optics and Fine Mechanics (China)

Due to the restriction of the aperture effect and the aperture transverse delay, it is very difficult to get large instantaneous bandwidth under wide scan range for a conventional phased array radar. Optical controlled beam forming network (OCBFN) technology can solve this problem. The key of the OCBFN is the optical true time delay line network. In this

paper, we proposed a new differential time delay line network based on the free-space integrated prism array technology. The new method can realize any linear time delay for the space multi-beam radar. Furthermore, the time delay can be adjusted very easily. In order to validate the new method, we design a 4*4 differential time delay line network whose the time delay range is from 0ps to 100ps.

8843-23, Session PMon

Formation and propagation of Bessel beams: practical considerations

Michael Soskind, West Windsor-Plainsboro High School South (United States); Rose Soskind, Rutgers, The State Univ. of New Jersey (United States); Yakov G. Soskind, DHPC Technologies (United States)

Bessel beams belong to a class of propagation invariant, structured beams, and are used in various applications, including particle micro-manipulation, optical coherence tomography, optical metrology, and high resolution microscopy. In practice, Bessel beams are based on the interaction of optical fields with finite lateral dimensions produced by finite aperture optical components, such as axicons.

In this paper, we discuss the formation and propagation characteristics of Bessel beams based on various input field distributions, including Gaussian, vortex, and flat-top fields of finite lateral dimensions. We present the influence of beam forming optics imperfections and component misalignments on the shape of the resulting Bessel beams. We also explore the influence of input field apodization on the properties of Bessel beams. Our results demonstrate that even modest apodization levels of the input field distributions can significantly reduce undesirable axial intensity oscillations in the resulting Bessel beams.

8843-24, Session PMon

Producing Bessel beams based on incoherent superposition of laser fields

Michael Soskind, West Windsor-Plainsboro High School South (United States); Rose Soskind, Rutgers, The State Univ. of New Jersey (United States); Yakov Soskind, DHPC Technologies (United States)

Bessel beams are employed in various applications, including particle micro-manipulation, optical coherence tomography, optical metrology, and high resolution microscopy. Bessel beams are formed from the interaction of optical fields with finite lateral dimensions produced by finite aperture optical components, such as axicons.

In this paper, we discuss the formation and propagation characteristics of Bessel beams based on input field distributions defined by Laguerre-Gaussian beams of different orders. We present the influence of the beam order on the shape and the axial intensity distribution of the resulting Bessel beams. One of the limiting factors in the applications of Bessel beams is related to the variations in the axial intensity distribution of the produced beams. We show that incoherent superposition of input Laguerre-Gaussian beams of different orders can resolve the above limitation and produce Bessel beams with uniform peak intensity distributions over an extended axial distance.

Diffracted fields by slit-shape transmittance curves

Javier Silva-Barranco, Gabriel Martinez-Niconoff, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

The transmittance curves describing effects important in the behavior of the diffracted fields generated by coherent illumination. However, when is realized a spatial transform of the transmittance curve, this can be done by rotating the screen, for example a circle curve, the projection is an ellipse and the diffraction field is no more a soft transformation. In this case, the boundary condition may generate regions identified as singularities regions. In this study, we describe slit- shape transmittance curve whose diffraction field presented bifurcation effects and focusing regions know as caustics. The geometric shape of the transmittance curve allow us to study the structure diffraction fields, they are organized around focusing regions. We describe singularities that correspond to fold and cusped regions, which it is associating to the curvature of the transmittance curve. In the cusp catastrophe is generated the dislocations of the Pearcey diffraction pattern. The generation of singularities is studied by the propagation in free space.

8843-26, Session PMon

Creation of Flattop Light Field through Tightly Focusing of Cylindrical Vector Beams

Maojin Yun, Chenglong You, Mei Wang, Wei Lv, Wenxin Wang, Qingdao Univ. (China)

Recently, the particular polarization distributions of cylindrical vector beams have attracted great attention and quickly became the subject of extensive worldwide research due to their applications in lithography, optical storage, microscopy and optical trapping. In this paper, inhomogeneous status of polarization was obtained by designing the polarization-selective diffractive optical elements. With the optimization by custom-designed merit function and genetic algorithm, long focal depth and smaller focal spot is obtained by the numerical analysis. Meanwhile, 1D, 2D and 3D flat-top light field is designed and discussed. Finally, the property of various pattern cylindrical vector beams is studied. By adjusting the combination of different polarized beams, the optical bubbles and optical cages is obtained by high-NA lens.

8843-27, Session PMon

Optical tweezers formed by pure phase pupil filter

Maojin Yun, Wei Lv, Chenglong You, Qingdao Univ. (China); Mei Wang, Qingdao Univ (China)

Sharply focused light spot have attracted great attention and quickly became the subject of extensive worldwide research due to their applications in lithography, optical storage, microscopy, material processing, and optical trapping. Focusing properties of the radially polarized beam in high numerical aperture system with designed pure phase filter are analyzed in detail by using vector Debye diffraction theory. The simulation result shows that sharper focused light spot and flattop focusing can be obtained with the optimized pure phase filter. And the relation between the side lobes and the designed pure phase filter is also discussed. It is shown that the influence of the side lobes is smaller with the increased number of ring-zones of the pure phase filter.

8843-28, Session PMon

Learning algorithm convergence when utilizing a combined time-frequency representation as a basis

Attie Hendriks, CSIR National Laser Ctr. (South Africa) and Stellenbosch Univ. (South Africa); Hermann Uys, CSIR National Laser Ctr. (South Africa); Anton du Plessis, Christine Margarete Steenkamp, Stellenbosch Univ. (South Africa); Andre Smit, Lourens Rasmus Botha, CSIR National Laser Ctr. (South Africa)

Light is capable of directly manipulating and probing molecular dynamics at its most fundamental level. One versatile approach to influencing such dynamics exploits temporally shaped femtosecond laser pulses. Oftentimes the conditions necessary to induce a desired reaction cannot be determined theoretically a priori. However under certain circumstances these conditions or control mechanisms can be extracted experimentally through trial and error. This can be implemented systematically by using an evolutionary learning algorithm with closed loop feedback. Most frequently pulse shaping algorithms operate within either the time or frequency domain, however seldom both. The choice of basis influences the physical insight gained, as well as the time to convergence of the algorithm.

As an alternative to the Fourier domain, we make use of a combined time-frequency representation known as the von Neumann basis, observing temporal and spectral effects at the same time. We report on the experimental results obtained using the von Neumann basis by optimizing second harmonic generation in a non-linear crystal. We show experimentally that the von Neumann representation converges faster than the Fourier domain when compared to searches in the Fourier domain with the basis sets of the same size. We also report on theoretical results optimizing excitation of vibrational levels in molecular ensembles. Here once again the von Neumann representation converges faster that the Fourier domain.

This report shows that the von Neumann basis can be used as a viable alternative to the Fourier domain with improved convergence time and potentially deeper physical insight.

Conference 8844: Optical System Alignment, Tolerancing, and Verification VII

SPIE Optics+Photonics
Optical Engineering + App.

Sunday - Monday 25–26 August 2013

Part of Proceedings of SPIE Vol. 8844 Optical System Alignment, Tolerancing, and Verification VII

8844-1, Session 1

Optomechanical considerations for realistic tolerancing

Eric Herman, The Univ. of Arizona (United States); José Sasián, College of Optical Sciences, The Univ. of Arizona (United States); Richard N. Youngworth, Riyo LLC (United States)

Optical tolerancing simulation has improved such that the modeling of opto-mechanical accuracy can better predict end results. One refinement being proposed within this paper is monitor formal interference fits and to check lens elements within their mechanical housings. Without proper checks, simulations may become physically unrealizable and pessimistic, and result in lower simulated yields. This improved simulation method has been defined and demonstrated against with a system without barrel constraints showing the possible difference in yield results. Considerations of the opto-mechanical system will assist in controlling cost and provide more accurate simulation results.

8844-2, Session 1

Alignment of 4-mirror wide field corrector for the Hobby-Eberly Telescope *(Invited Paper)*

Chang Jin Oh, Eric H. Frater, Laura E. Coyle, Matthew B. Dubin, Andrew E. Lowman, Chunyu Zhao, James H. Burge, College of Optical Sciences, The Univ. of Arizona (United States)

The Hobby-Eberly Telescope (HET) Wide Field Corrector (WFC) is a four-mirror optical system which corrects for aberrations from the 10-m segmented spherical primary mirror. The WFC mirror alignments must meet particularly tight tolerances for the system to meet performance requirements. The system uses 1-m class highly aspheric mirrors, which precludes conventional alignment methods. For the WFC system alignment a "center reference fixture" has been used as the reference for each mirror's vertex and optical axis. The center reference fixtures have both a CGH and sphere mounted retroreflector (SMR) nests. The CGH is aligned to the mirror's optical axis to provide a reference for mirror decenter and tilt. The vertex of each mirror is registered to the SMR nests on the center reference fixtures using a laser tracker. The spacing between the mirror vertices is measured during the system alignment using these SMR nest locations to determine the vertex locations. In this paper we present the procedures and results from creating and characterizing these center reference fixtures. As a verification of our alignment methods we also present results from their application in the WFC system alignment.

8844-3, Session 1

Secondary color correction and tolerance sensitivity: how much can you get away with *(Invited Paper)*

John R. Rogers, Synopsys, Inc. (United States)

As many authors have documented, it is possible to correct secondary color without using special glasses, if there are substantial separations between lenses or groups that are chromatically uncorrected. The trick is to use the separations to "induce" secondary color by allowing the rays of different colors to separate from each other before being refracted by the group that follows. This approach works, but the use of separated and uncorrected groups that correct each other raises the question of tolerance sensitivity, because misalignments between the groups causes imperfect correction of the aberrations. It is generally good practice to correct aberrations within groups, rather than allow the groups to "cross-correct" each other. On the other hand, the use of special glass types to control secondary color directly is often either discouraged for cost reasons, or simply not allowed because of thermal shock sensitivity. Moreover, some optical systems (particularly projector applications) require extremely good secondary color correction – often to a small fraction of a pixel. The important question is how much secondary color can be induced before the increased tolerance sensitivity negates the advantage of the color correction. In this paper, we examine the as-designed and as-built performance of several sample systems that rely on separated groups for the correction of secondary color, and compare the performance to that of systems designed without regard to secondary color correction.

8844-4, Session 1

Gravity and extreme magnetism x-ray polarimeter instrument alignment

J. Allen Crane, NASA Goddard Space Flight Ctr. (United States); Mark Cascia, Cascia & Associates (United States); Keith M. Jahoda, Jean H. Swank, NASA Goddard Space Flight Ctr. (United States)

The NASA Gravity and Extreme Magnetism (GEMS) X-ray Polarimeter Instrument had a technically successful PDR but was not confirmed for implementation in 2012 due to budget concerns. The GEMS team is preparing to re-propose this mission, as the scientific objectives remain compelling and are not being addressed by any operating or approved missions. GEMS will allow astronomers to make a sensitive survey of the polarization of black hole, neutron star, and supernova X-ray sources, providing unique information on many astrophysical phenomena. GEMS instrument requires two mirrors to be positioned on a deployable boom 4.5 meters from twin Polarimeters with accuracy and stability such that the target X-Rays are focused in each Polarimeter. This paper will present an overview of the status of the instrument alignment effort and associated challenges. The paper will describe the alignment tools developed to assess alignment viability: Alignment & Pointing Budgets, STOP Analysis, and Monte Carlo Requirement Analysis. These tools steered refinement of the instrument primary interfaces and integration process, and appropriate apportionment of requirements to meet the overall observatory efficiency. The tools drove mirror interface design to limit thermal effects on the mirror focal length, and the addition of flexures to the mirror sunshields to correct a CTE mismatch stability concern. The paper will also discuss the metrology methodology and statistical solutions employed to overcome alignment challenges posed by the deployable boom. The alignment tools and methodologies employed have helped guide development of a viable design, and instrument integration and test process for GEMS.

8844-5, Session 2

Optical alignment of the Global Precipitation Measurements (GPM) star trackers

Samuel E. Hetherington, NASA Goddard Space Flight Ctr. (United States); Dean Osgood, Vicki Roberts, Joseph C. McMann, James E. Gill, Kyle McLean, NASA Goddard Space Flight Ctr. (United States) and QinetiQ North America (United States)

The optical alignment of the star trackers on the Global Precipitation Measurements (GPM) core spacecraft at NASA Goddard Space Flight Center (GSFC) was challenging due to the layout and structural design of the GPM Lower Bus Structure (LBS) in which the star trackers are mounted as well as the presence of the star tracker shades that blocked line-of-sight to the primary star tracker optical references. The initial solution was to negotiate minor changes in the original LBS design

to allow for the installation of a removable item of ground support equipment (GSE) that could be installed whenever measurements of the star tracker optical references were needed. However, this GSE could only be used to measure secondary optical reference cube faces not used by the star tracker vendor to obtain the relationship information and matrix transformations necessary to determine star tracker alignment. Unfortunately, due to unexpectedly large orthogonality errors between the measured adjacent cube faces and the lack of cube calibration data, we required a method that could be used to measure the same reference cube faces as originally measured by the vendor.

We describe an alternative technique to theodolite auto-collimation for measurement of an optical reference mirror pointing direction when normal incidence measurements are not possible. This technique was used to successfully align the GPM star trackers and has been used on a number of other NASA flight projects. We also discuss alignment theory as well as a GSFC developed theodolite data analysis package used to analyze angular metrology data.

8844-7, Session 2

Integration and alignment of ATLAS instrument engineering model components in Optical Development System Lab

Tyler C. Evans, John P. Lehan, SGT, Inc. (United States)

The Optical Development System Lab (ODSL) has matured from testing and aligning prototypes to testing engineering models that are representative of the flight components. Through this process many lessons have been learned that can be directly applied to flight integration and testing, helping drive down risk, cost, and schedule for the overall science instrument. The main ICESat-2 instrument is the Advanced Topographic Laser Altimeter System (ATLAS). It measures ice elevation by transmitting laser pulses, and collecting the reflection in a telescope. Because the round trip time is used to calculate distance, alignment between the outgoing transmitter beam and the incoming receiver beams are critical. An automated closed loop monitoring control system is currently being tested at the engineering model level to prove out implementation for the final spacecraft. To achieve an error of less than 2 micro-radians, an active deformable mirror was used to correct the lab wave front from the collimated “ground reflection” beam. The lab includes a focal plane assembly set up, a one meter diameter collimator optic, a 0.8 meter flight spare telescope for alignment, and the appropriate flight software to control the transmit beam path. By having a fully integrated system with prototypes and engineering units, lessons can be learned before flight designs are finalized.

8844-9, Session 2

High-power laser parabola focus modelling at the Central Laser Facility

Robert I. Heathcote, Robert J. Clarke, Trevor B. Winstone, Peta S. Foster, Science and Technology Facilities Council (United Kingdom)

For many years parabolic mirrors have been used as the primary focusing optics of short pulse high power lasers. Pushing the boundaries of the highest focused intensities requires not only increases in peak laser power but also exploring the limits of focal spot size. Modelling has been performed at the Central Laser Facility to evaluate the performance and tolerance of alignment of a variety of on and off axis parabolic mirrors and their limitations in correcting beam aberrations. Practical considerations such as debris shields and the mounting have also been assessed for their effects on the focal spots. Also modelling as an aid for practical alignment of parabolic mirrors to produce the tightest focal spots is presented.

8844-22, Session 2

Some effects of temperature gradients on the performance of imaging systems and their tolerances

Dmitry Reshidko, José Sasián, College of Optical Sciences, The Univ. of Arizona (United States)

A temperature change has the major effects in an optical system of changing the index of refraction and the geometry of the lens elements according to the coefficient of thermal expansion. These two effects induce first-order imaging changes and aberrations which may degrade performance of the optical system. We discuss the effects from a lens uniform temperature change, a temperature gradient from a uniform heat load across the lens, and a lens edge temperature change. We provide formulas to estimate and tolerance the optical effects from these temperature changes.

8844-11, Session 3

Alignment and testing of a telecentric zoom lens used for the Cygnus x-ray source

Robert M. Malone, Stuart A. Baker, Kristina K. Brown, Alden H. Curtis, David L. Esquibel, Daniel K. Frayer, Brent C. Frogget, James R. Garten, National Security Technologies, LLC (United States); Todd J. Haines, Los Alamos National Lab. (United States); Russell A. Howe, Joe A. Huerta, Morris I. Kaufman, National Security Technologies, LLC (United States); Nicholas S. P. King, Los Alamos National Lab. (United States); Stephen S. Lutz, Kevin D. McGillivray, Andrew S. Smith, Aric Tibbitts, National Security Technologies, LLC (United States)

Cygnus is a high-energy radiographic x-ray source. Three large zoom lenses have been assembled to collect images from large scintillators. A large elliptical pellicle (394 x 280 mm) deflects the scintillator light out of the x-ray path into an eleven-element zoom lens coupled to a CCD camera. The zoom lens and CCD must be as close as possible to the scintillator to maximize light collection. A telecentric lens design minimizes image blur from a volume source. To maximize the resolution of objects of different sizes, the scintillator and zoom lens are translated along the x-ray axis, and the zoom lens magnification changes. Zoom magnification is also changed when different-sized recording cameras are used (50 or 62 mm square format). The LYSO scintillator measures 200 x 200 mm and is 5 mm thick. The scintillator produces blue light peaking at 435 nm, so special lens materials are required. By swapping out one doublet and allowing all other lenses to be repositioned, the zoom lens can also use a CsI(Tl) scintillator that produces green light centered at 540 nm. All lenses have an anti-reflective coating for both wavelength bands. Two sets of doublets, the stop, the scintillator, and the CCD camera move during zoom operations. One doublet has x-y compensation. Alignment of the optical elements was accomplished using counter propagating laser beams and monitoring the retro-reflections and steering collections of laser spots. Each zoom lens uses 60 lb of glass inside the 340 lb mechanical structure and can be used in either vertical or horizontal orientation.

8844-12, Session 3

Double Zernike polynomials and its application in optical alignment

Ming-Sen Tsao, Chao-Wen Liang, National Central Univ. (Taiwan)

The Zernike polynomials has been widely used in optical testing and lens design due to its orthogonality, balanced aberration contribution and its connection with the Seidel aberration polynomials. The combination of

one of the Zernike polynomials of pupil coordinate and the other Zernike polynomials of field coordinate is a four dimensional polynomials that can be used to describe the full-field performance of the optical system. This polynomial is said as the double Zernike polynomials (DZP). The full field aberration of an optical system can be fully described by the double Zernike polynomial with the coefficients of each polynomial terms by least squares fitting of the four dimensional wavefront. The aberration behavior of the perturbed or misaligned optical system can also be observed effectively by looking into the difference of the DZP coefficients after the perturbation. In this research paper, we use the Gram-Schmidt orthogonalization process to generate an DZP polynomials that is not only orthogonal over circular pupil but also the rectangular field. The implemented numerical example is a three-mirror anastigmatic telescope with bi-lateral symmetry. Finally, we perturbs the system and evaluate the system with the DZP. The method to align the perturbed optical system with DZP is also discussed.

8844-13, Session 3

FTDT modeling of chip-to-chip waveguide coupling for optical quilt packaging

Tahsin Ahmed, Univ. of Notre Dame (United States); Thomas M. Butler, Univ. of Notre Dame (United States) and Cork Institute of Technology (Ireland); Aamir A. Khan, Univ. of Notre Dame (United States); Jason M. Kulick, Indiana Integrated Circuits, LLC (United States); Gary H. Bernstein, Anthony J. A. Hoffman, Scott S. Howard, Univ. of Notre Dame (United States)

We perform Finite-Difference Time-Domain (FTDT) simulations to explore feasibility of chip-to-chip waveguide coupling via Optical Quilt Packaging (OQP). OQP is a newly proposed scheme for wide-bandwidth, highly-efficient waveguide coupling and is suitable for direct optical interconnect between semiconductor optical sources, optical waveguides, and detectors via waveguides. This approach leverages advances in “Quilt Packaging®” (QP), an electronic packaging technique wherein contacts formed along the vertical faces are joined to form electrically-conductive and mechanically-stable chip-to-chip contacts. In OQP, waveguides of separate substrates are aligned with sub-micron accuracy by protruding lithographically-defined copper nodules on the side of a chip. With OQP, high efficiency chip-to-chip optical coupling can be achieved by aligning waveguides of separate chips with sub-micron accuracy and reducing chip-to-chip distance. We used MEEP, a free electromagnetic simulation software package, to investigate the feasibility of OQP by calculating the optical coupling efficiency. Transmission between a typical QCL ridge waveguide and a single-mode Ge-on-Si rib waveguide was calculated to exceed 65% when an interchip gap of 0.5 µm and to be no worse than 20% for a gap of less than 4 ?m. These results compare favorably to conventional off-chip coupling. To further increase the coupling efficiency and reduce sensitivity to alignment, we used a horn-shaped Ge-on-Si waveguide and found a 13% increase in coupling efficiency when the horn is 1.5 times wider than the wavelength and 2 times longer than the wavelength. Also when the horizontal misalignment increases, coupling efficiency of the horn-shaped waveguide decreases at a slower rate than a ridge waveguide.

8844-14, Session 3

Modified point diffraction interferometer to evaluate tolerances in the design of progressive addition lenses

Sara Chamadoira, Univ. de Santiago de Compostela (Spain) and INDO Lens Group (Spain); José Sasián, College of Optical Sciences, The Univ. of Arizona (United States); Eva Acosta, Univ. de Santiago de Compostela (Spain)

The primmary aim of this work is to show the principles, design and performance of a modifed point diffraction interferometer (PDI) to evaluate the local higher order aberrations of progressive addition lenses (PAL’s) in order to anylize the tolerances of the design of these ophthalmic components for a reasonable level of confort in the different users.

The main modification of the PDI is the increment of the size of the “point”, i.e., the size of the pinhole. From the required sizes for high accuracy inerferometry of about fractions of microns, to several microns in this tailored version. The increasement of the size of the pinhole allows an easier alignemnet of the interferometer at expenses of reducing the interference region as well as the accuracy. Nevertheless the first problem represents, in fact, and advantage for our purposes and the accuracy is enough for visual purposes: Aberrations can be measured with an accuracy of lambda/10 with this tailored point diffraction interferometer.

We will also present the analysis of high order aberrations in 6 different PAL’s in circular regions within the 4 most relevant regions of interest (ROI) of the lenses. Each ROI will be studied for radius ranging from 0.4 to 2.4mm. The designed interferometer also allows easily choosing the position and number of the ROI’s by only axial and transversal movements of the semitransparent plate containing the pinhole. The device is compact, robust and accurate, the operational principle is very simple and it provides directly the local high order aberrations without adding an additional part in the interferometer.

8844-15, Session 4

Discrepancies when analyzing and testing high-aperture lenses with pupil aberration

Joseph R. Mulley, Melles Griot (United States)

Lenses with high numerical apertures can be optimized and manufactured to produce diffraction-limited performance across an entire field-of-view while having significant pupil aberration. Understanding the functions of the lens in the application is important when designing, modeling, and testing the lens. Optimization is generally based on RMS wavefront error due to its speed. Most modern optical software correctly takes into account the need for chief-ray aiming but can still model such systems differently from one another, including the reporting of RMS values. These differences can affect the expected nominal performance, both on- and off-axis, and can therefore complicate technical discussion and have an effect on tolerancing. Polychromatic performance can be affected as well. How the lens is tested, for instance with an interferometer, can lead to further discrepancies between the modeled performance, actual system function, and the test data. These differences are explored in the case of a high NA objective lens. The reasons for these differences are examined.

8844-16, Session 4

Highly-accurate measurement of lens surface distances inside of optical assemblies for quality testing

Patrik Langehanenberg, Dennis Off, Bernd Lueerss, TRIOPTICS GmbH (Germany)

In the assembly of multi-component optical systems the precise positioning of every single lens element respectively lens surface is key to reach an optical performance that corresponds to the optical design. Here, in addition to lateral decentering of single elements – such as shift and tilt – the accurate positioning of the optical surfaces along the optical axis is an essential requirement.

In this contribution we present the highly accurate determination of lens center thicknesses and air gaps of optical assemblies in a non-contact manner. The measurement technique is based on time-domain optical coherence tomography. Here, a short coherent interferometer signal is recorded in a Michelson-type setup as a function of a variable optical delay in the reference arm. Whenever the variable optical path length matches the path length to a lens surface, a coherence peak occurs.

Thus, relative surface distances can be derived from the optical delay between two peaks. For a highly-accurate measurement a precise determination of the optical delay length with minimized Abbe-errors is required. Here, a precise long-coherent reference interferometer is superimposed to the short-coherent signal in the optical delay line. Both signals are recorded simultaneously; subsequently, the data is transferred to a PC system for the analysis.

With the presented technique lens thicknesses and air spacings of up to 800 mm can be measured with a resulting accuracy significantly below 1 µm. The obtained results can be used for the compensation of potential deviations/errors in the manufacturing process or for quality control using a pass/fail-evaluation.

8844-17, Session 4

A new approach for the verification of optical systems

Muhammad Umair Siddique, Vincent Aravantinos, Sofiene Tahar, Concordia Univ. (Canada)

Optical systems are increasingly used in microsystems, telecommunication, aerospace and laser industry. Due to the complexity and sensitivity of optical systems, their verification poses many challenges to engineers. Traditionally, the analysis of such systems has been carried out by paper-and-pencil based proofs and numerical computations. However, these techniques cannot provide accurate results due to the risk of human error and inherent approximations of numerical algorithms. In order to overcome these limitations, we propose to use theorem proving (i.e., a computer-based technique that allows to express mathematical expressions and reason about them by taking into account all the details of mathematical reasoning) as an alternative to computational and numerical approaches to improve optical system analysis in a comprehensive framework.

In particular, this paper provides a higher-order logic (a language used to express mathematical theories) formalization of geometrical optics in the HOL Light theorem prover. Based on the multivariate analysis library of HOL Light, we formalize the notion of light ray and optical system (by defining medium interfaces, mirrors, lenses, etc.), i.e., we express these notions mathematically in the software. This allows us to derive general theorems about the behavior of light in such optical systems. In order to demonstrate the practical effectiveness, we verify formally the stability of some resonators: Fabry Perot resonator with fiber rod lens and triangular resonator. The source code developed in this research is available for download and thus can be used by other researchers and engineers for the analysis of their optical systems.

8844-18, Session 4

The importance of optical methods and instruments in structural monitoring

Gheorghe M. Radulescu, Corina E. E. I. Radulescu, Technical Univ. of Cluj Napoca (Romania)

This paper addresses an extremely current field considering the conditions of building, with increasingly ambitious geometrical parameters, such constructions as television towers and smoke towers over 300 meters tall, civil construction over 800 meters tall, bridges over 20 km long, etc.

Structural monitoring is a component of any building's life, but in the case of the structures mentioned it is mandatory and very important in order to know the behavior "in situ" of a certain construction, the monitoring data practically validating the chosen design solution. Optical devices, i.e. theodolites, levels, GPS technologies, fiber optic sensors are essential in this activity. These instruments register how the structure responds to different loads/stress factors and allows the designer to check if the behavior meets the expectations set out in the design solution. The paper is a classification of these instruments and highlights, through examples, the position and importance thereof in SM and the fact that this application of optics is indeed crucial

The measurement and alignment for lens group in telescope

Ming Ming, Lv Tianyu, Jianli Wang, Changchun Institute of Optics, Fine Mechanics and Physics (China)

As a frequent part of optical systems, the lens group plays an important role in the large aperture optical system. But the lens group itself is not a good optical system, which could not be test directly after alignment. The paper gives a new method for measurement of the lens group after alignment. Firstly the single element should be measured, and then it is crucial that adds a concave spherical mirror with small aperture as the assistant element. It is not only important for measuring the wavefront of the lens group, but also significant for alignment analysis. The low order aberration such as coma, astigmatism and spherical aberration would be separated from aberration of manufacture. And according to the sensitivity of these aberrations, it is feasible that use the measurement process to iterative the alignment till these aberrations eliminated. About the new method, there are two typical aspects for example. One is that it uses the lens group as null lens for aspheric measurement; the other is that the lens group is used for aberration corrector, such as large telescope optical system. In aspect of aspheric test, the paper gives a measurement process of a concave elliptical mirror. The auto-collimation optical system for measurement includes interferometer, measured mirror and a small lens group that contains 2 spherical lenses. For the second aspect, the paper introduces a telescope with prime focus, which has wide field of view and large relative aperture. The optical system consists of primary mirror and a lens group corrector, the latter contains 4 elements, 3 spherical lenses and 1 elliptical lens. About the measurement after alignment of the two lens group, the paper analyzes the disadvantage during current measurement of the lens group, and then with adding one simple optical element as assistant. The paper measurement the both lens group, and All of the results of measurement are satisfying the requirement of design. The figure errors of spherical lenses are less than 0.1 fringe in the first step, and the figure errors of ellipsoid lens are less than $\lambda/30$ (RMS), the wavefront error at the third step is less than $\lambda/30$ (RMS). Finally, according to the result of measurement, the comparison of analyzed results and test results proves the reliability and precision of this method, which derives that the precision of measurement is better than 0.01λ. At last, directing with the measurement result, the optic quality of lens group after final alignment meet the design requirement.

8844-20, Session PMon

Development of a medium-size SWIR imaging telescope: integration, calibration, and MTF measurement

Ozgur Yilmaz, Ozgur Selimoglu, Fethi Türk, TÜBITAK UZAY (Turkey)

Imaging telescopes comprising of a reflective objective and an electronic detector are popular remote sensing devices for both earth observation and space exploration. Telescope is gathering the light and focuses it on the sensing element, a detector, and detector gives the image on its pixels. Since these devices require high signal to noise ratio, a large mirror at the optical aperture is very common.

Development of an imaging telescope with a large mirror, after the design stage, can be classified into two parts; integration and testing. Integration stage has also two steps; alignment of mirrors and placement of the detector. Testing part includes geometric and radiometric calibrations, and finally MTF measurement. MTF of an imaging system is the final and decisive parameter which shows that everything works well in the system. Currently all these steps are taken in a full-equipped laboratory with expensive devices such as collimators, interferometers and integrating spheres.

In this paper we investigate the methods of development and characterization of an imaging telescope using CMM (Coordinate

Measurement Machine) and scene-based techniques. Alignment of mirrors was realized by CMM . Detector was placed by the help of CMM and an image of a ruled outside building. Radiometric calibration was done with open-sky images. And finally MTF of the system was measured using stellar images. All these techniques do not require any auxiliary device except CMM. Scene-based calibration and MTF measurement can be repeated after the installation of telescope.

We found that MTF of our telescope is greater than %15 all along the detector at 20 lp/mm, which is the Nyquist frequency of 25 μm pixel size. This shows that alignment and focus adjustments work well enough in the telescope. These simple techniques can be used for the development and characterization of a medium-size and medium-resolution imaging telescopes.

8844-21, Session PMon

Optical phase retrieval method for the thermal deformation of space telescope's large primary mirror in the progress of alignment

Fan-jiao Tan, Harbin Institute of Technology (China)

Though it can protect optical system against outside temporary by sealing the major optical path, the primary, as the first collecting aperture, can not be protected by sealing, so which is effected firstly. So it is necessary to analysis the reflecting surface deformation of large primary mirror caused by surface temperature. If the primary mirror is effected by space environment temperature, the surface shape would occurs deformation, consequently the ideal reflecting wave front phase would be changed corresponding. So that the changing phase of practical wave front expresses the deformation variation of primary mirror surface. The papers rebuild the distorted wave front phase distribution by the way of analyzing the reflecting wave intensity. Effected by some temperature grade ,the deformation of large primary mirror surface is worse on the edge. The ideal point source in the entrance pupil is imaged by distorted surface, so the light intensity of the point source varies on the exit pupil. According to the intensity distribution and using least-square method, it can build the phase distribution of deformation wave front on the side of system exit pupil, thus can rebuild the mirror surface deformation by the phase information. From the analysis result, the maximum deformation rebuilding error is 0.033λ. So it can get that by the way of analyzing reflecting wave front optical intensity to get the phase distribution, it can rebuild the mirror deformation caused by surface thermal effect in high precision.

8845-1, Session 1

Ultrafast 3D imaging of isolated molecules with electron diffraction *(Invited Paper)*

Jie Yang, Christopher Hensley, Martin Centurion, Univ. of Nebraska-Lincoln (United States)

Imaging of isolated molecules with atomic resolution has been a longstanding scientific challenge. The majority of the known molecular structures have been determined using x-ray diffraction for crystallized molecules and Nuclear Magnetic Resonance (NMR) spectroscopy for molecules in solution. However, for isolated molecules there has been no method demonstrated to measure the three dimensional structure. Electron diffraction has been the main tool to determine the structure of molecules in the gas phase. In this method the diffraction pattern is compared with a calculated structure iteratively until a good match between experiment and theory is found. Diffraction patterns from randomly oriented molecules in the gas phase contain only one-dimensional information, and thus input from theoretical models is needed to recover the structure. We show that a three-dimensional image of a molecule can be reconstructed from electron diffraction patterns of laser-aligned molecules without any prior knowledge of the structure. The molecules are impulsively aligned with a femtosecond laser pulse and probed with femtosecond electron pulses in a field-free environment at the peak alignment. In this talk, I will show first results on simple molecules and how to generalize the method to more complex molecules. In addition, our setup can be used to investigate dynamics on ultrafast time scales with newly available femtosecond electron sources.

8845-2, Session 1

Ultrafast dynamic imaging of molecules with laser induced electron diffraction method *(Invited Paper)*

Chii-Dong Lin, Kansas State Univ. (United States); Junliang Xu, Lou DiMauro, Pierre Agostini, Cosmin Blaga, The Ohio State Univ. (United States)

When a molecule is placed in an intense few-cycle mid-infrared laser pulse, an electron which was released earlier in the pulse may be driven back by the laser field to recollide with the parent molecular ion. These returning electrons are analogous to a beam of laboratory prepared electrons used in the traditional electron diffraction experiment for probing the structure of molecules, but with the advantage that its pulse duration is of the order of a few femtoseconds. Based on theoretical analysis, we established that if the returning electrons have energies of the order of 100 eV or more, and if the electrons are backscattered by the target, then the resulting diffraction images can be analyzed using the same theory used in conventional electron diffraction method where electron beams have energies in the order of hundreds of keV's, but the scattering images are taken at forward angles. The advantage of laser induced electron diffraction method is that we can use few-femtosecond laser pulses that are already available. From the diffraction images generated by oxygen molecules using mid-infrared lasers, we showed that the bond length change of 0.1 Angstrom in five femtoseconds can be retrieved, thus for the first time establishing dynamic imaging with few femtosecond temporal resolution and sub-Angstrom spatial resolution.

8845-3, Session 1

Use of attosecond electron pulses to image electronic motion in atoms and molecules *(Invited Paper)*

Anthony F. Starace, Hua-Chieh Shao, Univ. of Nebraska-Lincoln (United States)

Ultrafast electron diffraction and microscopy have advanced significantly, enabling observation of transient structures in chemical reactions. The temporal widths of these electron pulses, however, range from fs to ps, which is inadequate for studying typical electronic motions in atoms and molecules. Recently, methods have been proposed for producing single-electron, attosecond pulses. The attosecond (as) temporal and sub-Å spatial resolutions of such ultrashort high energy electron pulses would enable four-dimensional (4D) study of electronic motion. We present here theoretical simulations demonstrating the potential of such attosecond electron pulses for 4D imaging of electronic motion in two prototypical systems: the H atom and the H2+ molecule. For the H atom, a few-fs laser pulse is proposed to excite a coherent superposition of two electronic states (the 3p and 4p levels of the H atom); for the H2+ molecule we consider a coherent superposition of two molecular states (the ?g1s and the ?u1s states). In both cases the charge distribution oscillates with the beat frequency of the coherently superposed states. For a 110 as electron pulse with energy of 10 keV we have investigated elastic differential scattering from these oscillating electronic states of H and H2+ [1] and inelastic scattering from the H atom target. Recently, we have also investigated ultrafast electron impact ionization (e,2e) processes for both the H and H2+ targets, which enable one to directly image the time-varying momentum distribution of the target electronic states.

8845-4, Session 1

Ultrabright low-repetition rate femtosecond electron sources: perspectives and challenges towards the study of structural dynamics in biological systems *(Invited Paper)*

Germán Sciaini, Univ. Hamburg (Germany)

One of the great dream experiments in Science is to directly observe atomic motions as they occur in chemical reactions and phase transformations. Femtosecond electron diffraction provided the first “light” of sufficient intensity to achieve this goal by attaining atomic resolution to structural changes on the relevant timescales. During my talk I will cover the technical progress that made this new level of acuity possible and give a survey of the new insights gained from an atomic level perspective of structural dynamics. Atomic level views of various structural processes are going to be discussed in light of the degree of directional bonding in the material - . Concepts such as non-thermal melting1,3 and ultrafast structural order parameters in low-dimensional systems are directly observable at the atomic level of inspection. For the delight of chemists, I will finalize my talk showing very recent results obtained for a labile organic crystal composed by light scattering centers. Here, we implemented a recently developed ultra-bright femtosecond electron source to obtain an atomically-resolved movie of the relevant molecular motions driving the photo-induced insulator-to-metal phase transition in the organic charge-transfer salt (EDO-TTF)2PF6. This study is the first in its kind and illustrates the potential of femtosecond electron sources to provide new insights into more complex structural phenomena relevant to chemistry and biology.

8845-5, Session 1

Photon-induced near field electron microscopy *(Invited Paper)*

Sang Tae Park, Ahmed H. Zewail, California Institute of Technology (United States)

Ultrafast electron microscopy in space and time domain utilizes a pulsed electron probe pulse to directly map structural dynamics of nanomaterial initiated by an optical pump pulse, in imaging, diffraction, spectroscopy, and their combinations. It has demonstrated its capability in the studies of phase transition, mechanical vibration, and chemical reaction. Moreover, electrons can directly interact with photons via near field component of light scattering by nanostructure, and either gain or lose light quanta discretely in energy. By energetically selecting those electrons that exchanged photon energies, we can map this photon-electron interaction, and is termed photon-induced near field electron microscopy (PINEM). Here, we give an account of the experimental observations and the theoretical understanding of PINEM. Experimentally, nanostructures such as sphere, cylinder, disk, and triangle have been investigated. Theoretically, time-dependent Schrödinger and Dirac equations for an electron under light are directly solved to obtain analytical solutions. The interaction probability is expressed by a mechanical work done to an electron by optical wave, which can be evaluated analytically by the near field components of the Rayleigh scattering for small spheres and thin cylinders, and numerically by the discrete dipole approximation for other geometries. Understanding of the phenomenon allows us to realize its potential applications.

8845-6, Session 1

Diffraction contrast as a sensitive indicator of femtosecond motion in ultrafast transmission electron microscopy

David J. Flannigan, Univ. of Minnesota (United States)

With ultrafast transmission electron microscopy (UTEM), access can be gained to the spatiotemporal scales required to directly visualize rapid, non-equilibrium structural dynamics of materials. This is achieved by operating a transmission electron microscope (TEM) in a stroboscopic pump-probe fashion by photoelectrically generating coherent, well-timed electron packets. These probe photoelectrons are accelerated down the TEM column where they travel through the specimen before reaching a standard CCD detector. A second laser pulse is used to excite (pump) the specimen in situ. Structural changes are visualized by varying the arrival time of the pump laser pulse relative to the probe electron packet at the specimen. Here, I will discuss how ultrafast nanoscale motions of crystalline materials can be visualized and precisely quantified using diffraction contrast imaging in UTEM. Because diffraction contrast sensitively depends upon both crystal lattice orientation as well as incoming electron wavevector, minor spatial/directional variations in either will produce dynamic and often complex patterns in real-space images. This is because sections of the crystalline material that satisfy the Laue conditions may be heterogeneously distributed such that electron scattering vectors vary over nanoscale regions. Thus, minor changes in either crystal grain orientation, as occurs during specimen tilting, warping, or anisotropic expansion, or in the electron wavevector result in dramatic changes in the observed diffraction contrast. In this way, dynamic contrast patterns observed in UTEM images can be used as highly sensitive indicators of ultrafast specimen motion. Further, these motions can be spatiotemporally mapped such that direction and amplitude can be determined.

8845-7, Session 2

Sum-frequency-generation (SFG) vibration spectroscopy study of crystalline cellulose in biomass *(Invited Paper)*

Seong H. Kim, The Pennsylvania State Univ. (United States)

The crystallographic information of the unit cell for the purified cellulose I-alpha and I-beta crystals provided foundations for understanding molecular interactions and packing between cellulose chains. However, little is known about how crystalline cellulose is assembled in intact plant cell walls, bacterial pellicles, and animal tissues. This question could be addressed by sum-frequency-generation (SFG) vibration spectroscopy [A. L. Barnette, et al. Biomacromolecules2011, 12, 2434-2439], which can selectively detect hierarchical ordering of crystalline cellulose in biomass without spectral interference from non-cellulosic components. This talk will address the structural interpretation and quantitative analysis of SFG signals from crystalline cellulose in various cellulose-producing organisms that have not been treated for isolation of cellulose. The SFG spectra of cellulose samples from different species revealed drastic differences in the relative distribution of SFG peaks, which cannot be explained with the structural information obtained from the x-ray diffraction (XRD) and infrared (IR) analyses of the same samples.

8845-8, Session 2

Probing ferroelectrics using optical second harmonic generation microscopy *(Invited Paper)*

Venkatraman Gopalan, The Pennsylvania State Univ. (United States)

Nonlinear Optics is emerging as a powerful imaging modality in materials science as well as life sciences. In this talk, I will present probing polar materials using confocal second harmonic generation microscopy (SHG). New ferroelectric phases with enhanced properties are discovered in classic ferroelectrics such as BaTiO3 and KNbO3 that were discovered over 60 years ago. New polar phenomena are discovered even in nominally nonpolar materials such as CaTiO3. Theoretical modeling of the SHG polarimetry results provide information about the point group symmetry and orientation of the polar domains.

8845-9, Session 2

Studies of hydrophobic organic molecules at water interfaces using phase-sensitive sum frequency vibrational spectroscopy *(Invited Paper)*

Chuanshan Tian, Fudan Univ. (China)

Hydrophobic organic molecules, because of the nature of their “hydrophobicity”, at a water interface had been supposed to have a little effect on water structure. Surprisingly, strong ion adsorption, such as OH-, Cl-, was found at (hydrocarbon) hydrophobic molecule/water interface, which sets up a surface field near the interface thus causing drastic reorientation of water molecules near the interface [1]. We have used phase-sensitive sum frequency vibrational spectroscopy (PS-SFVS) to probe the effects of solvated ions on the structure of hydrophobic molecules/water interfacial systems, including octadecyltrichlorosilane (OTS), Hexane, polyethylene, etc. In probing the interfacial water structure with SFVS, care was taken to make sure that the bulk contribution of water is negligible. Significant interactions between hydrophobic chains and hydroxyl ions are revealed. By varying the ion concentration in the bulk water, the adsorption isotherm was measured. The result shows that even the neat water/hydrophobic molecules interface is not neutral, but charged with hydroxyl ions (OH-). The possible mechanism of ion adsorption at the hydrophobic interfaces will be discussed.

8845-11, Session 3

Nanophotonics for information processing *(Invited Paper)*

Yeshaiahu Fainman, Univ. of California, San Diego (United States)

Various future system applications that involve photonic technology rely on our ability to integrate it on a chip to augment and/or interact with other signals (e.g., electrical, chemical, biomedical, etc.). For example, future computing and communication systems will need integration of photonic circuits with electronics and thus require miniaturization of photonic materials, devices and subsystems. Another example, involves integration of microfluidics with nanophotonics, where former is used for particle manipulation, preparation and delivery, and the latter in a large size array form parallel detection of numerous biomedical reactions useful for healthcare applications. To advance the nanophotonics technology we established design, fabrication and testing tools. The design tools need to incorporate not only the electromagnetic equations, but also the material and quantum physics equations to include near field interactions. These designs are integrated with device fabrication and characterization to validate the device concepts and optimize their performance. Our research work emphasizes the construction of passive (e.g., engineered composite metamaterials, filters, etc.) and active (e.g., nanolasers) components on-chip, with the same lithographic tools as electronics. In this talk, we discuss some of the passive metamaterials and devices that recently have been demonstrated in our lab. These include our most recent results on monolithically integrated short pulse compressor utilized with SOI material platform and design, fabrication and testing of nanolasers constructed using metal-dielectric-semiconductor resonators confined in all three dimensions.

8845-12, Session 3

STED optical nanoscopy with organic and inorganic dyes *(Invited Paper)*

Peng Xi, Peking Univ. (China)

The conventional microscopy can only yield optical resolution approaching Abbe diffraction limit of ~200 nm. This is still larger than many subcellular structures, which are too small to be resolved in detail. These limitations have driven the development of super-resolution optical imaging methodologies over the past decade.

In stimulated emission depletion (STED) microscopy, the excitation focus is overlapped by an intense doughnut-shaped spot to instantly de-excite markers from their fluorescent state to the ground state by stimulated emission process. This effectively eliminates the periphery of the fluorescent Point Spread Function (PSF), resulting in a narrower focal region, or super-resolution. Yet, since the organic dye is prone to the ON-OFF process of STED, they suffer from photobleaching severely in STED nanoscopy. One alternative is to seek the approach of inorganic dye.

In this work, we present the application of STED nanoscopy in subcellular organelle imaging. With two excitation lasers of 532 nm and 635 nm, and the depletion laser of 760 nm, dual-color STED has been used in the study of colocalization of human respiratory syncytial virus. Fluorescent nano-diamond has been imaged as a photostable inorganic dye. With novel upconversion nanoparticles as fluorescent labels, we have achieved super-resolution with power levels 2 orders of magnitude than conventional STED nanoscopy with organic dyes.

8845-13, Session 3

Self-assembled nano-materials for nonlinear fiber optics and tunable plasmonics *(Invited Paper)*

Yong Xu, Islam Ashry, Ishac Kandas, Hans D. Robinson, James R. Heflin, Virginia Polytechnic Institute and State Univ. (United States)

Since silica is an amorphous material with full inversion symmetry, silica-based microstructures cannot possess significant second-order nonlinearity. We recently developed a method that can potentially overcome this deficiency by coating a silica fiber taper with layers of radially aligned nonlinear molecules. The coating process can be accomplished through layer-by-layer self-assembly, where the alignment of the nonlinear molecules is maintained through electrostatic interaction. As a result, the nonlinear fiber structures are thermodynamically stable and can generate significant second-order nonlinear responses despite their full rotational symmetry. This prediction has been experimentally confirmed through SHG measurements. To further enhance the overall second order nonlinearity, we have developed a laser ablation based approach that can generate second-order nonlinearity that is spatially periodic along the fiber taper. Our preliminary experiments suggest that SHG intensity can be enhanced by such quasi-phase matching configurations.

A similar approach has been developed for constructing tunable plasmonic systems. As a proof-of-concept study, we assembled swellable polymer films over a planar Au substrate through layer-by-layer assembly and covered the swellable polymer with a monolayer of quantum dots. After immersing the swellable plasmonic structure in solution and adjusting its pH value, we used an atomic force microscope and fluorescence lifetime measurements to demonstrate that the thickness of the swellable polymers can be modified by as much as 300%. Through fluorescence lifetime studies, we also confirmed that the plasmonic resonance can be significantly changed by the swellable polymers.

8845-14, Session 3

Study of electronic properties of epitaxial graphene using coherent controlled photocurrent injection *(Invited Paper)*

Dong Sun, Peking Univ. (China)

In this talk, we report generation of ballistic electric currents in unbiased epitaxial graphene at 300 K via quantum interference between phase-controlled cross-polarized fundamental and second harmonic 220 fs pulses. The transient currents are detected via the emitted terahertz radiation. Based on this coherent controlled photocurrent injection method, we have studied various electronic properties of epitaxial graphene.

In one experiment, we have measured the third-order nonlinear tensor in epitaxial graphene as a novel approach to probe interlayer electronic coupling, by studying THz emission from coherently controlled photocurrents as a function of the optical pump and THz beam polarizations. We find that the polarization dependence of the coherently controlled THz emission expected from perfectly uncoupled layers, i.e. a single graphene sheet, is not observed. A model calculation, treating the interlayer coupling as bilayer coupling with variable strength, qualitatively reproduces the polarization angular dependence, providing evidence for coupling.

In another experiment, we use coherent control with ultrashort optical pulses to photoinject a current and detect the terahertz (THz) radiation emitted by the resulting current surge. We pre-inject a background of hot carriers using a separate pump pulse, with a variable delay between the pump and current-injection pulses. We find the effect of the hot carrier background is to reduce the current and hence the emitted THz radiation. The current damping is determined simply by the density (or temperature) of the thermal carriers. The results indicate that hot carriers are effective in damping the current, and are expected to be important for understanding the operation of high-speed graphene electronic devices.

8845-15, Session 4

Correction of blurred image by exploiting phase conjugation based on single second-order nonlinear parametric processes *(Invited Paper)*

Yujie J. Ding, Lehigh Univ. (United States)

During this presentation, we will summary our recent progress made by my group on correction of blurred images caused by atmospheric turbulence by using phase-conjugated beams generated by difference-frequency generation in stacked KTP plates. We have demonstrated that when the incoming beam is phase-distorted the phase-conjugated beam can be used to clean up the distortion. We have further demonstrated that image quality can be restored after the phase distortion. This represents a novel approach for image restoration based on nonlinear optics. The image correction is insensitive to the polarization of the incoming beam. Our approach is instantaneous. Furthermore, the pump power as low as 1 mW is required to reach the nonlinear power reflection coefficient of 100%. Therefore, it is ideal for us to correct the blurred images caused by atmospheric turbulence using our approach.

8845-16, Session 4

Wave mixing of intense terahertz fields and optical pulses in solids: parametric interactions, nonlinear terahertz imaging, and 3D-mapping *(Invited Paper)*

Matteo Clerici, Institut National de la Recherche Scientifique (Canada) and Heriot-Watt Univ. (United Kingdom); Daniele Faccio, Heriot-Watt Univ. (United Kingdom); Lucia Caspani, Institut National de la Recherche Scientifique (Canada); Eleonora Rubino, Univ. degli Studi dell'Insubria (Italy); Marco Peccianti, Istituto dei Sistemi Complessi (Italy); Luca Razzari, Tsuneyuki Ozaki, Roberto Morandotti, Institut National de la Recherche Scientifique (Canada)

Developing novel and high-sensitivity techniques for imaging of terahertz (THz) fields is essential for the increasingly diffused diagnostic applications of such a long wavelength radiation. Although recent technological progresses resulted in more accessible and performing THz space-resolved detectors, there is still a large gap with the silicon-based detectors employed for measuring visible light in terms e.g. of signal-to-noise ratio and costs.

We theoretically and experimentally investigated the four-wave mixing of broadband THz pulses –generated by laser-induced plasma with peak electric fields in the order of few MV/cm and 90 fs duration (full-width at half maximum)– with optical pulses at ? 790 nm carrier wavelength, delivered by a Ti:Sapphire laser, as a mean for THz detection and imaging. For our investigations we employed a diamond crystal as a nonlinear medium, chosen due to its large transmission bandwidth, covering both the UV-VIS as well as the Far-Infrared and THz range.

We show that two parametric processes occur, namely sum- and difference-frequency generation, and that such processes are up-frequency shifting mechanisms able to map the spatial properties of a THz beam into the visible spectrum. Hence, THz beam profiling and imaging can be readily performed by means of a simple (and economic) CCD camera. Furthermore, we show that, among the possible interaction geometries, phase matching is achieved for THz pulses counter propagating with the optical probe beams, which results in a novel and intriguing THz detection scheme. Finally, we will show how full three-dimensional mapping of unknown THz pulses can be performed.

8845-17, Session 4

Applications of swept-fiber-laser-based nonlinear (CARS, SRS) or linear (mid-infrared) molecular spectroscopy system *(Invited Paper)*

Alain Villeneuve Jr., Youngjae Kim, Alexandre Dupuis, Rajeev Yadav, André Archambault, Guido Pena, Mathieu Giguère, Bryan Burgoyne, Joseph Salhany, Genia Photonics Inc. (Canada)

Genia has developed a swept-laser-based nonlinear spectroscopy system using robust and agile all-fiber-based synchronized programmable laser (SL). The system includes a rapidly tunable Ytterbium-Doped-Fiber-based picosecond Programmable laser (PL) suitable for imaging techniques such as Optical Coherence Tomography (OCT) and Second Harmonic Generation (SHG) and a fixed wavelength Master-Oscillator Power Amplifier (MOPA). The MOPA is a fixed wavelength frequency doubled Erbium-Doped-Fiber-based Master-Oscillator Power Amplifier operating at 767.5 nm and/or 792.5 nm. The PL can be wavelength-tuned within the 1020-1080 nm at speed suitable for real time OCT and for Coherent Anti-Stokes Raman Scattering (CARS) and Stimulated Raman Scattering (SRS) spectroscopy in the high wavenumber region (2800-3350 cm-1). Another PL tunable around 850 nm is also under development to address the fingerprint region (800-1660 cm-1). The lasers for the mid-IR linear spectroscopy system mix either 1020-1080 nm, 1530-1605 or 1900-2030 nm to achieve those regions.

The pulse width can be optimized for the long coherence length required for OCT or compressed to a few ps for nonlinear imaging such as SHG. The pulse for CARS/SRS are maintain at 20 ps for the nonlinear spectroscopy to avoid any issues with timing jitter between the two lasers. The difference in energy and the synchronization can be maintained at more than 50 000 wavelengths per second allowing for spectrum to be acquired in about 1 ms.

The system also includes two detectors, a data acquisition card and a computer to control the laser and to display the acquired spectrum. The applications of the system to linear, in the mid-IR, and nonlinear, in the near infrared, molecular spectroscopy will be shown.

8845-18, Session 4

Spectrography for 3D analysis from a single spectral view *(Invited Paper)*

Yan Xi, Jun Zhao, Shanghai Jiao Tong Univ. (China); Xiaojing Huang, Brookhaven National Lab. (United States); Hengyong Yu, Wake Forest Univ. School of Medicine (United States); Yuxin Wang, Argonne National Lab. (United States); Ge Wang, Rensselaer Polytechnic Institute (United States)

Coherent diffraction imaging (CDI) is a lens-less imaging technique for studying non-crystalline samples. Without the limitations of optical elements in lens-based imaging systems, spatial resolution of CDI can be of nanometer-scale. With the great power of x-ray free electron laser (FEL), femtosecond-scale temporal resolution can be achieved, which is critical for uncovering bio-molecular interactions and other processes. However, the huge radiation dose of FEL will destroy a sample with a single exposure, which makes it difficult to perform conventional 3D imaging which demands measurements around the sample. To have 3D analysis from only one view, we proposed a spectral imaging scheme, referred to spectrography. Instead of determining the complete 3D structure of the sample, an initial goal of spectrography is to retrieve those projections of the sample that are not much different from the x-ray propagation direction. In this paper, we extend the spectrography method to image complex samples. Utilizing a weighted difference map algorithm, specific Fourier planes are estimated through the origin of the 3D Fourier space and the measured Ewald sphere. Then, complex x-ray wave fields are reconstructed at different viewing angles. The computed projections provide critical clues on features of interest inside the sample. To demonstrate our proposed method, both numerical and physical experiments were performed. The results suggest that spectrography is practical and effective for 3D analysis of an object from a single spectral view.

8845-19, Session 4

CMOS: compressive multi-heterodyne optical spectroscopy

Nikhil Mehta, The Pennsylvania State Univ. (United States); Jingbiao Chen, Zhigang Zhang, Peking Univ. (China); Zhiwen Liu, The Pennsylvania State Univ. (United States)

High resolution optical spectroscopy facilitates research in fundamental sciences such as analysis of energy levels in atomic and molecular structures, Doppler shift measurements, evaluation and monitoring of fundamental constants; and enables applications such as molecular fingerprinting of gas molecules and identification of drugs and biological species. Recent advances in generation and control of octave spanning laser frequency combs have opened new opportunities for ultra-high resolution optical spectroscopy employing multi-heterodyne scheme. Existing multi-heterodyne techniques based on combining a pair of frequency combs which have slightly different mode spacing yield a discrete spectrum sampled at the comb modes and hence utilize 'dense' combs for improving the frequency sampling. In order to provide continuous frequency coverage across the entire multi-THz optical band without increasing the acquisition time, we propose a general formulation for compressive multi-heterodyne spectroscopy using dynamically encoded frequency comb to map multiplexed optical spectrum to the RF domain. We present proof-of-concept numerical simulations using iterative algorithms based on compressive sensing to take advantage of sparsity inherent in typical optical spectra of interest to reduce the number of RF measurements. We demonstrate the retrieval of a hypothetical 20THz wide optical spectrum using a hypothetical frequency comb with 50GHz mode spacing by using fewer than 25% RF measurements as compared to the number of comb modes. Our results are consistent with the theoretically expected reduction in the number of measurements for successful retrieval based on sparsity-constrained inversion. Our technique applies equally well for both incoherent and coherent (both amplitude and phase) spectrum measurement.

8845-20, Session 5

Using single molecule-imaging method to resolve functional stoichiometry of ion channel *(Invited Paper)*

Liangyi Chen, Peking Univ. (China)

Two proteins, STIM1 in the endoplasmic reticulum and Orai1 in the plasma membrane are required for the activation of calcium release-activated calcium (CRAC) channels at the cell surface. How these proteins interact to assemble functional CRAC channels has remained uncertain. Here we determine how many Orai1 and STIM1 molecules are required to form a functional CRAC channel. We engineered several genetically expressed fluorescent Orai1 tandem multimers and a fluorescent, constitutively active STIM1 mutant. The tandem multimers assembled into CRAC channels as seen by rectifying inward currents and by cytoplasmic calcium elevations. CRAC channels were visualized as fluorescent puncta in total internal reflection microscopy. With single-molecule imaging techniques, it was possible to observe photo-bleaching of individual fluorophores and to count the steps of bleaching as a measure of the stoichiometry of each CRAC channel complex. We conclude that the subunit stoichiometry in an active CRAC channel is four Orai1 molecules and two STIM1 molecules. Fluorescence resonance energy transfer experiments also showed that four Orai1 subunits form the assembled channel. From the fluorescence intensity of single fluorophores, we could estimate that our transfected HEK293 cells had almost 400,000 CRAC channels and that when intracellular Ca^{2+} stores were depleted, the channels clustered in aggregates containing about 1,300 channels, amplifying the local Ca^{2+} entry.

8845-21, Session 5

Biological dynamics and mechanisms studied by ultrafast spectroscopy *(Invited Paper)*

Dongping Zhong, The Ohio State Univ. (United States)

Biological function is a complex process and the understanding of its molecular mechanism is essential for practical applications such as in drug design and gene therapy. Here, we present our recent studies of an important biological system, repair of sun-damaged DNA by photoenzyme photolyase to prevent the potential skin cancer. With femtosecond spectroscopy and molecular biology methods, we have mapped out the entire evolution of repair by following the dynamics from the reactants, to intermediates to final products with a series of elementary reactions including ultrafast cyclic electron transfer and chemical bond breaking and making. These biological dynamics occur ultrafast on the picosecond time scales and are in synergy to maximize repair quantum efficiency. The results are significant and reveal the molecular mechanism and repair photocycle at local atomic scale and provide the molecualr basis for the future medical application.

8845-22, Session 5

Bond-selective imaging: a new window into the unseen world *(Invited Paper)*

Ji-Xin Cheng, Purdue Univ. (United States)

Label-free spectroscopic imaging using inherent chemical bond vibration signals as contrast opens a new window for watching biomolecules and nanomaterials inside living cells and human body. I will present our most recent advances in both development and applications of spectroscopic imaging platforms, including deep tissue imaging by listening to harmonic molecular vibration, study of lipid metabolism in cancer by coherent Raman microscopy, and super-resolution imaging of nanomaterials by transient absorption microscopy. Potentially transformative impacts of these projects will be illustrated.

8845-23, Session 5

Ultrafast optical imaging of microfluidic-scale physiology: opportunities and challenges *(Invited Paper)*

Michael A. Choma M.D., Yale School of Medicine (United States)

Many pediatric diseases are poorly understood, in part because they involve processes that occur at small, microscopic scales. In addition, the causes often involve small motions and fluid flows. For example, an early embryonic heart has a diameter of about 100 micrometers, which is about the diameter of a human hair. The cilia that move mucus out of our airways are even smaller- about 10 micrometers long. In order to better study pediatric disease at such small scales, we develop innovative optical imaging methods to visualize and quantify disease at these microscopic scales. I will discuss (a) the relevant temporal and spatial resolution requirements needed to quantify microfluidic-scale physiology, (b) our ongoing work at the interface of biomedical optics and microfluidic-scale physiology, and (c) the potential clinical impact of ultrafast imaging in microfluidic-scale physiology.

8845-24, Session 5

Highly quantitative label-free three-dimensional single cell imaging *(Invited Paper)*

YanYi Huang, Peking Univ. (China)

We present an optofluidic platform to perform the highly quantitative label-free measurement of single cells using stimulated Raman scattering (SRS) microscopy. Through integration with a microfluidic device that consists of an array of parallel culture chambers, we accurately control the microenvironment of every single cell and observe the cell's response to the environmental changes. SRS microscopy provides a label-free modality to observe the dynamical changes at the sub-cellular level, with the intrinsic three-dimensional sectioning ability. We use this system to monitor lipid metabolism and digitize the lipid droplet distributions and morphology, showing the great potential to study the details of lipogenesis and lipid-associate biological processes.

8845-25, Session 5

On chip optofluidic spectroscopy for biomedical applications *(Invited Paper)*

Zhenyu Li, The George Washington Univ. (United States)

Optical spectrometers have been widely used in biomedical applications such as DNA/RNA quantification, immunoassays and spectral imaging. Recent research on lab-on-a-chip systems has generated considerable interests in miniaturizing optical spectrometers/spectrographs integrated with microfluidic functions. However traditional microfabrication methods and solid state materials present significent challenges in fabricating microfluidics-compatible spectrometer systems. In this paper, I will discuss our efforts of implenting on-chip spectrographs using liquid metallic optofluidic components such as gratings, mirrors and pinholes.

8845-26, Session 5

Raman spectroscopy and optical coherence tomography for skin cancer study

Ivan A. Bratchenko, Valeriy P. Zakharov, Oleg O. Myakinin, Dmitry V. Kornilin, Dmitry N. Artemyev, Samara State Aerospace Univ. (Russian Federation); Alexander A. Moryatov, Sergey V. Kozlov, Samara Regional Clinical Oncological Dispensary (Russian Federation)

Nowadays medical staff notes an increase number of different skin lesions appearing including benign and cancerous tumors. Optimal approach of these disease treatments requires precise determination of invasion borders in healthy skin and noninvasive disease specificity estimation. This requirement may be satisfied by using optical techniques. In this study we demonstrate joint usage of optical coherence tomography (OCT) and Raman spectroscopy (RS) for in vivo and ex vivo skin tumors diagnosis. OCT setup was performed on the basis of a broadband superluminescent laser diode (840 ± 25nm) at the source end, Michelson interferometer with 50/50 split ratio to the sample and reference arms, spectrometer with diffraction grating (1200 gr/mm) and CCD line scan camera (2048 pix, 29.3 kHz) at the detection end. OCT system allowed real-time obtaining of healthy skin and pathologies 3D images. Herewith OCT image resolution was 6 - 8 micrometers that let one accurately determine the invasion area and respectively a resection zone. RS system contained Shamrock sr-303i spectrometer with DV420A-OE digital camera, RPB785 RS probe and LuxxMaster Raman Boxx laser (785nm, 200 - 300 mW). Raman spectrums from different tissues: melanoma, basal call carcinoma, pigment nevi, keratosis, normal skin, were used to identify the main chemical components of formations. Subsequent allocation of formations characteristics based on the Raman peaks intensities was performed. It was found that different skin formations have unique composition of intensities related to the lipid-specific and amide I proteins bands peaks near 1270, 1310, 1459 and 1657 cm-1. Analysis of peaks features observed in the Raman spectrum resulted in the identification criteria for specificity determination of tumors in the healthy skin.

8845-27, Session 6

Early excitation dynamics in conjugated polymers studied by two-dimensional Fourier transform spectroscopy *(Invited Paper)*

Kenan Gundogdu, Cong Mai, North Carolina State Univ. (United States)

Conjugated polymers and their hybrids with fullerenes have tremendous potential for use in low-cost, flexible, light weight opto-electronic applications and can be synthesized and processed to exhibit a variety of electronic behavior from metal-like to insulator. Characterization of primary excitations and their dynamics in pi-conjugated polymers has been an active research area for the last two decades. Yet many controversial views persist regarding the nature of initial optical excitations, as there are gaps in understanding of critical fundamental aspects of their transport, relaxation, and charge separation kinetics. As a result, applications and use of semi-conducting polymers are progressing largely by heuristic approaches. In this work, by using novel two-dimensional Fourier transform spectroscopy (2D FTS) , we provide new fundamental insight on optical processes in polymer. In contrast to the commonly accepted exciton picture, we observed that initially excited electrons and holes exhibit uncorrelated dynamics. While the electrons are static in a rigid environment, the holes are highly diffusive. These results suggest, we have to reconsider common views regarding the early dynamics in polymers.

8845-28, Session 6

Polarization study of all-optical magnetic recording in ferrimagnets

Ivaylo Ivanov, Xiangping Li, Philip Dolan, Swinburne Univ. of Technology (Australia); Yongbing Xu, Jing Wu, The Univ. of York (United Kingdom); Min Gu, Swinburne Univ. of Technology (Australia)

Owing to the ultrafast switching, opto-magnetic recording by a femtosecond pulsed laser beam is of great importance for the next generation of data storage. The tightly focused laser pulse allows data recording to be confined to a diffraction-limited region, offering tremendous potential for high density data storage. It has been demonstrated that circularly polarized light can act as an effective magnetic field through the inverse Faraday effect allowing optical writing of magnetic memory. Recently, it was found that the laser heating itself can also introduce the magnetization reversal, without any dependence on the polarization of the laser beam. The full nature of the dependence of opto-magnetic recording on the polarization of the writing beam is yet to be determined, but is necessary to completely understand the switching mechanism. In this paper, we present a systematic study of optically induced magnetization reversal in TbFeCo films by different polarization states of the femtosecond pulses. The experiments were conducted with single femtosecond pulses at a wavelength of 800 nm. The laser beam was focused with an objective onto a TbFeCo film with a thickness of 20 nm. Magnetization reversal was detected on a charge coupled device with a home-built polarizing microscope. In addition, a theoretical model considering electron heating by the laser pulse, followed by a thermal exchange between electrons and lattice has been developed. The obtained experimental dependencies were explained taking into account this effect and the role of the laser polarization in the heat transfer and magnetization reversal. Two power ranges corresponding to the inverse Faraday effect and laser-heating induced magnetic reversal, respectively, were identified.

8845-29, Session 6

Stable time-domain spectroscopy of femtosecond thermal-infrared pulses using a carrier-envelope-phase locked system

Sheng Liu, Thomas S. Mahony, Daniel A. Bender, Michael B. Sinclair, Igal Brener, Sandia National Labs. (United States)

We build a novel thermal-IR time domain spectroscopy system based on a triple-output near-infrared ultrafast fiber laser, phase-l ocked difference frequency generation (DFG) and phase-matched electro-optic sampling (EOS) that can be used to obtain the full complex electric field of tunable IR pulses. Thermal IR pulses are generated by difference frequency mixing of two pulse trains in a GaSe crystal. Due to the nature of DFG, an unstable carrier to envelope phase (CEP) can occur when the optical path difference between the two generating pulses drifts. To overcome this instability, we phase-lock the CEP of the IR pulse by using near-IR light reflected off the generation GaSe with a piezo controlled delay feedback loop. We fully studied the dependence of the amplitude and shape of the detected IR waveforms on the thickness of GaSe crystals used in DFG and EOS. This is done by varying the phase matching angles of the EOS crystal while fixing the DFG crystal which emits IR pulses centered at ?~9.6 µm. We observe optimum (shape and amplitude) electric field transient when a 500 µm and a 250 µm thickness GaSe crystals are used for generation and detection, respectively.

This work was performed, at the Center for Integrated Nanotechnologies, a U.S. Department of Energy, Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000. #158883

8845-30, Session 6

Ultrafast spectroscopy of hot electron and hole dynamics in GaP

Christopher M. Collier, Brandon Born, Xian Jin, Jonathan F. Holzman, UBC Okanagan (Canada)

Wide-bandgap semiconductors are appealing materials for photoconductive applications with large photon energies and high intensities. GaP is an excellent example of this and has received a recent resurgence in interest for applications such as terahertz (THz) generation, due to its excellent epitaxial growth properties and high optical phonon resonances (above 11 THz). Recently, Dietze et al. [Dietze, Opt. Lett., 2012] have, for example, made use of multiphoton nonlinearities in GaP for dynamic phase-tuning and efficient THz generation. Hot phonons are proposed as the nonlinear phase-tuning mechanism of GaP, although there is little understanding in the literature on the underlying ultrafast relaxation processes.

Given the interest in GaP, and the scarcity of knowledge on its ultrafast response, this work analyzes the femtosecond and picosecond carrier dynamics of GaP under intense photoexcitation. It is found that the dynamics are initially dominated by hot electron scattering to the X sidevalley from the central Gamma valley. Respective time constants of 800 fs and 4 ps are observed for transitions to the X7 and X6 valleys. A subsequent pump-fluence-dependent relaxation is observed over 30 to 52 ps timescales as pump fluence is increased. The prolonged energy relaxation is ascribed to impeded phonon decay in the X6 valley. Above and below a transition fluence value, distinct thermalization rate trends are observed. Experimental and theoretical results are shown to provide evidence for a hot phonon bottleneck at the high excitation fluences. The implications of these ultrafast carrier dynamics are discussed for emerging GaP applications.

8845-31, Session 7

Ultrafast four wave mixing holographic imaging *(Invited Paper)*

Yonggang Lu, Guanyu Liu, Peking Univ. (China); Kebin Shi, Peking Univ, (China)

Holography has been long known for its unique capability of retrieving both amplitude and phase of the heterodyne-recorded optical field. It has found important applications in three dimensional imaging and display since its inception. Original holographic imaging apparatuses have primarily been developed upon the linear contrast mechanisms as exemplified by linear scattering and reflection. On the contrary, nonlinearly generated signal from specimen is known to deliver more explicit information for better characterizing samples in various scientific fields such as biology and material research. Holographic imaging utilizing nonlinear contrast mechanism has been investigated recently. For example, holographic recording of second harmonic generation (SHG) from specimen's intrinsic structure or labelled nonlinear nano-crystal has been reported. The recorded holography enables full three dimensional field retrieval and phase conjugation imaging. Here we report on a nonlinear holographic imaging apparatus based on heterodyne recording of wide-field four wave mixing (FWM) signal. With Raman or surface plasmonic resonance enhancement, single shot recording with pulse duration of 22ps can be achieved. We will present our recent results on different categories of samples such as colloidal particles and metallic nano-rods. Techniques for non-resonant background suppression will also be discussed in this report.

8845-32, Session 7

High-speed volumetric fluorescence and nonlinear microscopy through phase-encoded axial position *(Invited Paper)*

Randy A. Bartels, Jeffrey J. Field, Colorado State Univ. (United States); Daniel J. Higley, Stanford Univ. (United States); David R. Smith, David G. Winters, Colorado State Univ. (United States)

Holographic imaging has gained favor in the biosciences for its rapid collection of volumetric data. While holography does not exhibit optical sectioning, and hence does not give true three-dimensional data, phase information encoded into a hologram means that it can be digitally re-focused to create a three-dimensional representation of the specimen. Digital holographic microscopy (DHM) with harmonic generation allows full three-dimensional reconstructions of the specimen. While these volumetric reconstructions have high fidelity with the specimen, a major limitation of standard DHM is that the contrast signal must be spatially coherent, ruling out fluorescence measurements, since the defocus phase cannot be measured directly. Instead, the signal originating from the specimen is made to interfere with a reference beam, and the resulting interferogram encodes the spatial phase information. However, by applying varied temporal modulations to the spatial extent of a line focus within the specimen, we show that the same spatial defocus phase is encoded into the spatially coherent illumination beam in spatial-frequency-modulated imaging (SPIFI), thereby relaxing the condition that the contrast signal be spatially coherent to perform volumetric reconstructions. Moreover, a key component of SPIFI is spatial

integration of the contrast intensity onto a single-element detector, encoding the spatial frequency content of the specimen in the resulting temporal signal. The combination of whole-field imaging and volumetric reconstructions at or beyond video rates makes fluorescent SPIFI an attractive alternative to slower volumetric techniques such as laser-scanning microscopy.

8845-33, Session 7

Multifocal multiphoton imaging and micro-machining with spatio-temporal focusing *(Invited Paper)*

Jeff A. Squier, Colorado School of Mines (United States)

Multifocal multiphoton imaging that enables the direct acquisition of three-dimensional volumes with single element detection is demonstrated. This system is capable of image acquisition rates of 30 frames per second, enabling capture of dynamic processes in volume. In addition, as a result of the novel detection scheme, weak signals such as harmonics can be detected simultaneously along with multiphoton fluorescence signals in a single detector without the use of frequency selective filters for the first time. In conjunction with this imaging system, a novel tissue ablation system has been developed that incorporates spatio-temporal focusing which enables precise ablation at fluences well above threshold. In many biological systems there is an ablation threshold disparity that complicates tissue cutting. An excessively tough region of tissue may mitigate the application of femtosecond ablation due to the increase in the ablation threshold. The approach detailed here over comes this limitation. Finally, this system will permit novel surgical implementations where low numerical apertures and long working distances are desired as a dictated by the geometry of the biological system.

8845-34, Session 7

Parallel axial imaging in scanning microscopy

Chuan Yang, The Pennsylvania State Univ. (United States); Kebin Shi, Peking Univ. (China); Mingda Zhou, Ding Ma, Venkatraman Gopalan, Shizhuo Yin, Siyang Zheng, Zhiwen Liu, The Pennsylvania State Univ. (United States)

In conventional scanning optical microscopy, several techniques have been developed to realize high-speed scanning in lateral (x-y) dimensions. However, to achieve 3-D microscopic imaging, slow mechanical scanning of the objective lens or the specimen itself in the z direction is typically required, which impedes the development of the capability for imaging fast processes in the axial direction. We discuss a method for effective axial scanning, in which chromatic aberration is exploited to focus different wavelengths of an excitation beam into different axial positions, and demonstrate parallel axial imaging in both second harmonic microscopy and two-photon fluorescence microscopy. In second harmonic (SH) microscopy, SH signals with different doubled frequencies can be generated at different axial positions, and can therefore be detected in parallel by using a spectrometer, while in two-photon fluorescence imaging, an array of 45°-tilted micro mirrors is used to reflect fluorescence signals emitted from different depths of the specimen onto an image sensor for parallel detection. Both experimental results and numerical analysis will be presented.

8845-35, Session 8

Simplified two-beam hybrid fs/ps CARS demonstrated in 1D and 2D *(Invited Paper)*

Christopher Kliewer, Sandia National Labs., California (United States)

We explore a novel phase matching scheme for gas-phase rotational coherent anti-Stokes Raman spectroscopy (CARS). The scheme significantly simplifies the employment of the technique in general. Two laser beams, one broadband and one narrowband, are crossed at arbitrary angle and the generated rotational CARS signal, copropagating with the probe beam, is isolated using a polarization gating technique. The effect of phase-vector mismatch for various experimental implementations was measured experimentally and compared to calculations. The spatial resolution of the current technique is improved by more than an order of magnitude over standard gas-phase CARS experimental arrangements, providing an interaction length of less than 50 µm when desired. Both the pump and Stokes photons originate from the broadband pulse, and are therefore automatically overlapped temporally and spatially. Significantly improved signal levels are achieved because of both the ease of alignment and the higher pulse energy available to the pump and Stokes fields. We demonstrate the technique for single-laser-shot 1D RCARS signal generation over approximately a 1 cm field in a flame. Perhaps most importantly, the novel phase-matching scheme enables the generation of CARS signals in 2D within a single laser shot. Such spatially correlated data is of high importance for relating experimental measurements to high-fidelity numerical simulations of combustion, for instance.

8845-36, Session 8

Femtosecond Raman force spectroscopy *(Invited Paper)*

Eric O. Potma, Dmitry Fishman, Junghoon Jahng, Jordan Brocious, H. Kumar Wickramasinghe, Jon Burdett, Fei Huang, Univ. of California, Irvine (United States)

In a conventional stimulated Raman scattering (SRS) measurement, changes in photon occupation number of the incident pump and Stokes beams are measured in the far-field, which reports on successful Raman transitions in the molecules in focus. However, detecting stimulated Raman transitions grows exceedingly more challenging when approaching the single molecule limit, as the change in the photon occupation number becomes significantly lower than the magnitude of the intrinsic Poisson noise of the incident beams. Direct measurement of successful Raman transitions in the near field through non-optical detection can avoid the unfavorable photon statistics that complicate far-field SRS measurements in this low copy number limit.

One non-optical detection approach is based on monitoring light-induced changes in the attractive force between a dipole and its corresponding image in a metal tip. Any optical transition, including Raman transitions, may bring about change in the local image force, which can in turn be measured with a cantilevered tip. When frequency modulating both the pump and Stokes beams, Raman induced changes in the image force can be detected in the cantilever mechanical response at the difference frequency of the modulation. This principle was recently shown for the case of continuous light illumination. In this work, we demonstrate that this method can be extended to the case of femtosecond SRS. We show that time-resolved pump-probe and Raman induced transitions can be measured with the femtosecond Raman force microscope in molecules present at low copy numbers.

8845-37, Session 8

Coherence in UV resonance Raman spectroscopy of liquid benzene and toluene *(Invited Paper)*

Hans D. Hallen, North Carolina State Univ. (United States); Adam H. Willitsford, Johns Hopkins Univ. Applied Physics Lab. (United States); C. Todd Chadwick, C. Russell Philbrick, North Carolina State Univ. (United States)

We have measured UV resonance Raman near and at the resonance absorption lines of liquid benzene and toluene. Resonance absorption with excitation on the symmetry-forbidden but strongly phonon coupled 1B2u band, ~230-270 nm, presents enhancement according to the vapor phase absorptions rather than those of the liquid phase. This effect is related to the coherence forced by the internal molecular resonance required to absorb light at this energy. The resonance gains (~1000x) are larger than expected due to the narrower vapor phase lines. Several multiplets and overtone modes are enhanced along with the strongly-coupled ring breathing mode.

8845-38, Session 8

Raman spectroscopic sensing using whispering gallery microresonators

Perry S. Edwards, Corey Janisch, The Pennsylvania State Univ. (United States); Bo Peng, Lan Yang, Washington Univ. in St. Louis (United States); Zhiwen Liu, The Pennsylvania State Univ. (United States)

We investigate resonator enhanced Raman spectroscopy as a label-free method toward single particle sensing. Whispering gallery mode microresonators are used as platforms to perform sensitive particle detection by exploiting the strong, evanescent field of a resonant mode exposed on the surface of the microresonator. Particles adhered to the microresonator surface interact with the field and inelastically scatter photons circulating within the resonator. In particular, Raman scattered photons are detected, providing molecular-specific “fingerprint” information regarding the adhered particles. The exploitation of a resonant mode allows for enhancement of generated Raman signal over traditional methods of spontaneous Raman scattering. Experimental results will be shown demonstrating the resonator enhancement.

8845-39, Session 8

High-speed coherent Raman imaging (CRI) of cells and tissues with broadband coherent anti-Stokes Raman scattering (BCARS)

Charles H. Camp Jr., Young J. Lee, Christopher M. Hartshorn, Marcus T. Cicerone, National Institute of Standards and Technology (United States)

Raman microspectroscopy is a powerful tool for the analysis of chemical species within biological samples, but with pixel dwell times on the order of seconds to minutes, its use as a high-throughput imaging modality is limited. We present our development of a high-speed coherent Raman imaging (CRI) microscope based on broadband coherent anti-Stokes Raman scattering (BCARS) that utilizes fiber laser sources and a CMOS camera-equipped spectrograph allowing pixel rates down to 160 microseconds with spectra spanning approximately 480 – 4550 cm-1. The system utilizes two fiber laser sources (a 1.5 ps probe source and a 16 fs compressed supercontinuum source) emanating from the same mode-locked seed source that provides attosecond synchronization, high system stability, and ~11 cm-1 spectral resolution in a compact footprint. Additionally, the intrapulse Raman excitation from the supercontinuum source generates strong spectral response within the fingerprint region, especially at low wavenumbers. Although the use of extremely short laser excitation pulses leads to a dramatic enhancement in the nonresonant background (NRB), the use of a modified Kramers-Kronig algorithm provides background-free Raman response extraction with extremely high numerical efficiency. This system provides a platform for high-speed, broadband CRI that opens up the practical application to live cells, tissues, and high throughput screening. To demonstrate these achievements, we will present chemical imaging of brain and cancer tissues with morphological and spectral signatures, as well as, cultured cells with chemically identified organelles.

8845-40, Session PMon

Diagnosis of liver disease using a multimodal multiphoton optical microspectroscopy image

Jang Hyuk Lee, Jong Chul Kim, Giyoong Tae, Myoung-kyu Oh, Do-Kyeong Ko, Gwangju Institute of Science and Technology (Korea, Republic of)

Liver fibrosis is characterized by the excessive accumulation of extracellular matrix (ECM) proteins including collagen, which occurs in most types of chronic liver diseases. Our goal is to develop multimodal multiphoton nonlinear optical microspectroscopy imaging system and efficiently investigate the fibrotic liver disease by multimodal images and coherent anti-Stokes Raman scattering (CARS) spectrum. CARS microspectroscopy was integrated with other multiphoton microscopy techniques, two-photon excitation fluorescence (TPEF) and second harmonic generation (SHG) microscopy, in one platform. It was applied to liver disease samples such as liver fibrosis tissue and cirrhosis. As a result, normal and liver disease sample were exactly distinguished because of the great difference by CARS spectra as well as multimodal multiphoton nonlinear optical images. A few collagens and hepatic lipid droplets were observed in normal tissue while a lot of aggregated collagen fibers and hepatic lipid droplets were clearly visualized in liver disease tissue by SHG and CARS microscopy images, respectively. We expect the system as a great early diagnosis tool for liver fibrosis by detecting an early stage of liver disease at tissue level.

8845-41, Session PMon

Portable multispectral imaging system for oral cancer diagnosis

Yao-Fang Hsieh, National Central Univ. (Taiwan); Mang Ou-Yang, National Chiao Tung Univ. (Taiwan); Cheng-Chung Lee, National Central Univ. (Taiwan)

This study presents the portable multispectral imaging system that can acquire the image of specific spectrum in vivo for oral cancer diagnosis. The system can acquire the spectral and spatial information simultaneously. According to the research literature, the autofluorescence of cells and tissue have been widely applied to diagnose oral cancer. The spectral distribution is difference for lesions of epithelial cells and normal cells after excited fluorescence. We have been developed the hyperspectral and multispectral techniques for oral cancer diagnosis in three generations. This research is the third generation. The excited and emission spectrum for the diagnosis are acquired from the research of first generation. The portable system for detection of oral cancer is modified for existing handheld microscope . The UV LED is used to illuminate the surface of oral cavity and excite the cells to produce fluorescent. The image passes through the central channel and filter out unwanted spectrum by the selection of filter, and focused by the focus lens on the image sensor. Therefore, we can achieve the specific wavelength image via fluorescence reaction. The specificity and sensitivity of the system are 85% and 90%, respectively.

8845-42, Session PMon

Upconversion of infrared radiation in PbSe/CdSe core-shell colloidal quantum dots

Nikolay S. Makarov, Qianglu Lin, Weon-Kyu Koh, Victor I. Klimov, Los Alamos National Lab. (United States)

Large two-photon absorption cross sections are of immediate interest for various applications including volumetric optical memory, three-dimensional microscopy, optical power limiting, photodynamic therapy, and solar energy conversion. Core-shell colloidal quantum dots are optimal for engineering of large two-photon absorption cross sections due to solution-based processibility of these nanomaterials and fairly

straightforward manipulation of optical resonances by varying the dimensions of the core and the shell independently from each other.

Here, we have examined a series of PbSe/CdSe core-shell colloidal quantum dots of various sizes (shell thickness 1 3 nm and core diameter 4 8 nm). All of these samples show dual emission with the infrared band due to PbSe-core and the visible band originating from the CdSe shell. We have measured two-photon absorption cross sections of the quantum dots by monitoring visible up-converted emission, excited with the infrared fs laser pulses that are in the range of optical absorption of the PbSe core. Quadratic dependence of the visible emission intensity on excitation power confirms a two-photon excitation mechanism. The measured two-photon absorption cross sections are about one order of magnitude larger than those of core-only CdSe quantum dots and reach up to ~2x10^6 GM for apparent values and ~3x10^7 GM for the values corrected for the local field factor. We explain such an increase in the cross sections by resonance enhancement due to core absorption. We have also examined a possibility of Auger-assisted up-conversion in samples with smaller core sizes and thicker shells. Our study demonstrates that the use of core/shell structures represents a promising approach for obtaining enhanced two-photon absorption cross-sections.

8845-43, Session PMon

1D-scanning addressable multiregional multifocal multiphoton microscopy

Wan Qin, Clemson Univ. (United States); Yonghong Shao, Shenzhen Univ. (China); Honghai Liu, Clemson Univ. (United States); Xiang Peng, Hanben Niu, Shenzhen Univ. (China); Bruce Z. Gao, Clemson Univ. (United States)

Multiphoton laser scanning microscopy is capable of three-dimensionally imaging thick specimens with high resolution without confocal pinholes. But due to the low scanning rate, it cannot be applied to imaging samples with dynamic behavior. One of the first methods designed to improve scanning rate is line scanning, in which the excitation laser is focused with a cylindrical lens to create a line focus on the sample plane, making one of the two lateral scans unnecessary. Line focus can, however, cause cross-talk because of the lack of confocal gates. Interference on out-of-focus planes occurs between adjacent points when they are too close, degrading the resolution of the imaging system. In this study, we developed a novel addressable multiregional multiphoton microscope that employs a fast one-dimensional discrete-line scanning approach based on a spatial light modulator (SLM). The phase-only SLM shapes an incoming mode-locked, near-infrared Ti:sapphire laser beam into multiple specific discrete-lines, which are designed according to the sizes and locations of the target samples. Only the target-sample areas are scanned one-dimensionally, resulting in an efficient use of the laser's power. Compared with conventional multiphoton microscopies, this technique shortens scanning time and minimizes photodamage by concentrating scanning energy and dwell time on the areas of interest. This increase of imaging speed is critical for recording very fast process of live samples. Additionally, our discrete-line-focus design eliminates the cross-talk that occurs in conventional one-dimensional line-scanning multiphoton microscopes, thus enhancing the lateral and axial resolutions of the line-scanning imaging system.

8845-44, Session PMon

Spectroscopic assessment of the water molecule in liquid state valent angle

Boris A. Okhrimenko, Rostyslav N. B. Danylo, National Taras Shevchenko Univ. of Kyiv (Ukraine)

Our research is devoted to the vibrational spectroscopy inverse problem solution that gives a possibility to make conclusions about the investigated molecule geometry, in particular an assessment of water molecule in the liquid state valent angle.

3N-matrix method was applied to solve the inverse vibrational spectroscopy problem. There is an ability to make no assumption about the molecule force field. An anharmonicity of both characteristic and noncharacteristic vibrations always exists so there is a reason to do a correction caused by the anharmonicity. For this purpose, the formula

??0i= ??i(1+ui ??i)

was used, where ??I is the frequency that is determined experimentally, ??0i is the zero vibrations frequency, and ui is an anharmonicity constant analogue. Taking molecules interaction into account made it possible to insert noncharacteristic vibration frequencies into calculations. The 3N-martix method use simplifies u3 constant calculating. Finding u1 and u2 values was our next step.

Analytic expressions for force matrix elements permitted to find the matrix explicit form. This matrix was used to solve the direct vibrational spectroscopy problem. Found normal characteristic vibrations frequencies were compared with those ones determined experimentally using divergence parameter. The formula

y=(1-??1,theor/??1,exp)2+(1-??2,theor/??2,exp)2+(1-??3,theor/??3,exp)2

was used to define the divergence parameter. ??theor is a calculated theoretically frequency, ??exp is a measured experimentally frequency. The defined divergence parameter is a function of valent angle ??. The valent angle assessment was reduced to the divergence parameter minimization. The ?? value concerning divergence parameter minimum was interpreted as a desired valent angle. According to all assumptions ??=89°.

Optical parametric oscillators synchronously pumped by fundamental and second harmonic radiation of femtosecond Yb:KGW laser

Karolina Stankevi?i?t?, Ieva Pipinyt?, Julius Vengelis, Vilnius Univ. (Lithuania); Rimantas Grigonis, Vilnius Univ. (Lithuania) and Light Conversion Ltd. (Lithuania); Robert C. Eckardt, Gooch & Housego, Cleveland (United States); Valdas Sirutkaitis, Vilnius Univ. (Lithuania)

There are many applications where ~75 MHz repetition rate continuously tunable femtosecond pulses are needed. In such cases synchronously pumped optical parametric oscillators (SPOPOs) pumped by continuous trains of femtosecond pulses ? have to be used. Today most commercially available SPOPOs are pumped by first or second harmonics of femtosecond Ti:sapphire lasers, but in the past five years femtosecond Yb:KGW lasers systems emerged in industry and research facilities. This gives an opportunity to create compact, more efficient and cheaper continuously wavelength tunable ultrashort pulse systems with pulse durations from ~100 fs to ~3 ps. In this report we present results obtained during investigation and construction of SPOPO's pumped by fundamental (1030 nm) and second harmonic (515 nm) of Yb:KGW laser providing 105 fs pulses at 76 MHz repetition rate with average output power 4 W and 2.4 W at 1030 nm and 515 nm wavelength, respectively. BBO and BiBO nonlinear crystals were tested in SPOPO pumped by 515 nm pulses in order to achieve wavelength tuning in 630 – 2000 nm range. For wavelength tuning in 1400-4000 nm range PPLN crystal was tested in SPOPO pumped by 1030 nm pulses. Wavelength tuning capabilities via rotation of nonlinear crystal, SPOPO cavity length or PPLN grating period variation were investigated. Generation thresholds and output powers at different signal wavelengths were determined in SPOPO cavities with and without dispersion compensation.

Performance evaluation of hybrid VLC using device cost and power over data throughput criteria

Chia Ching Lee, Ching Seong Tan, Hin Yong Wong, Multimedia Univ. (Malaysia); M. B. Yahya, TM R&D (Malaysia)

Visible light communication (VLC) technology has been gaining attention in both academia and industry recently. It is driven by the progress of light emitting diode (LED) technology for solid-state lighting (SSL). It has great potential to gradually replace radio frequency (RF) wireless technology as it offers huge, unregulated, unlicensed bandwidth to cope with future demand of indoor wireless access to real–time bandwidth-intensive applications. However, it was found to provide intrusive uplink channel that give rise to unpleasant irradiance from the user device which could interfere with the downlink channel of VLC and hence limit mobility to users as a result of small coverage (field of view of VLC).To address this potential problem, a Hybrid VLC system which integrates VLC (for downlink) and RF (for uplink) technology is proposed. It offers a non-intrusive RF back channel that provides high throughput VLC, maintains durability with conventional RF devices, and demonstrates excellent scalability .To deploy Hybrid VLC system in the market, it must be energy and cost saving to attain its equivalent economical advantage by comparing to existing architecture that employs fluorescent or LED lights with RF technology. In this paper, performance evaluation on the proposed hybrid system was carried out in terms of device cost and power consumption against data throughput. Based on our simulation ,Hybrid VLC system was found to reduce device cost by 3% and power consumption by 68% when compare to fluorescent lights with RF technology . Nevertheless, when it is compared to LED lights with RF technology, our proposed hybrid system is found to achieve device cost saving as high as 47% and reduce power consumption by 49%. Such promising results have demonstrated that Hybrid VLC system is a feasible solution and has paved the way for greater cost saving and energy efficient compares with the current RF architecture even with the increasing requirement of indoor area coverage.

Enhanced optical second-harmonic generation from current-biased graphene on a SiO2/Si(001) substrate

Yong Q. An, Je-Ung Lee, Alain C. Diebold, Univ. at Albany (United States)

Recent theoretical calculations have predicted that electrically biased graphene can be a nonlinear optical material with giant nonlinearity. Experimental exploration of such giant nonlinearity is an important step toward implementing the electro-optical effect in graphene based devices. Field-effect transistors (FET) with graphene channels are suitable structures for nonlinear optical studies of graphene, because the graphene film in the channel region can be easily biased by an electric current or field and its transparency allows for nonlinear optical measurements. Nonlinear optical studies of graphene FET channels will elucidate new opportunities for combining high electron mobility with giant optical nonlinearity resulting in new optoelectronic devices. We have used a mm-sized FET-like graphene/SiO2/Si(001) structure to study the character and mechanism of electric current-induced second-harmonic generation (CI-SH) in graphene. We find that optical second-harmonic generation (SHG) in reflection from a chemical-vapor-deposition graphene monolayer on a SiO2/Si(001) substrate is enhanced about 3 times by the flow of direct electric current in graphene. Measurements of rotational-anisotropy SHG revealed that the CI-SH from the graphene/SiO2/Si(001) structure varies strongly by undergoing a phase inversion as the measurement location on graphene is shifted laterally along the current flow direction. Measurements of field-induced SHG on the graphene/SiO2/Si(001) structure and CI-SH on a graphene/glass structure indicated that the CI-SH enhancement is due to current-associated charge trapping at the graphene/SiO2 interface, which introduces an electric field across the SiO2/Si interface that produces field-induced SHG. The phase inversion is due to the positive-to-negative polarity switch of the trapped charges at the graphene/SiO2 interface.

Conference 8846: Terahertz Emitters, Receivers, and Applications IV

Sunday - Monday 25–26 August 2013

Part of Proceedings of SPIE Vol. 8846 Terahertz Emitters, Receivers, and Applications IV

8846-1, Session 1

Room temperature compact THz sources based on quantum cascade laser technology *(Invited Paper)*

Manijeh Razeghi, Northwestern Univ. (United States)

The terahertz (THz) spectral range is important for numerous applications in imaging, spectroscopy, and biological engineering. A compact, room temperature, tunable THz source is desirable for versatility and ease of integration. Thanks to recent development of high power mid-infrared (mid-IR) quantum cascade lasers (QCLs) and nonlinear mixing; a semiconductor THz source is realized with the same footprint of a mid-IR QCL, along with other features such as room temperature operation, electrical pumping, and wavelength tunability. We have demonstrated room temperature single mode THz emission across a wide frequency range of 1 – 4.6 THz. The highest THz output power is 180 ?W. By further optimizing the phase matching scheme, waveguide geometry, and pump powers, mW-level THz powers are projected at room temperature.

8846-2, Session 1

Injection schemes in quantum cascade lasers under operation *(Invited Paper)*

Martin Lindskog, David O. Winge, Andreas Wacker, Lund Univ. (Sweden)

The Quantum Cascade Laser (QCL) is a promising device for a large variety of THz applications. However up to date, the operation is limited to temperatures just below 200 K, as recently obtained by a device with a standard tunneling injection design [1]. In order to reach higher temperatures, the scattering injection scheme [2] appears promising, which was shown to operate under conditions, where the thermal energy widely exceeds the photon energy [3].

In our group, we have developed a simulation tool [4] based on nonequilibrium Green's functions, which allows for a quantitative modeling of QCLs taking fully into account quantum coherence. We provide recent examples of Terahertz QCLs with scattering [5] and tunneling [6] injection, where we can analyze the operation in detail. Based on our recent extension of the model to include high lasing fields [6,7], we show how the different injection schemes perform under lasing conditions.

8846-3, Session 1

Terahertz quantum-cascade lasers with composite right/left handed metamaterial waveguides and antennas *(Invited Paper)*

Benjamin S. Williams, Amir A. Tavallaee, Philip Hon, Tatsuo Itoh, Univ. of California, Los Angeles (United States); Qisheng Chen, Northrop Grumman Aerospace Systems (United States)

The composite right/left-handed (CRLH) transmission line metamaterial has been used in the microwave frequency range to demonstrate novel guided wave and radiating devices, including leaky-wave and resonant antennas. CRLH structures exhibit a dispersion relation that supports backward-wave (left-handed) propagation, zero-index propagation, as well as forward-wave (right-handed) propagation. A CRLH transmission line metamaterial can be obtained by loading a conventional transmission line with series capacitance and shunt inductance. We have designed and implemented CRLH waveguides in THz quantum-cascade laser metal-metal waveguide, where series capacitance is obtained by adding capacitive gaps in the upper metallization and effective shunt inductance is obtained by operating in a higher order lateral mode. In this scheme, the GaAs/AlGaAs multiple quantum well quantum-cascade material is the dielectric of the transmission line – when properly injected with current it provides THz amplification via stimulated emission of photons due to intersubband radiative transitions. A CRLH leaky-wave antenna will radiate at an angle ?=sin-1 (?/k0), where ? is the propagation constant. We have demonstrated an active CRLH antenna fed by a THz quantum-cascade laser which can radiate in a backward, surface normal, or forward direction, depending upon the frequency of excitation. These CRLH metamaterial waveguides provide a flexible platform for future THz sources with advanced functionality, including frequency tuning, integrated phase/amplitude modulation, beam steering and shaping.

8846-4, Session 1

Quantum cascade lasers: a versatile and narrow-linewidth source in the terahertz range *(Invited Paper)*

Miriam S. Vitiello, Consiglio Nazionale delle Ricerche (Italy)

Quantum Cascade Lasers (QCLs) witness how materials engineering can actually forge objects that, with conventional technologies, could never exist. Being fully designed from scratch, they represent a powerful testing ground for fundamental properties relying on the quantum nature of the device.

Despite the cryogenic operation temperatures ($\leq$ 199.5 K), QCLs working in the far infrared have now a realistic chance to deeply impact technological applications, thanks to the high output power (>100mW), the quite broad operating frequency range (1.2-4.7 THz), the coherence and the compactness. Frequency- and phase-stabilized, high-power and reliable, solid-state terahertz sources can indeed find application in a large number of fields spanning from far-infrared astronomy and high-precision molecular gas spectroscopy, to high resolution coherent imaging and telecommunications, providing the carrier wave for broadband wireless links.

Experimental evidence of intrinsic linewidth (LW) values approaching the quantum limit in THz QCLs is here reported together with their potential in polarization spectroscopy experiments addressed to high sensitivity molecular detection. Highlighting the key role of the gain medium engineering, we demonstrate that properly designed semiconductor-heterostructure lasers could unveil the mechanisms underlying the laser intrinsic phase-noise, revealing the link between the device quantum properties and its quantum-limited LW.

In addition, recent results on the phase-locking of 2.5 THz QCLs to a free-space comb, generated in a $LiNbO_3$ waveguide and covering the 0.1–6 THz frequency range will be presented. The described approach paves the way to novel metrological-grade terahertz applications, including high-resolution spectroscopy, measurement of the absolute frequency, manipulation of cold molecules.

8846-5, Session 1

New materials and THz QCLs for radio-astronomy applications *(Invited Paper)*

Jérôme Faist, Keita Ohtani, Mattias Beck, Giacomo Scalari, Dana Turcinkova, Christofer B. Bonzon, ETH Zurich (Switzerland)

The quantum cascade laser (QCL) has demonstrated operation over an extremely wide wavelength range extending from the mid-infrared at 2.9?m to the Terahertz at 360?m. In addition, quantum cascade lasers operating in the mid-infrared have now demonstrated extremely high powers (>1W c.w.) with increasingly high wallplug efficiencies (>25%). These achievements require the design of very complicated sequences of layers with Angstrom accuracy.

In the terahertz, devices, taking advantage of the tight confinement provided by the metal-metal waveguide, we also have explored third order photonic wire lasers as well as photonic crystal quantum cascade lasers. In a further development, LC resonator cavities enable us to explore the coupling between transport and photon emission in the regime of very subwavelength emitters, as the ratio of volume over lambda cube is much below unity.

The present limitations of THz quantum cascade lasers to operation at temperature outside the reach of thermoelectric Peltier cooler has spurred new approaches that rely on different materials. We will discuss results from our group were we have worked on InAs and InGaAs – based materials with ternary and quaternary barriers. Laser devices with very low threshold current densities (<60A/cm2) have already been demonstrated.

In addition, we will discuss some recent results we have achieved at 4.7THz relevant for radio astronomy as well as the prospects for very tunable devices

8846-6, Session 2

Reconfigurable diamagnetic meta-molecules for broadband terahertz modulation *(Invited Paper)*

Mehmet Unlu, Christopher W. Berry, Mohammad R. Hashemi, Shang Hua Yang, Mona Jarrahi, Univ. of Michigan (United States)

Metamaterials offer a very promising platform for manipulating terahertz waves since their spectral response can be engineered by their geometry, rather than being limited by the characteristics of natural materials at terahertz frequencies. However, the operation bandwidth of the demonstrated metamaterial-based terahertz modulators has been limited by the resonant nature of the employed device configurations. Here, we present a broadband terahertz modulator based on a new class of reconfigurable meta-surfaces with switchable diamagnetic meta-molecules, which enables radical changes in the device scattering parameters over a broad range of terahertz frequencies. Switching the diamagnetic properties of the meta-molecules is made possible through changing their structural configuration by integration of the meta-surface structure with an array of electrostatically actuated MEMS switches. In contrast to the previously demonstrated MEMS-reconfigurable terahertz metamaterials, the electromechanical displacement required for structural reconfiguration is less than 250 nm in the presented terahertz meta-surface, enabling device operation at low modulation voltages and high modulation speeds. We experimentally demonstrate more than 70% modulation depth over a 1.5 THz frequency band, under a modulation voltage of 30 V and modulation speeds exceeding 20 KHz. The achieved modulation depth is the highest reported among previously demonstrated terahertz intensity modulators, in general, and 5 times higher than the demonstrated broadband terahertz modulators with similar modulation voltages and modulation speeds, specifically.

8846-7, Session 2

Gradient index devices for terahertz waves and terahertz surface waves *(Invited Paper)*

Marco Rahm, Martin Volk, Tassilo Fip, Jens Neu, Michael Höh, Benjamin Reinhard, Technische Univ. Kaiserslautern (Germany)

Gradient index (GRIN) optics has a long-term history that originates from ideas that were developed in the 19th century by Maxwell. While most of these concepts could not be put into reality due to a lack of suitable electromagnetic media, the birth of metamaterials in the late 90s enabled the practical implementation of such devices in an unprecedented manner.

Here, we demonstrate a variety of GRIN devices for both freely propagating terahertz waves and terahertz surface waves. As specific examples of static GRIN optics we experimentally investigated and measured the optical properties of a focusing terahertz GRIN lens with sub-wavelength focusing capabilities. Moreover, we devised and fabricated a terahertz beam deflector with a maximum deflection angle of 4.2 deg. The thickness of the beam deflector was only about 100 µm which is sub-wavelength at a frequency of 1.3 THz. In this context, we also discuss various concepts for the design and implementation of adaptive GRIN optics with tunable optical properties. For example, we theoretically investigated and optimized an approach that is suitable for the fabrication of a focusing terahertz GRIN lens with variable focus length and focus size.

Another intriguing concept is the use of specifically designed meta-surfaces that support strongly confined terahertz surface waves. We show that the surface waves can be deliberately guided within the plane of propagation by use of GRIN structures. For example, we evidenced the focusing behavior of a meta-surface GRIN lens by near-field mapping of the terahertz field.

8846-8, Session 2

Coupled polaritons and antipolaritons in dispersive gain media

Mauro F. Fernandes Pereira Jr., Sheffield Hallam Univ. (United Kingdom)

In this paper we predict how a material excitation with a dispersive gain profile couples with light in a microcavity. We show that even a single transition yields an interacting set of coupled intersubband polariton [1] and antipolariton [2] branches which can potentially lead to a new level of all-optical control and switching in a microcavity. In contrast to the conventional antipolariton case with an imaginary Rabi frequency, the dilute nitride quantum wells chosen [3] show ample flexibility to engineer the dispersive gain shape without global inversion and have potential for real Rabi frequencies with measurable oscillations, suggesting this as the medium of choice to investigate the coupling of photonic modes with an excitation delivering dispersive gain.

Scattering of terahertz radiation in thin layers of dielectric materials

Irina Fokina, Kirill I. Zaytsev, Valeriy E. Karasik, Stanislav Yurchenko, Konstantin P. Tsapenko, Bauman Moscow State Technical Univ. (Russian Federation)

Terahertz radiation is used for different applications including time-domain spectroscopy, diagnostics of human tissue diseases, nondestructive test of composite materials, identification of drugs and explosives. Since it is important to obtain spectroscopic information in all these applications, there is a specific interest in studying processes of reducing useful information.

Spectral characteristics of inhomogeneous medium are distorting because of scattering inside this medium. In another case if a medium of interest is covered by another material, which is considered to be transparent for THz radiation, a received signal is scattered in this covering layer.

In this work scattering of THz radiation in thin layers of dielectric material was studied. Particularly, fabric materials were chosen. Scattering was modeled by the use of numerical solution of Maxwell equations by using the finite-difference time domain method. For modeling the structure of fabric, a model of infinite cylinders array was considered. Scattering cross-section and indicatrix were obtained. Then spectral transmittance was computed.

During a set of experiments THz spectral transmittance of various fabric materials were obtained. These experiments showed that for purpose of designing THz visual system for detecting concealed under clothes objects it is essential to select working frequencies lower than 1 THz.

Confrontation of the numerical and experimental results was carried out.

The developed method for obtaining scattering characteristics of different materials can be used for extracting useful information from received THz signal.

8846-10, Session 2

Ultra-strong light-matter interaction with mid-infrared metamaterials *(Invited Paper)*

Alexander Benz, Sandia National Labs. (United States); Salvatore Campione, Univ. of California, Irvine (United States); Sheng Liu, Ines Montano, John F. Klem, Michael B. Sinclair, Sandia National Labs. (United States); Filippo Capolino, Univ. of California, Irvine (United States); Igal Brener, Sandia National Labs. (United States)

Ultra-strong coupling is a new regime of light-matter interaction and a highly active field of research. In this regime the energy exchange rate between an optical cavity and a two-level system becomes similar to the fundamental system oscillation itself. One of the immediate outcomes is the non-classical nature of the ground state being squeezed vacuum containing only a finite number of virtual photons.

Here, we present experimentally the strong light-matter coupling of a metamaterial mode and an intersubband transition (ISTs) in the mid-infrared (MIR) spectral range. We use a conventional two-dimensional metallic meta-surface processed on top of semiconductor heterostructures designed with ISTs around 10 um. Upon tuning, the single resonance splits into the two polariton branches; the maximum splitting reaches 15% of the central frequency. Additionally, we have also measured the ultra-fast energy exchange directly using a novel time-domain spectroscopy system. We can observe clearly the Rabi oscillation with a period of 480 fs, corresponding to a Rabi frequency of 2.1 THz. We will further discuss a new strong coupling formalism that takes into account many body effects and strong exciting light fields.

This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. Department of Energy, Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000. #158883

8846-11, Session 3

Room-temperature terahertz oscillation of resonant tunneling diodes *(Invited Paper)*

Masahiro Asada, Safumi Suzuki, Tokyo Institute of Technology (Japan)

Our recent results of a room-temperature THz oscillator using a resonant tunneling diode (RTD) are reported. This oscillator is composed of a GaInAs/AlAs double-barrier RTD and a planar slot antenna. The maximum frequency of oscillation in RTDs is limited by the delay time of electrons across the RTD layers, which consists of the dwell time in the resonant tunneling region and the transit time across the collector depletion region. The dwell time was reduced by a narrow well, and a fundamental oscillation up to 1.31 THz with the output power of 10 microwatts was achieved at room temperature. For further increase in oscillation frequency, we proposed a composite collector structure for the reduction of collector transit time. In this structure, the electron transition between the gamma and L conduction bands, which causes a long transit time, can be suppressed, and a fundamental oscillation up to around 2 THz is theoretically possible. For high output power, coherent power combining was demonstrated in a two-element array with offset slot antennas coupled with each other, and 610 microwatts at 620 GHz was obtained. Spectral characteristics were measured with a heterodyne detection, and the linewidth of less than 10 MHz was obtained. 1-5 percent frequency change with bias voltage was also observed, which is attributed to the bias-dependent dwell time. Direct intensity modulation with bias voltage and wireless data transmission were demonstrated. A transmission rate of 3 Gbps with the bit error rate of 3e-5 was obtained at 540 GHz in a preliminary experiment.

8846-12, Session 3

THz sources using indium phosphide high electron mobility transistors *(Invited Paper)*

William R. Deal, Northrop Grumman Corp. (United States)

THz power generation has long limited the types of practical applications at THz frequencies. With new improvements in maximum frequency of oscillation (fMAX), integrated circuits can now be realized which multiply and then amplify signals at frequencies approaching 1 THz. An overview in Northrop Grumman's technical progress at realizing THz sources will be presented.

8846-13, Session 3

Terahertz emitters based on impurity transitions in semiconductors *(Invited Paper)*

James Kolodzey, Univ. of Delaware (United States)

Terahertz emitters are important for fundamental studies in this interesting frequency regime and for applications ranging from medical diagnostics to see-through imaging. Although time domain emitters have the advantages of phase coherence and broad spectral range, the peak powers rarely exceed microwatts. Quantum cascade lasers can produce tens of milliwatts, but are complex with thousand of epitaxial layers. A much simpler approach is based on radiative transitions in neutral dopants and impurities in semiconductors. The dopants can be excited by an electrical current, or optically, and the THz emission occurs when the excited hydrogenic states relax toward the ground state. Both n-type and p-type dopants can be used for THz emission from many semiconductors including silicon. Unlike for conventional device applications, the dopants must not be thermally activated, however, which suggests deep dopant levels and/or low temperature operation. This application favors the wide bandgap semiconductors such as SiC and GaN, which can be incompletely activated even at room temperature, depending on the dopant. For example, electrically pumped THz emitters operating at temperatures over 250 K in pulse mode were

fabricated from nitrogen-doped SiC. The emission spectra had peaks from 5 to 12 THz (20 to 50 meV) that were attributed to electronic transitions of the nitrogen donors. These surface-emitting devices produced a peak power density at 77 K of 60 milliwatt/sq.-cm, which is suitable for a wide range of high power THz applications. We will report on the characteristics and limitations of dopant-based THz emitters from several semiconductor systems.

8846-14, Session 3

Broadband photonic terahertz-wave emitter based on planar-antenna-integrated UTC-PD *(Invited Paper)*

Hiroshi Ito, Kitasato Univ. (Japan); Toshihide Yoshimatsu, Nippon Telegraph and Telephone Corp. (Japan); Tadao Ishibashi, NTT Photonics Labs. (Japan)

Photomixing is a promising technique for generating continuous terahertz (THz) waves since it offers extremely-wide frequency tunability, very narrow line-width, and the capability of low-loss signal transmission through flexible optical fibers. Especially, the use of long-wavelength (1.55-um-band) light is practically important. The uni-traveling-carrier photodiode (UTC-PD) is a promising solution for such requirements. The UTC-PD has a unique mode of operation where only electrons are the active carriers. This is the key to achieving high speed and high saturation output current simultaneously.

To fully utilize the features of the UTC-PD for the THz-wave generation, monolithic integration of a proper planar antenna is indispensable. Among several antennas, the self-complementary (SC) antenna is one of the best solutions for the signal transmission over the wide-frequency-range from single device, because its input impedance is independent of the source frequency. We fabricated devices integrating several types of SC antennas, and assembled them in quasi-optical packages. Although all the modules exhibited broadband output characteristics up to 1.6 THz with similar output powers, the output characteristics at lower frequency side as well as their polarization characteristics were quite different. We could detect output powers from 30 GHz to 1.6 THz with almost constant polarization from a device integrating a novel compact planar antenna. Typical detected output powers were 120 uW at 200 GHz, 17 uW at 500 GHz, and 2.9 uW at 1 THz for a photocurrent of 10 mA with a bias voltage of only -0.6 V.

8846-44, Session 3

Semiconductor devices and electronics from microwaves to terahertz *(Invited Paper)*

Dimitris Pavlidis, Boston Univ. (United States)

Wide bandgap semiconductors, such as III-Nitrides and II-VIs, offer unique electronic and optical properties that make them suitable for a variety of applications ranging from communications to sensing. Components made with these materials operate from microwave-to millimeter-wave and THz frequencies. Signal generation and detection is particularly challenging at very high frequencies and new two- and three-terminal device approaches are being explored for this purpose. The talk will review various electronic device approaches, based on material, design, circuit implementation, processing and characterization considerations. These concepts pave the way to new families of components capable of responding to future electronic needs in the microwave to THz frequency regime.

8846-16, Session 4

Terahertz emission in polariton systems *(Invited Paper)*

Ivan A. Shelykh, Nanyang Technological Univ. (Singapore) and Univ. of Iceland (Iceland); Alexey V. Kavokin, Univ. of Southampton (United Kingdom)

We will consider several possible mechanisms of THz emission in polariton systems, namely:

1. We will show that planar semiconductor microcavities in the strong coupling regime can be used as sources of stimulated terahertz radiation. Emitted terahertz photons would have a frequency equal to the splitting of the cavity polariton modes. The optical transition between upper and lower polariton branches is allowed due to mixing of the upper polariton state with one of the excited exciton states and is stimulated in the polariton laser regime.

2. We will demonstrate that vertical cavity surface emitting terahertz lasers can be realized in conventional semiconductor microcavities with embedded quantum wells in the strong coupling regime. The cavity is to be pumped optically at half the frequency of the 2p exciton state. Once a threshold population of 2p excitons is achieved, a stimulated terahertz transition populates the lower exciton-polariton branch, and the cavity starts emitting laser light both in the optical and terahertz ranges. The lasing threshold is sensitive to the statistics of photons of the pumping light.

3. We will demonstrate the possibility of superradiant THz emission from dipolariton systems where resonant excitation of the cavity mode by a short pulse of light induces oscillations of the indirect exciton density with a characteristic frequency of Rabi flopping which generates . This results in oscillations of classical Hertz dipoles array which generate supperradiant emission on a terahertz (THz) frequency.

8846-17, Session 4

Highly efficient quantum dot-based photoconductive THz materials and devices *(Invited Paper)*

Ross R. Leyman, David J. Carnegie, Natalia Bazieva, Edik U. Rafailov, Univ. of Dundee (United Kingdom)

The THz optoelectronics field is now maturing and semiconductor-based THz devices are becoming more widely implemented as analytical tools in spectroscopy and imaging . Research into ultrafast semiconductor materials for THz devices is predominantly devoted to improving the optical-to-THz efficiency of photoconductive (PC) materials that generate THz signals when driven by suitable ultrafast coherent optical sources.

Materials traditionally used for this include low temperature-grown gallium arsenide (LT-GaAs) and LT-InGaAs for longer wavelength operation, and are used because the growth process integrates lattice defects and carrier trapping sites throughout the bulk, which act to shorten carrier lifetimes but also compromises carrier mobility and PC gain. We demonstrate here PC THz antenna devices comprising of GaAs/InAs quantum dot-based semiconductor structures, which utilise ultrafast carrier capturing offered by implanted InAs QDs to allow THz operation. This allows ultrafast optical pumping of the device with wavelengths absorbed by both/either the high quality GaAs crystal and/or InAs QDs, with high carrier mobility and almost arbitrarily short carrier lifetimes down to around 0.2 ps which is strongly determined by the pre-chosen QD layer periodicity .

We discuss such THz devices which exhibit optical-to-THz conversion efficiency around 5 times greater than commercial LT-GaAs-based devices.

8846-18, Session 4

Terahertz emitter based on dipolaritons

Oleksandr Kyriienko, Univ. of Iceland (Iceland) and Nanyang Technological Univ. (Singapore); Alexey V. Kavokin, Univ. of Southampton (United Kingdom) and St. Petersburg State Univ. (Russian Federation); Ivan A. Shelykh, Univ. of Iceland (Iceland) and Nanyang Technological Univ. (Singapore)

Dipolaritons are mixed light-matter quasiparticles formed in double quantum wells embedded into semiconductor microcavity. Here we study theoretically the effect of beats between dipolariton modes due to the tunnel coupling between direct and indirect excitons.

The model based on the Master equation for density matrix allows us to calculate dynamics of the system with accounting of decoherence effects using Lindblad approach. The combined tunnelling and cavity-exciton coupling effects result in Rabi flopping between two dipolariton modes and lead to harmonic oscillations of IX density. Since indirect excitons represent elementary dipoles, these density oscillations result in emission of THz frequency ranging from 1 to 4 THz. This mechanism of THz radiation is similar to downshift optical-to-THz frequency conversion used in laser driven terahertz emitters.

However, the system of dipolaritons has some important advantages over previously studied systems, namely: (1) the better tunability of the system allowing for fast modulation of the THz emission frequency; (2) improved spectral characteristics of THz signal which can be controlled using applied voltage and pumping conditions; (3) possibility to achieve a high output power as it is described below.

The essential difference of the generation scheme we propose from the previously studied schemes is in the use of the superradiance effect appearing due to the fact that Rabi oscillations in the dipolariton system are coherent. Rabi oscillations can be sustained by the cavity for several tens of picoseconds, which strongly improves the quantum efficiency of the emitter.

Bipolar THz-lasing structures based on InAs-GaSb coupled quantum wells as an alternative to intersubband lasing *(Invited Paper)*

Leonid D. Shvartsman, Boris Laikhtman, The Hebrew Univ. of Jerusalem (Israel)

Development of compact low-cost sources of a coherent radiation with a high efficiency in the range of several THz remains one of the key challenges of the modern security technologies. In spite of rather impressive achievements in intersubband quantum cascade lasers their current parameters are still far from the needs of practical implementation. We present here a bird-eye view on the current state of the field. We compare theoretical prospects of the optimal gain of lasers in the range of few THz for two cases: intersubband GaAs-based quantum cascade lasers and interband laser based on coupled quantum wells InAs-GaSb. We show that the last case promises the gain that could be three orders of magnitude higher.

Our methodology of such a comparison of two different systems that is reduced to the following. The most typical design of four-five subband multi-well GaAs-based QCL is compared with a typical InAs-GaSb coupled quantum well laser (CQWL) operating in the same frequency range. The detailed density matrix based calculation shows that the maximal possible gain for CQWL can be three orders of magnitude higher than for QCL while from the technological point of view QCLs , of course, still look much more attractive.

8846-20, Session 4

Tunable THz source using small parallel-connected superconducting tunnel junctions

Faouzi Boussaha, Alexandre Feret, Christine Chaumont, Observatoire de Paris (France); Lionel Loukitch, Institut National des Sciences Appliquées (France); Thibaut Vacelet, Observatoire de Paris (France)

We report on tunable submillimeter-wave radiation sources based on micrometer-sized superconducting tunnel junction arrays optimized within a bandwidth of 350-520 GHz. The arrays consist of 10, 20 and 40 Superconductor-Insulator-Superconductor (SIS) parallel-connected Nb/AlOx/Nb junctions embedded in superconducting microstrip lines. A SIS twin-junction is integrated along with each array to detect output signals. The pumped detector's I-V characteristic exhibits clearly photon-assisted quasiparticule steps when the arrays are biased upon corresponding Josephson resonances ranging from 370 to 520 GHz. We will present optimization and measurement results.

8846-21, Session 5

Nanotransistor based THz plasma detectors: low tempeatures, graphene, linearity, and circular polarisation studies *(Invited Paper)*

Wojciech Knap, Univ. Montpellier 2 (France)

Nanometer size field effect transistors can operate as efficient broadband terahertz detectors, far beyond their fundamental cut-of frequencies[1]. We present an overview of some important and recent results concerning the physics of THz rectification by nanometer scale field effect transistors. We report on temperature [2], power and polarization sensitivity studies [3] of these detectors.We report also on measurements of THz rectification by graphene field effect transistors[4] and they applications for THz communication[5].

Field effect transistor as detector of THz radiation hélicity

Konstantin S. Romanov, Univ. Montpellier 2 (France); Christoph Drexler, Univ. Regensburg (Germany); Nina Diakonova, Univ. Montpellier 2 (France); Peter Olbrich, Johannes Karch, Michael Schafberger, Univ. Regensburg (Germany); Yuri A. Mityagin, P.N. Lebedev Physical Institute (Russian Federation); Dmytro B. But, Univ. Montpellier 2 (France); Oleg A. Klimenko, P.N. Lebedev Physical Institute (Russian Federation); Frederic Teppe, Wojtek Knap, Univ. Montpellier 2 (France); Sergey D. Ganichev, Univ. Regensburg (Germany); Mikhail I. Dyakonov, Univ. Montpellier 2 (France)

Field Effect Transistors (FET) have been demonstrated as promising detectors of THz radiation. Here we report on the experimentally observed and theoretically studied helicity dependent photoresponse of FETs.

We studied commercially available GaAs/AlGaAs HEMTs. For optical excitation we used molecular lasers providing single line tuneable radiation in the frequency range of f = 0.6 - 2.5 THz. Transistors were irradiated by elliptically, circularly, or linearly polarized radiation at normal incidence. Measurements were performed at room temperature.

We observed that with the increase of radiation frequency, the magnitude of the maximum of the response decreases, and at high frequencies, the signal switches its polarity at a certain gate bias. The photoresponse of FET to circularly polarized radiation strongly depended on the helicity of radiation. At some gate biases, the photoresponse even changed its sign with the switch from the right- to the left-handed circular polarization.

The phenomenon is interpreted in the frame of the generalized Dyakonov-Shur model. It results from the interference of plasma oscillations inside the FET channel. These oscillations are induced by antennas sensitive to different linear polarizations. The calculation shows that the helicity dependent response strongly depends on the length of FET and impedances of antennas. The obtained dependencies of photoresponse voltage on gate bias voltage qualitatively describe the experimental data. The results provide the basis for a new sensitive, all-electric, room-temperature and fast (better than 1 ns) characterisation of all polarization parameters of terahertz radiation.

8846-25, Session 6

Antenna-coupled microbolometer based uncooled focal plane array and camera for 2D real-time terahertz imaging *(Invited Paper)*

François Simoens, Jérome Meilhan, CEA-LETI (France)

CEA-Leti relied on its 20 year old know-how in thermal infrared bolometer to develop large monolithic focal plane arrays optimized for 2D real-time imaging in the terahertz range. A dedicated innovative bolometric pixel has been designed with an ongoing concern to achieve low cost devices both in fabrication and in use thanks to standard CMOS microelectronic processes and room temperature operation.

Specific structures of antennas and a resonant quarter-wavelength cavity are associated to a silicon bolometer microbridge: this architecture offers better than 10pW power detection threshold on the whole THz range by proper tailoring of the antennas while keeping the technological stack unchanged.

First prototypes of imaging arrays have been designed and manufactured for optimized sensing in the 2.5THz vicinity where THz quantum cascade lasers are delivering high optical power.

This paper first reports the latest results of performance characterizations where metrology conditions have been carefully carried out.

Then several tested implementations for real-time imaging applications are presented. In particular terahertz spectro-imaging techniques have been applied to concealed sugar pellets analysis with the use of a complete system developed by our institute. Real-time reflectance imaging of large surface of hidden objects has been demonstrated. High quality images of broadband THz beams delivered by a TDS system in the 0.1-2 THz range have shown the high interest of real-time 2D beam profiling.

Then perspectives of camera integration are discussed.

8846-26, Session 6

Discrete spectrum terahertz imaging using bow-tie diodes: optimized antenna designs and arrays

Gintaras Valu?is, Linas Minkevicius, Karolis Madeikis, Irmantas Ka?alynas, Rimvydas Venckevi?ius, Dalius Seliuta, Vincas Tamo?i?nas, Ctr. for Physical Sciences and Technology (Lithuania)

Discrete spectrum terahertz imaging using bow-tie diodes: optimized antenna designs and arrays

Linas Minkevi?ius, Karolis Madeikis, Irmantas Ka?alynas, Rimvydas Venckevi?ius, Dalius Seliuta, Vincas Tamo?i?nas and Gintaras Valu?is

Center for Physical Science and Technology, A. Go?tauto 11, 01108 Vilnius, Lithuania

Terahertz (THz) imaging is a powerful tool to observe packaged objects in various THz-radiation transparent materials like paper cartoon or plastic boxes. In order to indentify materials one needs to resolve spectral signatures at certain frequencies and improve recording system using multipixels arrays.

Recently, we have demonstrated that so-called InGaAs bow-tie diodes can successfully be used for terahertz direct and heterodyne imaging [1]. Employing broadband features of the device, spectra and images of plastic explosive simulators prepared from tartaric acid and sucrose were recorded within the frequency range of 0.585–2.52 THz [2].

In this work, we concentrate ourselves in optimization of InGaAs diodes operation at certain frequencies and demonstration of the bow-tie arrays performance.

Optimization routes were demonstrated using simulations based on 3D finite-difference time-domain method, calculating electromagnetic field amplitude ratio distribution in detector plane. Three types of designs – bow-tie diode itself, log-periodic antenna and log-periodic antenna coupled with the bow-tie diode were analyzed at frequencies of 0.3 THz and 0.6 THz. Enhancement of sensitivity nearly one order of magnitude is observed.

Terahertz imaging using multi-pixel arrays is demonstrated. Options for further improvements are discussed, implementation for real-time imaging applications is considered.

8846-27, Session 6

Possibility of the passive THz camera using for a temperature difference observing of objects, placed inside the human body

Vyacheslav A. Trofimov, Vladislav V. Trofimov, Lomonosov Moscow State Univ. (Russian Federation)

We demonstrate the possibility of using of a passive THz camera for a temperature difference observing in the human skin if this difference is caused by different temperatures inside the body. We discuss two physical experiments, in which a person drinks hot and cold water. After computer processing of images captured by passive THz camera TS4 we may see the pronounced temperature trace on skin of the human body. We illustrate this phenomenon by a series of images captured by passive THz camera in real time.

As we believe, these experiments allow to increase field of passive THz camera using for the detection of objects concealed in the human body because the difference in temperature between object and parts of human body will be reflected on the human skin. However, modern passive THz cameras have not enough resolution in temperature to see this difference. That is why, we use computer processing to enhancethe camera resolution for this application.

We discuss also other modern problems of the THz passive camera using.

8846-28, Session 6

Experimental beam profiling and modeling of a terahertz beam generated from a 2-color air plasma

Pernille K. Klarskov, Andrew C. Strikwerda, Peter U. Jepsen, Technical Univ. of Denmark (Denmark)

As the steady advance of terahertz (THz) technology continues from research towards applied science, it is increasingly important to fully specify all characteristics of a given THz system. One of the more common THz generation techniques, due to its incredibly broad bandwidth, is that of nonlinear generation in a two-color air plasma. However, even though this technique has been widely used for several years, there have been few studies of the beam profile, and it was only published recently that the generated THz radiation propagates in a conical-like pattern due to an off-axis phase matching condition [You et al., Physical Review Letters, 109, 183902 (2012)]. To appropriately perform location dependent measurements such as imaging and z-scans, it is imperative to account for the spatially variant form of the THz waveform. Furthermore, it is beneficial to represent such an emission pattern in terms of well-understood propagating beam profiles.

Here we present our most recent results characterizing THz beams generated by two-color air plasmas. Using a THz camera (NEC IRV-T0831) and a pair of off-axis paraboloids, we experimentally measure the location dependent THz profile as it passes through a beam waist, similar to typical THz-TDS spectroscopy setups. We demonstrate that as the THz transient propagates through the beam waist, it tightens from the generated conical profile to a spot-like focus and eventually evolves back to a ring. This behavior is characteristic of Bessel-Gauss beams, and we qualitatively support this interpretation with numerical simulations.

8846-29, Session 7

Holography and phase retrieval in terahertz imaging *(Invited Paper)*

Nikolay V. Petrov, National Research Univ. of Information Technologies, Mechanics and Optics (Russian Federation); Andrei A. Gorodetsky, Foundation for Research and Technology-Hellas (Greece); Victor G. Bespalov, National Research Univ. of Information Technologies, Mechanics and Optics (Russian Federation)

In this talk we present review and latest results obtained in the scope of terahertz holographic and other methods for phase retrieval in terahertz imaging. Not only accurate change of amplitude, but also rigorous phase retrieval is essential for precise calculation of optical parameters of the samples in terahertz range.

Pulse terahertz holography introduced some years ago shows itself as perfect method for overall-object phase retrieval technique, but in the same time it allows measurement with low signal to noise that leads to less precise derivation of sample optical parameters. And certainly just point-by-point terahertz time-domain spectroscopy provides the most precise information of sample phase, but it is rather time consuming and has low spatial resolution as well.

The other possible way assumes, in contrary to pulse terahertz holography and spectroscopy, using narrowband CW terahertz source, which tunability might also make the measurement process easier. And diffraction patterns registered with microbolometer array or any other terahertz intensity sensor placed at several different distances from the object and/or taken for several different terahertz frequencies are used for phase retrieval in this case.

We present both numerical predictions and experimental results for the proposed methods, estimate the achievable spatial and other limits of the techniques, compare them to the others used in different spectral ranges and discuss future steps that are to be done in the scope of further improvements of existing terahertzphase retrieval techniques and possible new ways of full terahertz wavefront registration and use.

8846-30, Session 7

3D terahertz synthetic aperture imaging of objects with arbitrary boundaries

Gabriel P. Kniffin, Lisa M. Zurk, Scott Schecklman, Portland State Univ. (United States); Samuel C. Henry, Univ. of Washington (United States)

Terahertz (THz) imaging has shown promise for nondestructive evaluation (NDE) of a wide variety of manufactured products including integrated circuits and pharmaceutical tablets. Its ability to penetrate many non-polar dielectrics allows tomographic imaging of an object's 3D structure. In this work, we present advanced, physics-based THz synthetic aperture processing techniques which allow the 3D imaging and characterization of objects with one or more irregular boundaries.

In NDE applications, the material properties of the target(s) and background media are often well-known a priori and the objective is to identify the presence and/or 3D location of structures or defects within. The authors' earlier work demonstrated the ability to produce accurate 3D images of conductive targets embedded within a High Density Polyethelene (HDPE) background. That work assumed a priori knowledge of the refractive index of the HDPE as well as the physical location of the planar air-HDPE boundary. However, many objects of interest exhibit non-planar surfaces, such as varying degrees of curvature over the extent of the surface. Objects under test may also contain multiple stratified layers with differing refractive indices. Irregular boundaries between layers introduce refraction effects that distort 3D tomographic images.

In this work, a split-step Fourier migration method is applied to THz synthetic aperture processing to correct the artifacts introduced by irregular boundaries. The algorithm accurately detects the 3D location of the boundaries and provides high-resolution tomographic images of an object's internal structure. These techniques are demonstrated with measurements from a THz time-domain imaging system.

8846-31, Session 7

3D terahertz imaging *(Invited Paper)*

Patrick Mounaix, Univ. Bordeaux 1 (France)

Terahertz radiations can be seen as electromagnetic waves in the spectral range going from 0.3 to 10 THz. Low energy interaction of a wide range of materials can thus be studied by these waves and new data can potentially be retrieved to complete the knowledge of material. Terahertz technology has been making rapid progress following recent advances in femtosecond lasers and ultrafast semiconductor sources emitting in the THz frequency range. One of the most attractive properties of THz waves is their ability to pass through a wide variety of materials. They can be used to control or analyze through many types of packaging material. Moreover, the interaction with THz waves is non destructive, and thus these radiations can be used to probe fragile biological materials not only for basic research, but also for applications in a wide variety of fields.

More recently, the inventory of applications has increased to include, quality control, non destructive testing, and spectroscopic characterization .Two-dimensional THz transmission images were first acquired in 1995 by Hu and Nuss and sounded the beginning of 2D and 3D imaging science. Then a lot of research developments in terahertz imaging have made use of terahertz time-domain spectroscopy but also with numerous new efficient sources and detectors for continuous-wave terahertz radiation.

In the literature a number of methods for 3D imaging with THz radiation have been proposed and demonstrated. We will describe briefly different physical techniques capable to extract 3D information and we will analyze advantages and drawbacks of each method.

8846-32, Session 7

Terahertz imaging for medical applications *(Invited Paper)*

Joo-Hiuk Son, The Univ. of Seoul (Korea, Republic of)

Terahertz (THz) imaging is a promising modality for medical diagnosis because it is non-ionizing, sensitive to water molecules, and capable of spectroscopic analysis. In this presentation, various examples of medical imaging using THz radiation will be reviewed. First, the feasibility of THz dynamic imaging for visualizing serial changes in the distribution and penetration of a topical transdermal drug is demonstrated and compared with the Franz cell diffusion test. Secondly, some cases of cancer imaging using THz radiation are shown, which include brain tumor and oral melanoma. The THz imaging results are also compared with magnetic resonance (MR) imaging and conventional histology. Thirdly, the principle of terahertz molecular imaging (TMI) technique using nanoparticles is explained and the factors related to molecular imaging, such as sensitivity, resolution, and quantification property are characterized. The technique is applied to the diagnosis of cancerous tumors targeted with phase-conjugated nanoparticles and the distribution measurement of nanoparticle drug delivery to organs in vivo and ex vivo. Lastly, THz imaging is also utilized to analyze blood non-invasively. The THz complex optical constants of blood and its constituents such as water, plasma, and red blood cells (RBCs) are measured and used to extract the concentrations of RBCs. In conclusion, the author believes that there are some points where terahertz imaging can contribute to the real-world medicine.

8846-33, Session 8

The stable and intense broadband THz coherent synchrotron source at SOLEIL: performances and research program *(Invited Paper)*

Pascale Roy, Synchrotron SOLEIL (France)

The recent years have seen a significant development in Terahertz radiation production: moderate intensity broadband sources and higher power narrow band tunable sources. Although both types of sources allow significant breakthrough, only Coherent Synchrotron Radiation (CSR) combines the two advantages, providing a broadband and quite intense radiation in the THz domain. CSR occurs in electron storage rings when the wavefronts emitted by electrons within a bunch superimpose at equal phase. The resulting source power has a quadratic dependence to the number of electrons per bunch (typically 109) and can therefore reach several mW. The spectral range depends on the longitudinal shape of the electron bunch, but can be widened towards a few THz by reducing the bunch length. A third figure of merit, the source stability, which allows unprecedented signal to noise values and absolute intensity measurement is also clearly a strong point for CSR.

At the AILES beamline of SOLEIL synchrotron (France) the combined brilliance, stability and wide range (0.2-2 THz) achieved through this method has lead to an optimal use of FTIR in the THz range, hitherto unusable for demanding experiments. In particular, we are currently performing high resolution rotational studies of transient or reactive species, for which reducing the measurement duration is a prerequisite. The present measuring mode also allows an extension to the THz domain of near field subwavelength microspectrometry.

8846-34, Session 8

Probing of local electron states in Pb1-xSnxTe(In) narrow-gap semiconductors using laser terahertz radiation

Vladimir Chernichkin, Ludmila I. Ryabova, Lomonosov Moscow State Univ. (Russian Federation); Andrey V. Nicorici, Institute of Applied Physics (Moldova); Sergey G. Danilov, Univ. Regensburg (Germany); Dmitry R. Khokhlov, Lomonosov Moscow State Univ. (Russian Federation)

A new type of semiconductor local states is revealed in lead-tin telluride solid solutions doped with indium. The energy position of these states is not linked to any specific location in the semiconductor energy spectrum, but follows the quasiFermi level position, which may be tuned by photoexcitation. The binding energy of these states is less than 10 meV providing appearance of photoresponse at wavelengths exceeding 100 ?m. This conclusion is based on the results of experiments that use illumination of the samples by 100 ns – long pulses of a terahertz laser with the wavelengths of 90, 148 and 280 ?m.

We investigated photoconductivity in single crystals of Pb1-xSnxTe(In) with x varied within 0.22-0.29, and in highly degenerated polycrystalline PbTe(In) films. The persistent photoconductivity induced by the background radiation has resulted in generation of long-lived non-equilibrium electrons at low temperatures and, consequently, to formation of a quasiFermi level in the conduction band. The distance between the quasiFermi level and conduction band bottom depended on the alloy composition and reached its maximum of ~ 100 meV in PbTe(In) films. Tuning of the quasiFermi level position in PbTe(In) by means of an additional optical pumping allowed reducing conductivity by 20% of its initial value and to push the quasiFermi level position up by ~ 20 meV. No change of the relative photoresponse was observed for all of the laser wavelengths. It means that the local electron states remain in the close vicinity of the quasiFermi level even after it moves to another position.

8846-35, Session 8

Remote detection of nuclear materials using air breakdown ionization signatures *(Invited Paper)*

Phillip A. Sprangle, Univ. of Maryland, College Park (United States)

This paper presents a new concept for the remote detection of nuclear materials. This novel and advantageous detection method is based on air breakdown signatures in the vicinity of nuclear material and can enable stand-off detection at distances far greater than 100 m. Radioactive materials emit gamma rays which ionize the surrounding air. The free electrons produced by the gamma rays rapidly attach to oxygen molecules forming ions. In the vicinity of nuclear materials the density of ions and electrons is highly elevated compared to background levels. The enhanced levels of oxygen ions, which have a very low ionization potential, are a source of free electrons for inducing avalanche air breakdown. Air breakdown, i.e., spark formation, is driven remotely by high power THz or laser radiation or depending on stand-off distances and atmospheric conditions. The characteristics of the induced spark, e.g., breakdown rate, timing delay, duration and spectrum, are a direct signature of the presence of radioactivity. The rapid rise in electron density in the spark induces a detectable frequency modulation on a probe laser pulse which is also a detection signature.

Effective criterion for the detection and identification of explosive using the spectral dynamics analysis of THz reflected signal in real time

Vyacheslav A. Trofimov, Nikolay V. Peskov, Lomonosov Moscow State Univ. (Russian Federation)

One of the problems, arising in using of Time-Domain THz spectroscopy for the security, consists in developing of probability assessment criterion

for the detection and identification of the explosive and drugs. In present report we propose new effective criterion for finding the substance at using the reflected THz signal. This criterion consists of two steps. First step consists in preliminary definition of appropriate range of THz spectra of considered substances to detect the difference in spectral lines dynamics. The second step is a use of proposed integral estimation for the assessment of presence of required substance.

This approach was applied for distinguishing the substance with similar properties in the mixture. It is very important to stress that this criterion may be used in real-time.

8846-37, Session 8

THz intervalence antipolaritons

Mauro F. Fernandes Pereira Jr., Inuwa A. Faragai, Sheffield Hallam Univ. (United Kingdom)

In this paper we predict how a valence band excitation couples with TE-polarized THz radiation in a microcavity. This configuration would allow easier measurements of polaritons [1] and antipolaritons [2] without the need to grow the resonator in a slanted prism, as in usual TM mode, conduction band realizations. A Nonequilibrium Many Body approach delivering an optical response beyond the Hartree-Fock approximation allows the study of multiple transitions and an interesting picture of interacting polaritons and antipolaritons develops due to the coexistence of gain and cross absorption to higher subbands. The combination of bandnonparabolicity and nonequilibrium effects beyond the Hatree-Fock approximation plus microcavity coupling lead to further branches in the polariton spectrum that would not be expected with free carriers.

Integrated diode technology for THz applications *(Invited Paper)*

Jan Stake, Huan Zhao, Vladimir Drakinskiy, Tomas Bryllert, Aleksandra Malko, Johanna Hanning, Aik Yean Tang, Chalmers Univ. of Technology (Sweden); Peter Sobis, Omnisys Instruments AB (Sweden); Robin Dahlbäck, Josip Vukusic, Chalmers Univ. of Technology (Sweden)

This paper provides an overview of research on terahertz integrated diodes and circuits carried out at Chalmers, Göteborg, Sweden. We will present progress on integration techniques for HBV multipliers and Schottky diode mixers and multipliers, including epitaxial transfer of III-Vs and heterogeneous integration on silicon. Moreover, we will present progress on THz device modelling and results from S-parameter characterization of on-chip components at terahertz frequencies. Finally, performance of mixer and multiplier demonstrators based on in-house technology will be presented.

8846-24, Session PMon

The dynamic range of THz broadband FET detectors

Dmytro B. But, Univ. Montpellier 2 (France); Oleksiy Drachenko, Forschungszentrum Rossendorf (Germany); Nina V. Dyakonova, Univ. Montpellier 2 (France); Alexey Gutin, Rensselaer Polytechnic Institute (United States); Christoph Drexler, Sergey D. Ganichev, Univ. Regensburg (Germany); Wojciech Knap, Univ. Montpellier 2 (France)

The goal of this work was to study the capability of THz Field effect transistor (FET) detectors to measure high power radiation at frequencies from 0.3 to 3 THz and to determine the limits of linear detection. FETs are promising detectors of THz radiation. They have high responsivity, low noise equivalent power and fast response time.

We studied several type of HEMTs at the room temperature. To provide a wide range of incident THz radiation intensities we used different types of sources: i)continuos-wave: backward oscillators and CO2 pumped methanol laser ii) pulsed: NH3, D2O, and CH3F lasers and iii) the free electron laser (FEL) with pulses regime.

The nonlinear detection of THz radiation in FET had been predicted theoretically. According to the model the detection signal versus the radiation power should increase linearly changing gradually into square root like dependence. The linear effect and sublinear saturation were observed at different radiation frequencies in our experiments. In experiments with THz gas lasers we observed the linear dependence (up to about 1 kW/cm^2) followed by sublinear one in the range up to several I MW/cm^2. With FEL source at 2.11 THz with to extremely short pulses the photoresponse behaves differently: it increases close to the square of the power, saturates and then decreases slowly at the highest power levels.

We discuss the unusual behavior observed at high intensity experiments considering several phenomena: i) electron heating ii) impact ionisation or iii) response time effects related to extremely short pulses.

8846-39, Session PMon

The dependence of terahertz signal and third harmonic amplitudes on mutual polarization of two-color pump components under optical breakdown of air

Alexander Ushakov, Roman Volkov, Andrey Savel'ev, Lomonosov Moscow State Univ. (Russian Federation); Pavel Chizhov, Vladimir Bukin, Sergey V. Garnov, A. M. Prokhorov General Physics Institute (Russian Federation)

One of the methods to receive electromagnetic radiation in the terahertz range is the laser induced optical breakdown of gases (for instance, in the air under atmospheric pressure). In this scheme low-frequency radiation is created by the optical rectification process upon interaction of the femtosecond laser radiation at fundamental frequency with its second harmonic in a medium with cubic nonlinearity: ?_THz=2?-?-?. This process occurs due to a mechanism called "transient photocurrent" which takes place under ionization of air by the two-color field. This model provides a different dependence of the amplitude of terahertz signal than predicted by the structure of tensor of cubic nonlinearity. At the same time it is known that air breakdown is accompanied by the generation of the third harmonic. In this paper we decided to measure the dependence of the signal of the third harmonic and terahertz radiation on the mutual polarization of the first and second harmonic to compare the mechanisms of their generation. For this purpose we used the output radiation of laser system Spitfire pro with the following parameters: pulse duration 35 fs, central wavelength 800nm, repetition rate 1kHz, energy of the first and second harmonic are 2mJ and 240?J respectively. The radiation was focused by parabolic mirror with focal length 7,5 cm in air. The energy of terahertz and third harmonic radiation was measured by Holey cell and photomultiplier respectively.

8846-40, Session PMon

Investigations of acoustic wood for luthiers using terahertz imaging

Dominique Coquillat, Univ. Montpellier 2 (France) and Ctr. National de la Recherche Scientifique (France); Julien Moulin, Univ. Montpellier 2 (France); Jean-Paul Brouillet, Univ. Montpellier 2 (France) and Univ. Montpellier 1 (France); Nina V. Dyakonova, Frederic Teppe, Wojciech Knap, Univ. Montpellier 2 (France) and Ctr. National de la Recherche Scientifique (France)

New developments in terahertz technologies are opening the doors to sensing and imaging in industry. Terahertz imaging can be employed as a non-destructive evaluation tool of acoustic wood. Often difficult to detect visually, severe runout – that refers to the orientation of the wood cells not completely parallel to the board surface of a string instrument – can be detrimental to strength and sound vibrational characteristics. Most luthiers try then to avoid runout if possible. Terahertz imaging enables inspection not only for evidence of cracks, voids, defects, worm damage, but also for runout.

In the framework of the LABEX NUMEV project, terahertz imaging has been employed as a non-destructive evaluation tool of acoustic wood. The birefringence properties at terahertz frequencies associated with the fiber orientation are used to investigate wood runout.

Using Silicon MOSFET as sensitive, compact and cost-efficient terahertz detector, we have observed that there is a notable difference between the birefringence of the four acoustic wood species studied: western red cedar (Thuya plicata), spanish cedar (Cedrela odorata), indian rosewood (Dalbergia latifolia), and ebony (Diospyros sp), used for the sound board, the neck, the back and sides, and the fingerboard, respectively. Among them, the softwood red cedar has a strong anisotropy, whereas rosewood is very inhomogeneous spatially in density. The terahertz imaging in transmission mode measured as a function of both incidence and azimuthal angles, proposed here, can be relevant for luthiers to select acoustic wood without runout or to observe how wood has warped overtime.

8846-41, Session PMon

Polymer based single mode optical waveguide for spectroscopy applications

Maurine Malak, Ecole Polytechnique Fédérale de Lausanne (Switzerland); Konstantins Jefimovs, EMPA (Switzerland); Hans Peter Herzig, Toralf Scharf, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Being low cost, light-weight, non-wearable, flexible and easily shaped, polymer materials acquired a high interest and became largely deployed in the microfabrication of passive optical devices. Oppositely to silicon, polymeric materials offer a transparency for light in the near infrared range.

For these reasons, we developed a compact 2-D low loss single mode optical waveguide fabricated with EPO materials. The waveguide geometry is of square shape, its refractive index distribution has a step-index profile and it is buried between two EPO-clad layers. Realized by polymer deposition, the guide consists mainly, of a stack of EPO-clad/EPO-core/EPO-clad layers sandwiched between two glass substrates having a thickness of 0.5 mm. The refractive index difference between the EPO-layers is 2.5x10-3. The waveguide dimensions are 3x2.2?m2. A cleaved single mode optical fiber, operating in the visible range (658 nm), is used to perform optical characterizations, double side polished structure exhibits an insertion loss of 2.6 dB, a numerical aperture of 0.25 and a cross-talk level of 15 dB for waveguides spaced apart by 150 ?m.

Intended for spectroscopy applications, the final demonstrator embeds a high reflectance mirror at the waveguide exit. Then, a standing wave interference pattern is build-up inside the optical waveguide. Sampling of the pattern using an array of nano-antennas deposited on top of the waveguide, yields information about the spatial distribution of the interferogram. Applying Fast Fourier Transform, the spectral content of the signal can be deduced and the prototype demonstrates a strong potential for applications of high performance spectroscopy.

Transient mobility and photoconductive terahertz emission with GaP

Christopher M. Collier, Brandon Born, Xian Jin, Timothy M. Westgate, Max Bethune-Waddell, Mark H. Bergen, Jonathan F. Holzman, UBC Okanagan (Canada)

Wide-bandgap semiconductors are appealing materials for photonic systems seeking high electric field breakdown strengths, and photoconductive terahertz (THz) generation systems are a major example of this. Especially large THz powers can be achieved by biasing with high electric fields. Unfortunately, standard wide-bandgap semiconductors also have slow electron-hole recombination rates, and the corresponding nanosecond/microsecond carrier lifetimes can limit the THz system recovery. With this in mind, there is a concentrated effort to develop wide-bandgap semiconductors with ultrafast recovery rates. Such materials would provide high-power THz generation with picosecond recovery times.

In this work, GaP is investigated for use in photoconductive THz generation. The atypical bandstructure of GaP, with a central high-mobility Gamma valley being higher than the low-mobility L and X sidevalleys, is exploited to establish a transient state of high-mobility photoconduction. The subsequent scattering and relaxation of hot electrons into and within the lower-mobility sidevalleys leaves the material in a low-conduction state. Experimental and theoretical studies are carried out to show that this ultrafast transient mobility process, occurring over 800 fs, can create broadband THz pulses with reduced recovery times (and low leakage currents). The impacts of these findings are discussed for efficient and portable next-generation THz systems.

8846-43, Session PMon

Microstructure analysis of confined liquids with terahertz time-domain spectroscopy

Nicholas Y. Tan, Lynn F. Gladden, Axel Zeitler, Univ. of Cambridge (United Kingdom)

Due to the utility of porous materials as heterogeneous catalysts in chemical processes, the interactions between catalysts and the reactants at interfaces have been extensively studied with methods such as nuclear magnetic resonance (NMR) and electron paramagnetic resonance (EPR). Recent experimental work by Havenith et al. showed that terahertz time-domain spectroscopy (THz-TDS) was a useful tool in characterising adsorbed water in MOF-5. The authors found non-linear frequency dependent changes in the THz spectra, which was indicative of coupling between the lattice modes of MOF-5 and network motions of the bound water. Far-infrared spectroscopy has also been used to probe confined water in organic porous material. These measurements showed differences in the dynamics of water confined in small pores compared to water confined in large pores.

We present the terahertz absorption spectra of isopropanol and water confined in several porous catalysts: silicates, metal-organic frameworks and porous organic cages. The spectra are acquired using THz-TDS over the frequency range of 0.4 - 1.5 THz. The dielectric spectra are also presented, which cover both fast and slow liquid relaxation processes. These spectra are compared against bulk liquids to determine the effects of confinement.

The absorption spectra exhibit clear differences with varying levels of liquid loading. This is indicative of differences in the interfacial interactions between liquids and catalysts. In addition, significant differences were observed between the spectra of confined liquids and the bulk liquids, which clearly highlight the effect of confinement on the structuring of these liquids.

Conference 8847: Photonic Fiber and Crystal Devices: Advances in Materials and Innovations in Device Applications VII

Sunday - Monday 25–26 August 2013

Part of Proceedings of SPIE Vol. 8847 Photonic Fiber and Crystal Devices: Advances in Materials and Innovations in Device Applications VII

8847-1, Session 1

Double pulse laser deposition of polymer nanocomposite: NaYF4:Tm3+,Yb3+ films for optical sensors and light emitting applications *(Invited Paper)*

Abdalla M. Darwish, Michael T. Sagapolutele, Simeon Wilson, Dillard Univ. (United States); Sergey S. Sarkisov Sr., SSS Optical Technologies, LLC (United States); L. Darayas N. Patel, Oakwood Univ. (United States)

The main objective of this paper is to demonstrate the feasibility of producing operationally Nanocomposite polymeric thin films for sensor and light emitting applications using the innovative modified double pulsed laser deposition (DPLD) technique. The existing PLD vacuum chamber was modified to accommodate multiple wavelength laser beams for in-situ-double-ablation/Deposition (DPLD) of multiple targets of host and dopants. Special design was made for cooling of the target to the threshold of the polymer ablation without interrupting the continuity of the ablation process. Multi-layered of nanocomposites of acrylic polymers and nanoparticles of NaYF4:Tm3+,Yb3+ are fabricated using ultra-violet (UV) radiation (355 nm) ablating polymer targets and near-infra-red (near-IR) radiation (1064 nm) ablating inorganic targets. The films were characterized using the reflected high energy electron diffraction (RHEED), XRD , XRF, AFM, and FTIR absorption spectroscopy and tested as possible chemical sensors and light emitters.

8847-2, Session 1

Improved SiPM device performance by introduction of a new manufacturing technology

Florian Wiest, Peter Iskra, Natsuki Miyakawa, KETEK GmbH (Germany); Thomas R. Ganka, Christoph Dietzinger, Univ. de Bundeswehr (Germany); Alicia Márquez Seco, KETEK GmbH (Germany)

Silicon photomultipliers (SiPMs) are intensely evaluated as a potential replacement of photomultiplier vacuum tubes for several applications. Essential key features are the photon detection efficiency, the dark count rate, the optical crosstalk and the scalability of the active area.

In order to achieve considerable improvements of these parameters, KETEK has introduced a new manufacturing technology based on 200 mm wafers and 0.35 µm stepper lithography. Important aspects of the well-established and for many years optimized KETEK Silicon Drift Detector technology could be transferred to the SiPM process.

Main items of the new technology are a narrow vertical trench around the individual microcells and an impurity getter: the first reduces the optical cross talk and the second the dark count rate by factor two, whereby the potential of this technology is still not maxed out.

A further aspect of the new technology is a low parasitic RC-value device concept: The reduction of parasitic RC-values is targeted on a scalability refinement of SiPM devices which is mandatory for active areas above 10 mm2.

Finally the geometrical fill factor and the light entrance window of the KETEK device has been further improved for which reason a 50 µm cell pitch device with a photon detection efficiency of 60% in the blue range will be presented.

Beyond that the SiPM devices show an extremely low temperature coefficient of the gain. This is due to an operation at very high overvoltage along with a low temperature coefficient of the break down voltage.

8847-3, Session 1

Colorless chalco-halide Ga2S3-GeS2-CsCl glasses as new optical material

Yannick Ledemi, Mohammed El Amraoui, Younes Messaddeq, Ctr. d'optique, photonique et laser (Canada)

Colorless sulfide glasses can be obtained by selecting appropriately the composition within the Ga2S3-GeS2-CsCl pseudo-ternary glass system. The addition of electronegative chlorine ions into the sulfide glassy network results in a widening of its optical bandgap without altering its infrared transparency. Glasses transparent from the near UV (380 nm) up to the middle infrared (11.5 ?m) are thus achievable. Such extended infrared transmission for a colorless glass is the widest among the known heavy metal oxide and fluoride glasses, e.g. fluoroindate glasses are transparent from 350 nm up to 8-9 ?m. We present in this work our recent progress on the preparation of this chloro-sulfide glass of high optical quality. Efforts have been devoted in a first step to reduce the content of extrinsic impurities such as OH, SH and H2O. In a second step, protective coatings have been deposited on polished glass samples to improve their chemical durability and assess their potential for practical applications. Large improvement of both optical quality, in terms of transmission spectrum flattening, and chemical durability were achieved. Finally, the high thermal stability against crystallization of this glass shows a high potential for lens molding and applications in multispectral imaging.

8847-4, Session 1

Fundamental studies on the correlation between antimony film properties and alkali-antimonide photocathode performance

Junqi Xie, Marcel Demarteau, Argonne National Lab. (United States); Henry J. Frisch, The Univ. of Chicago (United States); Edward A. May Jr., Robert Wagner, Jeffrey Williams, Argonne National Lab. (United States)

Photomultiplier tubes (PMTs), used as photodetectors, have many applications in fields such as medical diagnosis, chemical analysis, industrial measurement and scientific research. As an essential component of PMT, photocathode converts incoming photons into free electrons for output signal detection. The quality and performance of photocathode strongly determines the detection efficiency of a PMT. Currently, alkali antimonide compounds (Na-K-Cs-Sb) are the most widely used photocathode materials. Among most of the alkali antimonide photocathode deposition methods, an initial antimony (Sb) layer is required.

This talk will present the fundamental studies on the initial Sb film properties such as optical properties, thickness, structure and surface morphology. K-Cs-Sb bi-alkali photocathodes based on different Sb layers are deposited and the relation between overall quantum efficiency (QE) and Sb film properties are studied. Optimal Sb film thickness for high QE bi-alkali photocathode is concluded. These studies from the basis for further understanding of the key parameters affecting the cathode performance lead to the development of reliable high performance photocathodes with enhanced quantum efficiency, tunable cathode wavelength and time responses.

8847-5, Session 1

An analysis of the structural and optical properties of Eu doped gadolinium oxide (Gd2O3) planar waveguides fabricated by the sol-gel and dip coating methods

Matthew E. Edwards Sr., Quianna S. Johnson, Ashok K. Batra, Michael J. Curley, Alabama A&M Univ. (United States)

This study focused on the fabrication of Gadolinium Oxide (Gd2O3) and Gadolinium Oxide:Europium (Gd2O3:Eu3+) optical waveguides via the sol-gel and dip coating methods under atmospheric conditions. We have successfully established a method for the preparation and casting of the Gd2O3 sol via the dip coating method. Two different solvents, absolute ethanol and methanol, were used for the preparation of the optical waveguides. Their structural and resulting optical properties, in a waveguide configuration, were studied and compared. A new prism based coupling apparatus was built and used in this study to determine the efficiency of the fabricated waveguides. The optical behaviors and luminescence efficiency of the waveguides were examined according to doping concentration.

8847-6, Session 1

Organic octagonal quasicrystal mircocavity lasers based conjugated-polymer material with ultralow refractive-index

Xiao Chen, Guo-jian Yang, Fei-jun Song, Yi-quan Wang, Minzu Univ. of China (China)

We experimentally demonstrate and characterize an organic octagonal quasicrystal slab with a single-defect microcavity at low-index contrast. The gain medium is the conjugated-polymer, composed by two PPV derivatives, a BEHP-PPV and a MEH-PPV. By optical pumping, the lasing action is achieved at 607 nm with a FWHM of 1nm. The threshold of lasing is 9uJ/cm2. The intensity of the lasing peak depends linearly on the pump energy above the threshold.

8847-7, Session 1

The research on the photoemission of negative electron affinity GaN photocathode

Rongguo Fu, Nanjing Univ. of Science and Technology (China)

Aiming at the photoemission of p-GaN(0001) surface. Activation steps and evaluation of the NEA GaN photoelectriccathode is introduced. Cs and O were used for activation of GaN(0001) surface and the result were tested by using dedicated experimental system for activation and negative electron affinity photocathode. Some data,such as spectral response,quantum efficiency and the photocurrent during activation period etc. were got by the dedicated experimental system. The dipole layer formed on the surface of GaN after the activation with Cs/O is discussed, as the basis for calculating the escape probability of electron. The minority carrier diffusion length and the photoelectron escape depth were fitted by the theory equation,and the theoretical model of the photoemission were established. XPS surface analysis instruments were used for the surface photoelectron spectroscopy analysis before and after the activated GaN photocathode. The research combined with the intrinsic link between the state and the atomic percentage of the surface of Cs?O?Ga and N to determine the structure of the arrangement of surface atoms.Energy band theory were used for built the surface state of the theoretical model of negative electron affinity of GaN (0001) surface. Analysed the intrinsic relationship of negative electron affinity surface morphology ,spectral response , the minority carrier diffusion length, minority carrier lifetime and other parameters. Studied the effect of the mechanism of surface state on photoemission. In order to get high quantum efficiency of the vacuum type ultraviolet detector ,and theoretical basis of NEA photocathode.

8847-8, Session 1

Optical properties of (1-x)Pb(Zn1/3Nb2/3)O3-xPbTiO3 single crystals

Chongjun He, Nanjing Univ. of Aeronautics and Astronautics (China)

Optical properties of (1-x)Pb(Zn1/3Nb2/3)O3-xPbTiO3 (PZN-xPT, x=5%, 9% and 12%) single crystals have been comprehensively investigated. The PZN-xPT single crystals used in this study were grown using a high temperature flux method. Refractive indices (nij) were measured by the Brewster's angles (?B=tan-1n) at different wavelengths. Dispersion equations of refractive indices were obtained. After poled along [001] direction, the transmittance of PZN–12%PT single crystal is more than 65% from 0.5 to 5.8 ?m, which is much higher than that of PZN–5%PT and PZN–8%PT single crystals. PZN–12%PT has a tetragonal phase, its spontaneous polarization PS is along [001] direction. After poling, it could form a single domain structure. Orientation and temperature dependences of the electro-optic coefficient were investigated at He-Ne laser by the Senarmont compensator method. Large effective electro-optic coefficient (?c = 430 pm/V) was observed in [001]-poled PZN-0.09PT crystal. More importantly, ?c of tetragonal PZN-0.12PT is about 130 pm/V, which is almost unchanged in a temperature range -20~80 °C. The ?c of PZN-xPT single crystals are much higher than that of widely used electro-optic crystal LiNbO3 (?c = 20 pm/V). They can be comparable with transparent ferroelectric ceramics PLZT 12/40/60 (140 pm/V). These excellent optical properties make the PZN-xPT single crystals promising candidates for electro-optic modulation applications.

8847-10, Session 2

Enhanced gain dynamics in photorefractive polymers *(Invited Paper)*

Carl M. Liebig, Azimuth Corp. (United States) and Air Force Research Lab. (United States); Steven S. Buller, Air Force Research Lab. (United States); Partha P. Banerjee, Univ. of Dayton (United States); Sergey A. Basun, Azimuth Corp. (United States) and Air Force Research Lab. (United States); Pierre-Alexandre J. Blanche, College of Optical Sciences, The Univ. of Arizona (United States); Jayan Thomas, CREOL, The College of Optics and Photonics, Univ. of Central Florida (United States); Cory W. Christenson, Nasser N. Peyghambarian, College of Optical Sciences, The Univ. of Arizona (United States); Dean R. Evans, Air Force Research Lab. (United States)

Photorefractive polymers have been extensively studied for over two decades and have found applications in holographic displays and optical image processing. The complexity of these materials arises from multiple charge contributions assisting in the formation of competing photorefractive gratings. Analysis of the time dynamics of the two-beam coupling signal is a convenient way to extract the information about the charge species responsible for the grating formation in photorefractive polymers. It has been recently shown that in a photorefractive polymer at relatively moderate applied electric fields, the primary charge carriers (holes) establish an initial grating, followed by a subsequent grating (electrons). This secondary grating competes with the primary grating and decreases the two-beam coupling efficiency. In this paper, it is shown that with relatively large applied electric fields, the steady-state two beam coupling efficiency is enhanced. Our conclusions are supported by experimental two-beam coupling results in a reflection geometry using two different wavelengths (532 nm and 633 nm) and different illumination and biasing conditions.

8847-11, Session 2

Contribution of diffusion and photovoltaic effect to self-pumped reflection gratings in photorefractive lithium niobate

Rola Aylo, Univ. of Dayton (United States) and The Catholic Univ. of America (United States); Partha P. Banerjee, Univ. of Dayton (United States); Sergei A. Basun, Air Force Research Lab. (United States) and Azimuth Corp. (United States); Dean R. Evans, Air Force Research Lab. (United States)

Self-pumped reflection gratings have been extensively studied in various photorefractive materials. In photorefractive lithium niobate, diffusion and photovoltaic effects contribute to grating formation, with the latter being responsible for non-ideal phase difference between the intensity and induced refractive index gratings. The participating optical fields responsible for the intensity and index gratings have to further obey the EM boundary conditions at the interfaces, which are critical in a self-pumped reflection grating geometry.

The transfer matrix method (TMM) is a convenient and rigorous matrix based approach for optical field simulations which takes into account multiple reflections in layered media and all EM boundary conditions. The longitudinal refractive index modulation along the propagation direction is therefore treated as a multilayer system and TMM is applied to analyze two-wave coupling due to self-induced reflection gratings in photorefractive lithium niobate. A simple model for the induced nonlinear refractive index due to diffusion and photovoltaic effects, based on material parameters, is adopted. Since the refractive index is induced, computations are performed iteratively until numerical convergence is achieved. The exact refractive index profile (and optical field distribution) inside the material is computed for the self-pumped reflection grating geometry, along with the overall transmission and reflection, and for both orientations of the c-axis. Numerical simulations are compared with experimental results.

8847-12, Session 2

Lens array plate reference modulation in collinear volume holographic storage system *(Invited Paper)*

Yeh-Wei Yu, Chih-Yuan Cheng, Ching-Cherng Sun, National Central Univ. (Taiwan)

In this era of information proliferation, the demand of huge data storage keeps increasing. Library-style tape storage systems have been used for archive. However, the serial access of this method makes it too inefficient for modern applications. Volume holography storage (VHS) system which owns high access rate, high transfer rate and high storage capacity becomes the best modern solution. Among all the existing VHS techniques, collinear VHS system is treaded as the best candidate for commercial market because of its simplicity and compactness. Unfortunately, the transfer rate is limited by the current technique of reading devices and is slower than the mature tape technique.

The lens array plate (LAP) reference modulation can improve the signal-to-noise ratios (SNR) of collinear VHS 10 times better than current techniques, because the point spread function of colliner system is autocorrelation of reference modulation and the autocorrelation of LAP is very sharp. In this paper, we analyze shift selectivity of LAP and intensity distribution inside the disk of LAP. We also show the transfer rate of collinear system can be improved to compete with the tape technique after optimization of LAP.

8847-13, Session 2

Theoretical model of multilayer collinear volume holographic storage *(Invited Paper)*

Jinqiu Liu, Liangcai Cao, Chengmingyue Li, Qingsheng He, Guofan Jin, Tsinghua Univ. (China)

Collinear holographic data storage (CHDS) is a promising technology for the commercialization of the volume holographic data storage because it is compact and it can provides high data density and high data transfer rate simultaneously[1]. In order to achieve higher data storage density of the CHDS, multilayer recording with a coaxial transmission-type configuration was developed to make full use of the medium dynamic range along the normal direction (z-axis)[2]. Recently, a new multilayer collinear holographic memory with a movable random phase mask (MRPM) has been proposed to reduce the interlayer crosstalk experimentally[3]. The theory of multilayer collinear holographic data storage (MCHDS) is in great need to characterize this method. In this paper, the expression of the stationary holographic fringe in the recording material is presented. The influences of the NA of the object lens and the pattern of the reference beam on the size of the holographic fringe are discussed. Then a theoretical model is applied to calculate the field distribution of the reconstructed light on the surface of the detector by considering the volume recording material as many thin slices. Through calculating the field distribution of the reconstructed image, we sum up the relationship between the size of the holographic fringe in the recording material and the reconstructed pattern. By this method, we could discover why the signal to noise ratio and medium dynamic range consumption are enhanced when the MRPM is applied theoretically.

8847-14, Session 2

History of Kukhtarev's equations and their legacy: band transport model revisited *(Invited Paper)*

Sergei F. Lyuksyutov, The Univ. of Akron (United States)

The author had closely witnessed and monitored progress of Dr. Kukhtarev's ideas and experimental verification of his ideas in the Institute of Physics in Kiev, USSR in the 80s. The renaissance of the photorefractive effect is routinely associated with the paper published in Kukhtarev, Markov, Odoulov, Soskin and Vinetskii "Holographic storage in electrooptic crystals, Ferroelecrics, 22, 949-60 (1979). Although the co-authors of this paper may have different interpretations on the weight of personal contributions, I shall present my, independent, view. There is a consensus of opinion that Kiev group provided the best foundation for the future theoretical and experimental work in the area of photorefraction. There have been plenty of outcomes of Dr. Kukhtarev contributions in the past 40 years: Phase conjugation in photorefractive media, self-oscillation, gain enhancement by detuning, photo-galvanic current, space charge waves, the list will go on and on... This presentation is to tribute Dr. Kukhtarev various contributions in the area of photorefraction.

8847-15, Session 2

Compact crystal accelerator-undulator based on fringing electric-field holographic super lattice *(Invited Paper)*

Nickolai V. Kukhtarev, Tatiana V. Kukhtareva, Alabama A&M Univ. (United States)

We describe modeling of compact crystal electron beam accelerator-undulator, based on the fringing electric field, holographically recorded in the photorefractive crystals. Recently, we have demonstrated that compact pyro electric/photogalvanic crystal accelerator may produce focused electron beam with energies of electrons up to 150

KeV. Focusing structure depends on the crystal geometry and allows producing cylindrical or plain-sheet focused beams. In this paper, we propose combination of compact crystal accelerator with crystal-based electrostatic undulator. In suggested device, the plain sheet electron beam from the compact crystal accelerator is focused into plain wave-guide composed of two crystals. One crystal serves as an additional electrostatic accelerator, another crystal contains build-in electric-field superlattice. The holographically recorded electric field superlattice is serving as a compact electrostatic ondulator, replacing bulky magnetic ondulator used in the traditional free-electron coherent amplifiers and lasers. The theoretical modeling shows that recommended undulator structure might act as an efficient amplifier for a seeding electromagnetic radiation in a microwave and in THz regions. An energy supply for this device may be cheap heat source (in pyroelectric mode of operation) and/or incoherent light source (including sunlight, for photogalvanic mode of operation).

8847-16, Session 2

Laser-induced 2D periodic structures of charged particles concentration in semiconductor under the condition of optical bistability existence

Vyacheslav A. Trofimov, Maria M. Loginova, Vladimir A. Egorenkov, Lomonosov Moscow State Univ. (Russian Federation)

We analyze the laser-induced 2D periodic structure in semiconductor under the condition of the optical bistability existence. Optical bistability appears due to nonlinear dependence of semiconductor absorption coefficient of charged particles concentration because of both the Fermi energy level renormalization and the Burstein-Moss effect. The electron mobility, diffusion of electrons and laser-induced electric field are taken into account at analyzing of laser pulse propagation in the semiconductor.

We found out various modes of laser-induced spatial structure developing on charged particles concentrations in dependence of optical intensity and absorption coefficient. One of them consists in periodic appearance and moving of stable spatial electrons distribution.

8847-17, Session 2

All-normal dispersion photonic crystal fiber for parabolic pulses and supercontinuum generation

Igor A. Sukhoivanov, José Amparo Andrade Lucio, Oleksiy V. Shulika, Univ. de Guanajuato (Mexico); Sergii O. Iakushev, Kharkov National Univ. of Radio Electronics (Ukraine); Alejandro Barrientos García, Univ. de Guanajuato (Mexico); Gabriel Ramos-Ortiz, Ctr. de Investigaciones en Óptica, A.C. (Mexico); Igor V. Guryev, Oscar G. Ibarra Manzano, Arturo Garcia Perez, Univ. de Guanajuato (Mexico)

Supercontinuum (SC) generation is a very active field of research during the last decade. Recently it was shown that all-normal dispersion photonic crystal fibers (ANDi PCFs), which exhibit convex dispersion profiles flattened near the pump wavelength are able to provide highly coherent, flat-top and octave-spanning SC. Here we have designed ANDi PCF with a flat top located at 800 nm. We investigate its applicability for SC generation and parabolic pulse formation with conventional Ti:Sapphire lasers. At the first step we have designed ANDi PCF suitable for SC generation and parabolic pulse formation beyond optical wave breaking. We consider here PCFs with solid core and triangular lattice of air holes. Parabolic pulse formation and supercontinuum generation in this fiber is analyzed both in time and frequency domains by solving GNLSE. It was shown that under pumping within the short wavelength range about 10 nm around the zero-third-order-dispersion wavelength the SC generation is stable under pumping by pulses up to 35 nJ, i.e. does not demonstarate any signatures of breaking neither in time nor frequency domains.

8847-18, Session 3

Side illuminated optical fiber as a multiplexing element for spectroscopic systems *(Invited Paper)*

Claudio O. Egalon, Science & Sensors Technologies (United States) and Los Angeles Harbor College (United States) and Los Angeles Harbor College Physics Club (United States); Michael P. Matta, Robert Y. Insley, Delbert C. Lavezzari, Los Angeles Harbor College (United States)

A new type of colorimeter was demonstrated using a side illuminated optical fiber. This configuration is simple, low cost, does not require a sensitive coating and can analyze multiple samples placed at different positions along the fiber. By side illuminating different spots of the cylindrical surface of the fiber, with multiple light sources, it is possible to guide different signals in a single waveguide resulting in a multiplexed device. In addition to that, this system requires a single detection system that further lowers the cost of analyzing multiple samples.

This proof of concept used a tapered plastic fiber, a support for three LEDs, an inexpensive photo diode, a read-out and food dye solutions of different concentrations. The solutions were placed in different cuvettes along the fiber length and illuminated by the LEDs. Light from the source passes through the solution, strikes the side of the fiber and is guided to the detection system. The measured light intensity and spectral distribution depend on the color and/or darkness of the sample.

Several calibration curves were obtained using different light intensities and detector configurations. It was found that by increasing the light intensity, the sensor sensitivity also increases. It was also found that by making small modifications of the detection system, the colorimeter's dynamic range can also be controlled. By combining these two capabilities we were able to examine distinct dynamic range regions at different sensitivity levels.

With these successful demonstration, this device is now being modified to make fluorescence and scattering measurements.

8847-19, Session 3

Frequency doubled high-power semiconductor disk lasers for stereo projection and ion traps

Alexander Hein, Susanne Menzel, Andreas Ziegler, Rudolf Roesch, Peter Unger, Univ. Ulm (Germany)

We present high-power optically pumped semiconductor disk lasers (OPSDLs) emitting in the 900-1100 nm band which are intra-cavity frequency doubled to access the visible spectrum at blue and green wavelengths. The emission at wavelengths around 450-470 and 520-540 nm yield highly advantageous gamuts for display applications, and can be further utilized for stereo projection. Moreover, certain wavelengths of the converted radiation, e.g. 493.2 nm and the inherent good beam quality of these lasers can be used in optical trapping experiments for ions, inaccessible by other laser types. We focus on presenting the design, fabrication, and characteristics of these devices. In particular, the design of the semiconductor layer structure, the epitaxial growth, device mounting and processing, as well as the thermal management strategy are considered, aiming to produce high optical outputs in the fundamental regime. Preliminary measurements such as photoluminescence and reflectivity spectra are introduced as device assessment tools from which basic characteristics, e.g. the dominant micro-cavity resonance, and expected wavelength and temperature behavior can be derived. During laser operation fundamental output

powers exceeding 20 W, and blue and green radiation with output powers of 5-10 W were achieved with single-chip devices, and operating temperatures of 90°C with watt-level IR outputs were possible. The IR and visible outputs show optical-to-optical conversion efficiencies above 40% and 20%, respectively. Furthermore, broad wavelength tuning ranges of more than 20 nm (513-535 nm) in the second-harmonic regime could be realized.

8847-20, Session 3

Design of the optical concentrator using holographic techniques for solar cells

Wei-Hung Su, Wei-Ting Chen, National Sun Yat-Sen Univ. (Taiwan)

An approach using holographic techniques to fabricate an optical concentrator for a thin film solar cell is described. This concentrator consists of a hologram and a lenticular lens. The lenticular lens collects the sunlights from arbitrary incident angles. The sunlights are then launched into the hologram and generate diffracted light waves. Most of the diffracted waves are normally incident into the solar cell. Thus, reflectivity of the light on the surface of the solar cell is minimized, and the solar energy concentration is increased.

8847-21, Session 3

Broadband large field of view electro-optic modulators using potassium tantalate niobate (KTN) crystals

Yun-Ching Chang, Shizhuo Yin, The Pennsylvania State Univ. (United States); Robert C. Hoffman, Andrew G. Mott, U.S. Army Research Lab. (United States)

It is well known that potassium tantalate niobate [KTa1-xNbxO3 (KTN)] crystals have a large quadratic electro-optic (EO) coefficient. However, high quality, sizable KTN crystals suitable for device fabrication have only become commercially available in the past several years. By taking advantage of the recent advances in KTN crystal growth, a broadband large field of view (FOV) EO modulator is developed and presented in this paper. The experimental and theoretical studies indicate that the built EO modulator not only has a broad bandwidth (~ 1 GHz) but also has a large FOV (+/- 30 deg) because cubic phase KTN crystals do not introduce any intrinsic birefringence without applying the external electric field. Furthermore, unlike waveguide-based EO modulators that have a very small (a few microns) cross section with a multi-gigahertz bandwidth, the EO modulator presented in this paper has a larger (from millimeter to centimeter range) cross-section. The result is a core enabling device for several practical applications such as modulating retro reflector (MRR) for broadband free space optical communications. Finally, the modulation bandwidth can be further enhanced by taking advantage the broad transmission band (400 nm - 4000 nm) of KTN crystals (e.g., using WDM).

8847-22, Session 3

Novel design of a highly sensitive micro-displacement sensor based on photonic crystal waveguides

Ravindra K. Sinha, Himanshu Chauhan, Preeti Rani, Yogita Kalra, Delhi Technological Univ. (India)

A novel ultra-sensitive design of micro-displacement sensor, useful for integration with MEMS, consisting of fixed and movable PCWGs is presented. The sensor design consists of the PC of hexagonal array and creation of angular intersection of a PCWG (of width 5.52 µm) with the common axis of the fixed (connected to a stationary substrate) and movable PCWGs. The 2-D hexagonal arrangement (a=2.76µm) of air holes (r=1.1µm) drilled in Silicon, is taken into consideration because of its practical reliability and fabrication. The band diagram of the structure is numerically simulated using Plane Wave Expansion (PWE) method and it is found that the TM mode of wavelength 9.02µm appears in the midst of the Band-Gap region. The operation of the device with the working wavelength of 9.02µm emitted from a Co2 laser with a view of its industrial applications.

Numerical simulations with the magnitude of angular displacement of moving PCWG increasing by 0.2µm at each step of simulation have been performed. Sensing is performed by analyzing the energy distribution among the PCWGs and by detecting the variation of Difference in normalized-Power (DIP) exiting the waveguides.

The sensitivity of the proposed novel design is much better than the existing literature's results. The sensitivity of the proposed design is also compared with photonic crystal structure in square lattice in silicon and also with silicon rods assembled with hexagonal lattice with a view of its applications in photonic crystal based MEMS.

Full-wave FDTD analysis of nonlinear photonic crystal fibers

Igor V. Guryev, Igor A. Sukhoivanov, José Amparo Andrade Lucio, Everardo Vargas Rodriguez, David Claudio Gonzalez, Ruth Ivonne Mata Chavez, Oleksiy V. Shulika, Univ. de Guanajuato (Mexico)

Nowadays, technology allows creating photonic crystal fibers with almost any imaginable refractive index profile which leads to a variety of applications. Therefore, at the design stage it is important to be able to predict and optimize their characteristic. Existing FDTD-based methods allow treating for the material dispersion. However, in case of femtosecond pulses propagation or high-power CW lasers the waveguide dispersion is changed due to optical nonlinearity. Another important drawback of the existing methods is using the square unit cell of the fiber. This assumption allows quite easy implementation of the Leap-Frog algorithm and is acceptable for eigen-frequency computation and modes analysis. However, it introduces an error into the waveguide dispersion value.

In this work we have developed, implemented and optimized the full-vectorial FDTD-ADE method for precise investigation of dispersion characteristics of nonlinear photonic crystal fibers. The method takes into account hexagonal shape of the fiber unit cell, material dispersion of the refractive index and the nonlinear effects. In case of low intensity (linear case), the dispersion have been compared with the one obtained by the full-vectorial finite elements method which is proved to be precise and stable. In case of high radiation intensity (nonlinear case) the FDTD-ADE method has shown good results in the works published by Allen Taflove.

The method is implemented using advanced computing technologies such as parallel computing and GPU computing and is tested on the supercomputer "Piritakua" of the University of Guanajuato. High performance of the method allows using it in the optimization algorithms.

8847-24, Session 3

Phase-shift formed in a tapered long period fiber grating and its application to simultaneous measurements of temperature and refractive-index *(Invited Paper)*

Hongpu Li, Keisuke Hishiki, Shizuoka Univ. (Japan)

In the past few decades, the studies on the phase-shifted long-period fiber grating (LPG) have attracted increasingly interest attributed to its unique properties, such as the narrow resonant bandwidth, high sensitivity to the environmental parameters which makes it the ideal role being utilized as the all-fiber-type biochemical sensor, optical switching, and all-optical processing elements. To date, various methods have been developed to fabricate the phase-shift LPGs. However, until present, the quantitative analyses on the calibration of the resulted phase-shift and the relationship between the transmission characteristics (wavelength of the loss peak and the loss depth) and the amount of the phase-shift have rarely been investigated, which is, however, very important and strongly demanded for its practical application to either the all-optical signal processing or as a high-sensitive fiber devices for measuring the environmental parameters, such as the temperature, strain, transverse load, pressure, and refractive index-change of the surrounding materials. In this paper, a novel approach to calibrate a phase-shift formed in a LPG is proposed and successfully demonstrated, which is based on the use of either a power- or a wavelength-interrogation technique to the loss-peak existed in the transmission spectrum of the phase-shifted LPG. Moreover, in this study, by tapering a LPG with CO2 laser, phase-shift is successfully created at central part of the LPG. Finally, base on the use of this kind of phase-shifted LPG, a simultaneous measurement for the temperature and the surrounding refractive index has been proposed and experimentally demonstrated.

8847-25, Session 3

Intra-cavity index sensor based on ytterbium-doped photonic crystal fiber

Ying Lu, Tianjin Univ. (China)

Photonic crystal fiber with air holes in the cladding region has attracted high attention in the development of new all-fiber sensor due to its many peculiar properties, just like the endless single-mode characteristic, controllable dispersion, etc. In this paper, we propose an intra-cavity index sensor based on double cladding ytterbium-doped photonic crystal fiber filled with liquid analyte in the air holes of optical fiber cladding. The proposed Yb3+-doped photonic crystal fiber consists of two claddings and an Yb3+-doped core and the internal claddings consists of three layer air holes. In such sensor, when pumped by 976 nm light, the output power of the ytterbium-doped photonic crystal fiber laser at 1060nm can be influenced obviously by a bit change of the refraction index of liquid analyte in the air holes of optical fiber cladding to achieve the intra-cavity fiber sensing. We have got the relationship between effective refractive index of analyte and the confinement loss, output power of intra-cavity index sensor and cavity loss coefficient, output power and the end reflectivity by finite element method, respectively. The numerical analysis shows that the power change is larger in a small range of loss when the end reflectivity is higher, and the sensor's sensitivity will be higher for the change of refractive index of analyte. The intra-cavity photonic crystal fiber sensing system has great practical value and significance for their advantages of compact structure and high sensitivity.

8847-26, Session 3

Piezoelectric resonance calorimetry of nonlinear-optical crystals under laser irradiation

Aleksey V. Konyashkin, Oleg A. Ryabushkin, Daniil V. Myasnikov, Institute of Radio Engineering and Electronics (Russian Federation) and Moscow Institute of Physics and Technology (Russian Federation); Valentin A. Tyrtyshnyy, Oleg I. Vershinin, Institute of Radio Engineering and Electronics (Russian Federation)

Conventional method for the precise determination of optical absorption coefficients of nonlinear-optical crystals is laser calorimetry. It is based on measurements of the heating kinetics of air near the crystal surface during and after laser irradiation. Both optical absorption and heat transfer coefficients are then calculated by solving nonstationary heat conduction equation taking into account boundary conditions. Novel modification of calorimetry technique that we propose is to use concept of the crystal equivalent temperature (?eq) for measuring temperature kinetics of laser heated nonlinear-optical crystal. Piezoelectric resonances are observed in radiofrequency spectra of the crystal response to the applied probe electric field. Preliminary calibration of resonance frequency Rf dependence on temperature is performed during uniform crystal heating. So each Rf value corresponds to the certain crystal temperature T and Rf linearly depends on temperature with piezoelectric resonance thermal coefficient Kprt. Then crystal's ?eq kinetics is directly measured using resonance frequency shift ?Rf dependence on time when the laser power is switched on. Characteristic time constant ? of crystal ?eq kinetics during laser heating is determined using exponential fitting: Rf(t)=[Rf(0)–Rf(P)]exp(–t/?)+Rf(P), where Rf(P) is stationary value corresponding to laser power P. Equivalent temperature stationary value is ?eq(P)=T0+?Rf(P)/Kprt, where T0 is crystal temperature at P=0. This approach allows to measure precisely nonlinear-optical crystal true temperature kinetics during its laser heating and to determine both heat transfer and optical absorption coefficients using nonstationary heat conduction equation. Both coefficients were measured for LBO and PPLN crystals using CW Yb-doped fiber laser (1064 nm).

8847-27, Session 3

The path forward: silicon optical modulator for CMOS ICs

Kaikai Xu, Guann-pyng Li, Univ. of California, Irvine (United States)

It is widely known that a reverse-biased p-n junction under avalanche breakdown has the ability to emit visible light. This paper reviews a silicon p-type metal-oxide-field-effect-transistor (Si-PMOSFET) device that can work as two gate-controlled diodes symmetrically connected in parallel. More specifically, the "P+ type Drain/Source" terminal is connected to the ground and the "N type substrate" terminal operates at a positive voltage that is a fixed value, thus the variation of the voltage of the insulated-gate terminal can adjust the field distribution at the depletion region of the "P+ type Drain/Source"-"N type substrate" reverse-biased junction. Due to the correlation of the breakdown current flowing through the p-n junction and the optical emission power from the avalanching region of the p-n junction as a function of the filed distribution, the optical intensity seems to be reasonably feasible by means of the varying the gate voltage. It is noted that, compared with the Si-diode LED, a major advantage of the Si-PMOSFET LED is that this device is a three-terminal device which has a gate terminal. Moreover, because of the full compatibility with the standard silicon complementary-metal-oxide-semiconductor (CMOS) process, this Si-PMOSFET LED is capable of integrating with other silicon devices or circuits very well to realize monolithically optoelectronic integration.

8847-28, Session 4

Active gating as a method to inhibit the crosstalk of single photon avalanche diodes in a shared well *(Invited Paper)*

Anna Vilà, Eva Vilella, Oscar Alonso, Andreu Montiel, Angel Dieguez, Univ. de Barcelona (Spain)

Recent advances in Single Photon Avalanche Diode (SPAD) arrays have been proposed to improve the fill factor, by confining several SPADs in the same macropixel sharing the well. The main issue of this approximation relates to the ease of crosstalk, as the charge generated by the avalanche in a pixel can easily arrive through the substrate until the neighbouring ones. This crosstalk grows with the signal, and consequently can represent a non-negligible noise in the receiving pixel. In significant applications of SPAD arrays in which the measurement is triggered only in short and well-defined time periods that are known in advance, such as 2D and 3D vision systems of fluorescence lifetime imaging microscopy, the pixels can be inhibited before the arrival of the crosstalk charge.

To evaluate the effectiveness of this approximation, this paper reports the crosstalk characterization in an array of five SPADs fabricated in conventional 0.35um HV-CMOS technology in the same n-well, giving a fill factor of 67%. Measuring with a long gating time a crosstalk not less than 5% is observed. However, reducing the gating time below 4ns completely eliminates the crosstalk, as predicted by the theory and by TCAD simulations. The technique has shown to provide good spatial resolution and contrast in 2D imaging with the proposed SPAD technology.

8847-29, Session 4

Fabrication of nanostructures on curved surfaces

Shizhuo Yin, The Pennsylvania State Univ. (United States); Paul B. Ruffin, Christina L. Brantley, Eugene Edwards, U.S. Army Research, Development and Engineering Command (United States); Claire Luo, General Opto Solutions, LLC (United States)

In this paper, the fabrication of nanostructures in curved surfaces is presented, including the used materials, the fabrication methods, and the experimental results. The potential civilian applications such as broadband anti-reflection coating for optical lenses are also discussed.

8847-30, Session 4

Torsion sensor using a Mach-Zehnder interferometer

Daniel Toral-Acosta, Univ. Autónoma de Nuevo León (Mexico); Juan M. Sierra-Hernandez, Daniel Jauregui-Vázquez, Univ. de Guanajuato (Mexico); Arturo Castillo-Guzmán, Univ. Autónoma de Nuevo León (Mexico); Roberto Rojas-Laguna, Julián Móises M. Estudillo-Ayala, Univ. de Guanajuato (Mexico); Romeo Selvas-Aguilar, Univ. Autónoma de Nuevo León (Mexico)

In this paper, a novel torsion sensor base on a Mach-Zehnder interferometer is presented. The interferometer is achieved by fusion splice an Ytterbium doped photonic crystal fiber (YbDPCF) of double cladding between two single mode fibers (SMF). When a single mode fiber and an YbDPCF are fusion splice, a collapse of air holes take place, thereby the fundamental mode of the SMF enters into YbDPCF to cause core and cladding modes excitation. Hence a modal interference technique is achieved using this interferometer. This technique is induced because the cladding of the YbDPCF has an effective refractive index smaller than the core index therefore a phase difference between cladding and core is produced. This phase difference generates two optical paths and consequently some modes are propagating both the core and cladding. Then, the YbDPCF is fusion splice with another single mode fiber obtaining a SMF-YbDPCF-SMF structure. An image of the modes propagation inside of the YbDPCF was achieved. This image was obtained using an optical beam profile. The torsion sensitivity obtained is 0.05nm/° in torsion range from 0° to 360° along with a sensitivity of 0.06 dBm at a specific wavelength. Finally the interference fringes and torsion characteristics have been experimental investigated and demonstrated. This compact fiber component with acceptable sensing performance makes it a good candidate for the measurement of numerous physical parameters.

8847-31, Session 4

Band-stop filter at microwave frequencies using metallic photonic bandgap structures

Manoj K. Tiwari, Univ. of Delhi (India); H. C. Gupta, D. C. Dube, Indian Institute of Technology Delhi (India)

In this paper design and fabrication of a wide band One-Dimensional Photonic Bandgap Structures (PBS) which leads to Band Stop Filter (BSF) at 12 GHz is presented. Design and fabrication of One-Dimensional PBG-BSF is carried out and the effect of variation in period of the lattice and defect on propagation characteristics of 1-D PBG-BSF is studied. Firstly the eight slot periodic structures in one dimension are created on very thin metallic sheet and then by breaking the periodicity of the structure, a defect state is created in the PBG structures. The defects thus created leads to isolated energy levels within the energy gap. Defects may permit localized modes to exist with frequencies inside the PBG. Some of the measured results have been verified with the modeling results using MoM based IE3D software. In particular for the frequency range 6 GHz to 13.5 GHz, with a wide band gap centered at 12 GHz has been observed with the performed experiments for eight slot one dimensional PBG structure and this has band width of 1 GHz (approximately) agreeing well with the simulated results. Various other one Dimensional PBG periodic structures and structures with defect is fabricated and transmission parameter is observed which agrees well with the simulated results. Detail fabrication parameters and methods will be presented at length in the full paper.

8847-32, Session 4

Dynamic characteristics and optimization of optical power limiter based on Kerr saturable nonlinear photonic crystal

Juan R. Cabrera Esteves, Igor V. Guryev, José Amparo Andrade Lucio, Igor A. Sukhoivanov, Everardo Vargas Rodriguez, Univ. de Guanajuato (Mexico)

New advances on recent Pulsed and CW high power lasers are being widely used on optical communication. The compact and effective optical limiters have more important than ever. The aim of this work is to investigate the dynamic characteristics of a structure of photonic crystal with a nonlinear element as well as to optimize the parameters of the structure to create an optical limiter suited both for CW and pulsed radiation. The finite-differences time-domain (FDTD) method extended by the auxiliary differential equation (ADE) was applied to obtain the intensity-dependent spectra data of the structure for both CW and pulsed radiation. With data obtained, we generated graphics for both transmission spectrum and transmission characteristics at different intensities. According with graphics, the optical limiting was observed within wide wavelengths range for both CW and pulsed radiation. Therefore, due to scalability properties of PhC, the required limiting can be achieved by proper geometry selection. In spite of the lots of advantages such as compactness, integrability and tuneability, the investigated structure has significant disadvantages to be worked on. The most important one is the dependence of the characteristics on the pulse duration. This happens because of the high-Q resonator formed by the PhC with defect. However, with further optimization this disadvantage can be entirely eliminated.

8847-33, Session 4

Design of photonic crystal architecture for optical logic and gates

Ravindra K. Sinha, Preeti Rani, Yogita Kalra, Delhi Technological Univ. (India)

In this paper, we report the designs of optical logic AND gates in Y shaped photonic crystal waveguides based on two structures, one of which is a hexagonal lattice with silicon rods in air (SRA) and another is the hexagonal lattice arrangement of air holes in silicon (AHS). In both the structures an air waveguide with two input ports and one output port has been created and a rod in one design and a hole in another design have been introduced at the center of the Y shaped waveguide. After the optimization, the radius (rc) and interaction length (L) of the central rod for rod structure has been taken as rc =0.05a and L=0.1a, respectively,

where 'a' is the lattice constant. For AHS structure, the radius of central hole in the Y shaped air waveguide has been optimized as rc =0.25a. After the optimization, the proposed structures have been verified to work as AND gates using the FDTD method. For input launch at the single input port, output power for SRA and AHS structures have been obtained as 0.328P0 and 0.406P0, where P0 is the input power. Similarly for input launch at both the input ports, output power obtained for SRA and AHS structures are 1.310P0 and 1.624P0. It has been analyzed that the bit rate for SRA structure is 2.016Tbit/s and for the AHS structure is 1.785Tbit/s. Thus, the proposed photonic crystal structures could really work as an efficient AND optical logic gates.

8847-34, Session 4

Tiering effect of solid-core photonic crystal fiber on controlled coupling into multimode fiber

Angela Amphawan, Univ. Utara Malaysia (Malaysia) and Massachusetts Institute of Technology (United States); Nashwan M. A. Al Samman, Univ. Utara Malaysia (Malaysia)

Premise backbones, primarily multimode fiber (MMF), are reaching their fundamental capacity limits due to rapidly increasing bandwidth demands driven by the advent of multimedia-rich data services. Current techniques for advancing the capacity limit of MMF include controlled coupling, electronic dispersion compensation (EDC), offset launch, wavelength division multiplexing and orthogonal frequency division multiplexing. Controlled coupling into a MMF by contriving the launch beam to substantially fit an eigenfunction of the MMF waveguide have been achieved using spatial light modulators (SLMs), single mode fibers (SMF), phase masks and gratings. Controlled coupling improves the channel impulse response of the MMF by suppressing undesirable modes, converting modes or equalizing the arrival times of propagating modes. Solid-core photonic crystal fibers (SC-PCFs) offer an attractive alternative for increasing the transmission capacity of MMF via controlled coupling. This paper explores the potential of SC-PCF for controlled coupling into a MMF. Several structural designs of solid-core PCF waveguides are explored. The power coupling performance is evaluated in terms of the power coupling efficiency from the SC-PCF into the MMF, distortion of the spatial transverse modal field at the MMF and bit-error rate. It is shown that the power coupling from the PCF to the MMF may be controlled by the diameter of the air holes, the distance between two holes and the ratio of the distance between the holes and the size of the hole. The power coupling performance is investigated at three wavelengths - 850nm, 1300nm and 1550nm.

8847-35, Session 4

Optimization of maximum power transfer in outer waveguides by properly designing the inner waveguide and using modified coupled mode analysis for graded index multi-waveguide systems

Krishna Ch. Patra, Sambalpur Univ. (India); Sangeeta Srivastava, Univ. of Delhi (India); Enakshi K. Sharma, Univ. of Delhi South Campus (India)

We present the modified scalar coupled mode analysis for the N-waveguide diffused channel waveguide directional power coupler. The study simulates the lateral evanescent field coupling in Graded Index Multi-Waveguide Systems. In a two-step procedure, the propagation characteristics of individual waveguides have been obtained first using the completely analytical variational approach. Consequent upon obtaining the individual waveguide characteristics, the complete scalar coupled mode theory has been developed to obtain the supermodes corresponding to the coupled waveguide configuration. The fabrication technique of the inner waveguide for maximum power transfer between the outer waveguides is optimized properly.

8847-36, Session 4

Ultrafast transient characteristics of photoconductive elements for optical wireless communications

Xian Jin, Christopher M. Collier, Jamie Garbowski, Brandon Born, Jonathan F. Holzman, UBC Okanagan (Canada)

Semiconductor switches are important photoconductive (PC) devices for modern optoelectronic communication systems. Advancements in these PC devices have focused mainly on optical fibre implementations—with material and structural developments establishing ultrafast optoelectronic switching times. The use of PC devices becomes complex, however, when these elements are applied to emerging optical wireless communications (OWC) systems as visible light links. Indoor visible light OWC systems are typically deployed with distributed optical lighting/transmitter grids, so mobile PC devices must offer multidirectional and broadband capabilities (along with the aforementioned capability for ultrafast optoelectronic switching times). Integration of all these OWC capabilities can be challenging.

In this work, an integrated PC sensor is studied for use in visible light OWC links. The sensor applies the standard PC switch, being a biased metal-semiconductor-metal gap, in a three-fold-symmetric corner-cube architecture with a summed output photocurrent at the vertex. Such a form facilitates bidirectional retroreflective communications while meeting the OWC requirements for multidirectional and broadband capabilities. The ultimate capability for ultrafast optoelectronic switching times must be carefully considered, however. The 3-D form that allows for multidirectionality also introduces an internal transit time response, while the visible light photoexcitation that allows for broadband operation also introduces a complex transient material response. These transit time and material responses are analyzed in this work for the integrated PC sensor. It is shown that the responses can be carefully balanced for ultrafast (picosecond) optoelectronic switching times. Such a device can become an important element for emerging visible light OWC systems.

8847-37, Session 4

Equivalent temperature of nonuniformly heated nonlinear-optical crystals in course of laser radiation frequency conversion

Aleksey V. Konyashkin, Oleg A. Ryabushkin, Daniil V. Myasnikov, Institute of Radio Engineering and Electronics (Russian Federation) and Moscow Institute of Physics and Technology (Russian Federation); Valentin A. Tyrtyshnyy, Institute of Radio Engineering and Electronics (Russian Federation); Andrey I. Baranov, Institute of Radio Engineering and Electronics (Russian Federation) and Moscow Institute of Physics and Technology (Russian Federation)

Precise temperature control of the nonlinear-optical crystals plays crucial role in various laser frequency conversion processes. Piezoelectirc resonance spectroscopy technique gives opportunity to measure the crystal temperature during its linear and nonlinear interaction with laser radiation. This method is based on the registration of the crystal piezoelectric resonance frequency Rf change caused by the interaction of the laser radiation with crystal. Piezoelectric resonance can be observed by measuring the response of crystal sample to the applied external electric field. Electric field of the varying radiofrequency affects the nonlinear-optical crystal (PPLN), which is placed in unclamped manner between two strip electrodes and is connected in series with the load resistor. For each value of the electric field frequency the amplitude and the phase of the voltage on the resistor are measured by the lock-in amplifier. Preliminary calibration of resonance frequency dependence on temperature T is performed during uniform crystal heating. Here Rf linearly depends on temperature with coefficient Kprt. It is shown that nonuniform crystal heating by laser radiation can be characterized by equivalent temperature ?eq. At certain pump power P the crystal equivalent temperature is directly determined from measured Rf shift: ?eq(P)=T0+?Rf(P)/Kprt, where T0 is crystal temperature at P=0. In present work temperature tuning curves of PPLN crystal and its phase matching temperature dependence on pump power (CW ytterbium fiber laser up to 25 W) were precisely measured in second harmonic generation experiment. Hysteresis of PPLN temperature and optical bistability of the second harmonic power in respect to pump power were observed.

8847-9, Session PMon

Band gap control of photonic crystal cell fabricated using block copolymer and hydrogel with electric field

Youngbin Baek, Dongmyung Shin, Bona Yang, Hongik Univ. (Korea, Republic of)

Optical and electrical characteristics of the devices using photonic gel film and hydrogel were studied. Poly(styrene-b-2-vinyl pyridine) (PS-b-P2VP, 52k g/mol – b - 57k g/mol) lamellar structure with alternating hydrophobic-block and hydrophilic-block polymers were prepared for the photonic crystal film. Poly(acrylamide-co-acrylic acid) sodium salts were prepared for the hydrogel. This hydrogel is water swelling material and it-owned ions for a device has conductivity. Photonic gel film was coated onto Indium tin oxide (ITO) glass for make electric fields by spin coater. The reflectance maximum wavelength of photonic crystal device shifted from 538 nm and reached to 557 nm, 585 nm and 604 nm during 30 min voltage applying time. The bandwidth variation was very limited. Loss of electrolyte was much less with hydrogel compared to the pure water. We can control color of photonic device by electric field with reasonable time range under moderate electric field by applying 2 V between two facing electrode.

8847-38, Session PMon

Mach-Zehnder interferometer in a rod-type photonic crystal

Maojin Yun, Meiling Liu, Feng xia, Wei Lv, Zan Zhang, Qingdao Univ. (China)

Photonic crystals have attracted great attention and quickly became the subject of extensive worldwide research due to their unique ability to manipulate light. The distinguished properties of photonic crystal, such as superlensing effect, negative refraction, and self-collimation effect have been widely studied. Self-collimation effect allows light propagation without diffraction in perfect photonic crystal. We propose a compact?high efficient photonic crystal Mach-Zehnder (MZ) interferometer based on the self-collimation and photonic band gap in a Rod-type Photonic Crystal . Line defected photonic crystals are used as the beam splitter and the mirror. Self-collimation frequency range is confirmed by using the plane wave expansion method. The interference is investigated with the finite difference time domain(FDTD) simulation technique, and the simulation results agree well with the theoretical prediction. Because of their small dimensions, the proposed MZ interferometer holds great potentials for applications in photonic integrated circuits.

8847-39, Session PMon

Focusing on the graded negative index lens by annular photonic crystal

Maojin Yun, Feng Xia, Hongying Yi, Meiling Liu, Wei Lv, Zan Zhang, Qingdao Univ. (China)

Focusing on the graded negative index lens made by annular photonic crystal (APC) is theoretically studied. The graded annular photonic crystal (GAPC) is composed of a dielectric-rod and a circular-air-hole array in a triangular lattice. The grade index is achieved by gradual modification of the radius of the rod along the transverse direction to propagation. The properties of the GAPC are analyzed by using the Plane Wave Expansion (PWE) method and the numerical simulation is studied by using the Finite-Difference Time-Domain (FDTD) method. Numerical simulation results show that the GAPC can realize the focus of plan waves and the focal length can be designed with the formula of modification and the wave frequency. The designed GAPC has the potential application for coupling with various types of waveguides.

8847-40, Session PMon

Optimization of high fixed diffraction efficiency in LiNbO3:Ce:Cu using optimal switching from recording to fixing

Peipei Hou, Ya'nan Zhi, Jianfeng Sun, Yu Zhou, Lijuan Wang, Wei Lu, Liren Liu, Shanghai Institute of Optics and Fine Mechanics (China)

Optimization of high fixed diffraction efficiency in LiNbO3:Ce:Cu is investigated. The nonvolatile holographic recording is realized in LiNbO3:Ce:Cu for different doped concentration. Holographic gratings are recorded using typical recording wavelengths including 488, 514, 633 and 799nm. There is an optimal switching time for the maximum diffraction efficiency up to an ideal of 100%. The fixed holograms are developed by an original recording setup. Diffraction efficiencies of recording and fixing are measured by a two-wave coupling technique. The experimental results are analyzed and compared. The optimal recording wavelength and doped concentration for high fixed diffraction efficiency is discussed in detail.Through the analyzed, the optimal recording wavelength and doped concentration for high fixing efficiency in LiNbO3:Ce:Cu is provided. This work can obtain high persistent diffraction of the nonvolatile holographic storage in LiNbO3:Ce:Cu crystals.

8847-41, Session PMon

High speed and low side lobe optical phased array steering by phase correction technique

Aimin Yan, Zhijuan Hu, Wangzhou Shi, Yadong Jin, Shanghai Normal Univ. (China)

Laser beam scanners are important optical elements with a large variety of applications in the measurement techniques, optical communications, laser imaging ladar, etc. Agile beam steering of optical radiation using phased arrays offers significant advantages, such as weight, stability and power requirements over conventional beam steering systems. There are several kinds of optical phased array technology to be developed, such as Lithium tantalite phase shifters, lithium niobate electro-optic prism deflectors, and liquid crystal and ferroelectric liquid crystal phase modulations. However, one of the major drawbacks of these approaches is low light efficiencies because of the side lobes in far-field pattern of the steering beam.

In this paper, a new low side lobe optical beam steering technique using phase correction technique is proposed. A stable and fast single-lobed far-field pattern in steering beam can be obtained from the optical

phased array with a phase plate by optima design. It can result in a substantially increased light efficiency and beam quality. The quantitative calculation results of typical optical phased array are demonstrated. The low side lobe optical beam steering technology of optical phased array will benefit many practical applications such as laser ladar, laser communications and high resolution displays.

Group delay properties of linear chirped Gaussian pulse diffracted by volume gratings

Huili Chen, Aimin Yan, Zhijuan Hu, Wangzhou Shi, Yadong Jin, Congling Lv, Shanghai Normal Univ. (China)

Volume gratings are of wide interest in many applications because of their properties of high diffraction efficiency, excellent wavelength selectivity and angular selectivity. Ultrashort pulsed laser has many promising applications in the fields such as optical communication, signal and imaging processing. Because of its abundant spectrum and wide bandwidth, the diffraction properties of volume gratings under illumination by ultrashort optical pulse will be different from that of a monochromatic continuous wave. A periodical structure is highly dispersive and such a dispersive property can be used to control the group velocity of light beams. So the spectral properties and dispersive properties of the periodically layered structures such as volume gratings when a linear chirped Gaussian pulse illuminated are very necessary. These properties can be applicable to addressable filter, switching, and controllable optical delay line. In this paper, a detailed study of linear chirped ultrashort pulsed beams diffracted by volume gratings in dispersive media is performed. The group delay characteristics of the diffraction spectrum of the transmitted and reflected volume gratings were studied based on a modified coupled wave theory. The analysis and observation of this paper will be valuable for the designing optical elements based on diffractive structure for use with linear chirped ultra-short pulsed waves.

8847-43, Session PMon

Performance analysis of electrochromic coloration efficiency by the oxygen deficiency in the sputtering a-WOx films

Jyh-Jier J. Ho, National Taiwan Ocean Univ. (Taiwan)

In this paper, we report on how electrochromic coloration is affected by oxygen deficient stoichiometries in amorphous tungsten oxide (a-WOx) films prepared by a dc reactive magnetron sputtering. The peak color efficient (CE) value of oxygen partial pressure at the optimum 6.5Exp(-3) Torr is improved about nine-fold larger than that of 2.0Exp(-3) Torr even in the nearly stoichiometric a-WOx films. We attributed that the optical absorption of a colored a-WOx film can be satisfactorily described by an intervalence charge-transfer transition (ICTT) mechanism between localized W5+ and W6+ states. Therefore, we have determined the most suitable condition (by increasing the partial oxygen pressure) to produce a-WOx films, thus offering a good electrochromic performance for opto-switching applications.

8847-44, Session PMon

Cochleate plastic photonic fiber

Soeun Kim, Young Soo Lee, Gwangju Institute of Science and Technology (Korea, Republic of); Chul-Sik Kee, Gwangju Institute of Science and Technology (Korea, Republic of) and Gwangju Institute of Science and Technology (Korea, Republic of); Chung Ghiu Lee, Chosun Univ. (Korea, Republic of)

In recent years, terahertz (THz) radiation has attaracted considerable interest using plastic photonic crystal fiber (PCF). PCFs consisting of waveguiding core and a cladding layer with spatially periodic air holes are currently another subject of intensive research. Compared with the conventional optical fibers, the PCF exhibits unusual optical properties, such as single-mode operation, anomalous dispersion, and large mode area.

We propose cocheleate plastic photonic fiber as a new design for THz optical fiber, Using finite difference time doamin computational strategy, the modal characteristics of the proposed fiber is analyzed. The proposed Teflon fiber is fabricated by using Teflon rod, tube and sheets. Teflon rod and tubes are arranged in a row on the adhesive Teflon sheet and rolled up tightly. As a result, cocheleate plastic photonic fiber is developed. By using a THz time domain spectroscopy technique, the propagation characteristics of sub-ps THz pulses are investigated

Shifting selectivity of shift-multiplexing volume holographic storage system enhanced by unbalanced spherical wave

Yeh-Wei Yu, Chih-Yuan Cheng, Chi Shou Wu, Che-Chu Lin, Xuan Hao Lee, Ching-Cherng Sun, National Central Univ. (Taiwan)

Shifting multiplexing holographic storage system is compatible to traditional optical storage system since it only needs rotating the disk to apply multiplexing. Therefore, it is more possible to be commercialized. However, Bragg degeneracy causes series inter-page crosstalk. In this paper we propose spherical wave front with Astigmatism aberration to enhance the shift selectivity in the direction of Bragg degeneracy. The reference wave has an unbalanced wave front, which is divergent tangential direction (x direction) and convergent radial direction (y direction). The reference can be expressed as a line shape light source with divergent phase distribution in x direction and convergent phase distribution in y direction. We introduce Astigmatism in the reference beam to improve the shift selectivity in the direction of Bragg degeneracy. Experimental results are used to demonstrate the idea. For LiNbO3 locates 4mm away from the focusing line, we get balanced shift selectivity in both x and y direction. When central region in y direction of reference wave is blocked, the shift selectivity along y direction is enhanced to be 10?m.

Effect of light intensity on quasi-nonvolatile holography in doubly doped LiNbO3:Fe:Ru crystal

Zhifang Chai, Daoyang Bao, Yu Chen, East China Normal Univ. (China); Ya'nan Zhi, Shanghai Institute of Optics and Fine Mechanics (China)

The doped LiNbO3 has been extensively studied as one of the most promising materials for volume holographic data storage systems. However, holographic grating recorded in LiNbO3 is usually volatile during readout. To overcome it, several techniques such as thermal fixing, electric fixing, and two center recording have been proposed so far.

Quasi-nonvolatile readout with extended lifetime is found in some doubly-doped LiNbO3 crystal including LiNbO3:Tb:Fe and LiNbO3:In:Fe crystals. Experimental investigations show that high asymmetry in grating buildup and readout erasure rates can be observed when one color holographic recording is performed in these crystals.

Quasi-nonvolatile readout can be observed in the oxidized LiNbO3:Fe:Ru crystal when one color holographic recording is performed. In this paper, we focus on the effect of the total recording and readout light intensity on quasi-nonvolatile holography is investigated experimentally. Different intensities are used in the recording process and readout process in the experiments. The results show that the grating lifetime can be greatly extended by decreasing recording and readout light. At last, the reason for the high asymmetry is explained qualitatively in terms of a multiple center model

Density of modes maps for design of nonlinear photonic crystal devices

Igor V. Guryev, Igor A. Sukhoivanov, José Amparo Andrade Lucio, Oscar G. Ibarra Manzano, Univ. de Guanajuato (Mexico)

In this work we present numerical results on characterization of the transmitting properties of the PhC linear and nonlinear filters confined within the waveguide. Novel characteristics of the PhC filters such as density of modes (DOM) maps and transmission maps are computed, and their efficiency analyzed. Presented characteristics can be used as an auxiliary optimization tools to reduce optical losses when designing high-efficient integrated optical components.

The DOM maps have been computed by means of the plane wave expansion method (linear and non-dispersive case) and by the FDTD method (to take into account nonlinearity and the refractive index dispersion)

DOM maps obtained by the PWE method have been compared with the ones found by the FDTD which have demonstrated their full correspondence to the transmission spectra of the filter. The PWE results possess higher contrast and allows investigate in details the eigen-states properties and behavior. On the other hand, DOM computed by means of the FDTD method give better representation of an actual transmission spectra and can be applied for design of the nano-optical devices.

Computed DOM map of the nonlinear PhC (rods-in-air) demonstrated significant variation of the DOM at large radii of the filter holes due to a larger fill-factor of the nonlinear material.

Proposed DOM maps allow precise characterization and optimization of the PhC filter properties with much lower computation time as compared to the field computation inside the device.

Defect soliton in two-dimensional optical Bessel potential

Yunji Meng, Youwen Liu, Nanjing Univ. of Aeronautics and Astronautics (China)

Optical spatial solution is a self-trapped beam that exists by virtue of the balance between diffraction and nonlinearity in a Kerr-type media or photorefractive crystal. In this contribution, we studied the existence properties of defect solitons supported by Bessel potentials for different defects. Numerical results show that under different modulation depth for the defect intensity, the existing ranges of defect solitons are different; and the deeper the defect is, the narrower the existence range of the defect soliton is. We found that the stability domain of defect solitons broaden as the defect become shallow. To verify predictions of the above linear stability analysis, the evolution of some typical defect solitons over a certain distance in the medium is obtained by dint of the split step Fourier method.

Influence of magnetic field on fiber Bragg gratings in silica-based fibers at the temperature range 77-293 K

Sergei F. Lyuksyutov, Jeffrey McCausland, The Univ. of Akron (United States)

Optical sensors based on fiber Bragg gratings (FBGs) are capable to measure very accurately temperature, strain, pressure, and acceleration while being immune to external electromagnetic interference. As a part of the graduate student research project an apparatus to interrogate optical sensors with embedded FBGs at the temperatures of liquid nitrogen and above and also at moderate magnetic field (900-8000 G) has been designed at Physics department of UA. The purpose of this work was to study the influence of the magnetic field on the performance of FBSs at the temperature range 77-293 K. Two different wavelengths (514.5 and 488.0 nm) have been used to monitor the state of transmitted light polarization with temperature with the emphasis on Faraday's effect under these conditions. It has been established that strong competition between elliptical and linear states of polarization has occurred and accompanied by increase of the transmitted power (for any polarization) with the peak at the vicinity of 200 K. This anomalous behavior has been compared with LP modal distribution of light at the same temperature range. The composition of the LP modes and their competition is important for understanding physics of thermo-optics and thermal expansion effects in silica-based fibers at low temperatures. Therefore a theoretical analysis of the computer-generated LP modes has been conducted and compared with experimental data.

Dynamic characteristics of two-dimensional finite boundary photorefractive gratings recording and fixing in LiNbO3:Fe crystals

Conglin Lv, Zhijuan Hu, Aimin Yan, Yadong Jin, Huili Chen, Shanghai Normal Univ. (China); Jianfeng Sun, Shanghai Institute of Optics and Fine Mechanics (China)

Nonvolatile photorefractive holographic recording has been widely studied and regarded as the most promising technique for holographic storage, which also has the important potentials in the multifunctional integrated 3-D optical system. However, in practical applications, there still are some crucial problems, such as hologram readout erasing stored information (volatility), low diffraction efficiency, and so on. Fixing the refractive-index grating as one of the key issues for volume holographic memory has become a popular research direction. Thermal fixing is by far the most popular and effective technique for storing nonvolatile photorefractive memories in LiNbO3:Fe crystals. For optimizing the holographic recording in singly doped LiNbO3 crystals, the diffraction characteristics of crossed-beam photorefractive grating are required, and the optimal recording condition should be analyzed. In this paper, some dynamic diffraction characteristics of crossed-beam photorefractive holograms in Fe doped LiNbO3 crystal are studied based on jointly solving the material equations and the two-dimensional coupled-wave theory. The temporal and the spatial evolutions of the refraction index modulation and the diffraction efficiency are given. The spatial variation of the wave intensity is also presented. The influence of the recording conditions, including the optimal recording wavelength, the widths of the recording beams, the width ration of recording beams, and the intensity of recording beams are discussed in detail. We also discussed the dynamic from the recording step to the thermal fixing step. The analysis and observations of this paper will provide some valuable approach to obtaining high persistent diffraction of the nonvolatile holographic storage in doped LiNbO3 crystal.

A novel implementation of optical fiber as converging lens and passive optical clock circuit

Akbar Rahmani-Nejad, Maharan Engineering Corp. (Iran, Islamic Republic of); Ahmad Rahmani-Nejad, Islamic Azad Univ. (Iran, Islamic Republic of); Ali Rahmani-Nejad, Doctor Mosaheb College (Iran, Islamic Republic of)

In this paper we report implementation of optical fiber as converging lens and passive optical generating 100-200 Giga pulses per seconds repetition rate . In brief a tapered fiber having input hole several hundred times greater than output hole and enough length to give enough converging angle that no back scattering occurs, was tested as converging lens. This lens which has output radius of several micrometers can couple and concentrate output beam of a laser to the output. By implementation of hundreds sequences of "1 to n" i.e. ("1*n" optical fiber splitter) the input signal is divided -that can be a giant optical pulse – to "n" output and each time is fed to "n" numbers of output fibers, roughly each output will have intensity of 1/n of input optical pulse and at final stage each branch has only several micrometers length difference in compare with the previous output. This outputs constitute a bundle of hundreds or thousands of micro-fibers then all of these go the reverse stage. All coupled by the same stages of "n to 1" (i.e. n*1 optical couplers). At the final stages due to precise difference length of each branch that makes a delay about several femtoseconds in respect to previous signal, the Output signal will be a sequence of pulses having intensity of equal to (1/ n* number of stages) and repetition rate of thousands of Ghz (Giga pulses per seconds). All non-linear effects during propagation are discussed in the paper.

Multipoint side illuminated absorption based optical fiber sensor

Claudio O. Egalon, Science & Sensors Technologies (United States)

A simple, compact, low cost, multiple point optical fiber sensor for relative humidity (RH) was demonstrated. It has a spatial resolution of 5 mm or better, and can be used for measurements in air, soil, concrete and any other environment where RH is a concern. This sensor uses side illumination of an optical fiber to probe multiple points along the fiber length.

A 1mm diameter glass core fiber and plastic cladding (Thor Labs' BFL48-1000), 25 cm long, was used. Three sections of the original fiber coating and cladding were removed and a polyvinyl acetate solution, with the reversible RH indicator Reichardt's dye, was prepared and applied over these sections creating the sensitive regions. The fiber was mounted over a 20cm long plastic support having three white light LEDs that illuminated each sensing point. The optical signal was coupled into the fiber core and transmitted to a silicon detector located at the fiber tip.

A glove box, model 503 from Electro Technical Systems, connected to a desiccant, an ultrasound humidifier, a control unit and an NIST traceable RH sensor was used for calibration. The light intensity was found to increase linearly with humidity and a resolution of up to 0.15% was obtained.

This concept can be used to design highly dense multi point multi parametric sensors with 200 sensing points, or more, for each meter of fiber. It can be and have been extended to other parameters such as pH, nitrate, phosphate, potassium, magnesium, calcium and others.

Flat optical lens by use of 90-degree volume holographic grating recording geometry and nonvolatile thermal fixing in LiNbO3:Fe crystal

Ya'nan Zhi, Peipei Hou, Jianfeng Sun, Yu Zhou, Liren Liu, Shanghai Institute of Optics and Fine Mechanics (China)

A new design and fabrication of flat optical lens by use of 90-degree volume holographic grating recording geometry is presented. It is recorded by the interference of a plane wave and a spherical wave in a Fe-doped LiNbO3. The flat optical lens can laterally spread and focus the plane wave which perpendicularly incidents on the planar crystal surface. On the basis of the coupled- wave theory of local volume holography. the amplitude distribution and the diffraction efficiency of the diffracted beams are calculated. The optimal switching from recording to thermal fixing is taken into consideration in order to obtain the nonvolatile hologram with maximum fixing efficiency. The flat optical lens has the advantages of light weight, laterally-spreading and focusing, small duty ratio, and easy for the microstructure integration. The testing results measured verify that the flat optical lens can successfully be used for the free space optical communication.

Holographically amplified interferometry with coherent fringe projection for the oil on the water remote sensing and characterization

Nickolai V. Kukhtarev, Tatiana V. Kukhtareva, Alabama A&M Univ. (United States); Arcadi Chirita, Univ. de Stat din Moldova (Moldova)

We suggest combining several optical methods of remote sensing and characterization of crude oil films and emulsions: coherent fringe projection illumination (CFP), holographic in-line interferometry (HILI) with proposed holographic amplification of weak signal images. Combined methods of CFP and HILI are described in the frame of coherent superposition of partial interference patterns. Theoretical approach is illustrated by introducing of the scattering diagrams, describing partial contribution of different interference patterns. We also evaluated different alternative schemes of interferometry with holographic recording and preliminary holographic amplification in photorefractive crystals. Holographic amplification of weak images without phase distortions is possible in a special mode of holographic recording in photorefractive crystals. This preliminary amplification of weak signal beam do not change phase of the signal wave and allow further digital registration and processing with improving signal to noise ratio. Combination of dynamic holographic amplification with digital processing may be especially effective for detection and characterization of weak reflected signals from biological objects. Comparisons of theoretical and experimental results allow finding size of the oil spot and estimating oil film thickness.

3D shape measurements for non-diffusive objects using fringe projection techniques

Wei-Hung Su, Zhao-Kai Wang, National Sun Yat-Sen Univ. (Taiwan)

A scanning approach using fringe projection techniques to perform the 3D profile measurement of a non-diffusive object is proposed. Experimental results are presented that demonstrate the shape measurements of objects with non-diffusive surfaces.

8847-56, Session PMon

Using a phase mask to reduce the depth-of-field of the image acquisition system and its application to 3D shape measurements

Wei-Hung Su, National Sun Yat-Sen Univ. (Taiwan); Nai-Jen Cheng, National Kaohsiung Univ. of Applied Sciences (Taiwan)

In this paper, we present a scanning approach to retrieve the 3D shape of the object with depth height discontinuities. A phase mask is used to reduce the depth-of-field of the image acquisition system. The depth-of-field of the system is so short that only surfaces within the focused area can be clearly observed. By moving the inspected object around the focused area along the depth direction, a set of images which addresses the contour of the object with its corresponding depth is obtained. The

3D shape of the object is retrieved by assembling the image contours with their corresponding depths.

Plasmon-active mixed gratings in volume holographic polymer nanocomposites

Chengmingyue Li, Liangcai Cao, Yao Yi, Qingsheng He, Guofan Jin, Tsinghua Univ. (China)

Holographic data storage technology has been considered as a promising next-generation memory for its unique advantages of large storage capacity and high data transfer rate [1]. With angle multiplexing technology based on Bragg diffraction, thousands of pages of optical information can be superimposed and recorded at a common volume of recording material [2]. In such a memory system, a thick recording material with high diffraction efficiency and low cross-talk noise is key component to achieve large storage capacity. Compared with other types of holographic materials, photopolymer is an optimum material for practical holographic applications due to its high dynamic range, dry real-time processing and low cost [3]. Tremendous efforts have been spent on improving the holographic performances of photopolymer. However, the cross-talk noise induced by the side lobes of angular selectivity is usually unavoidable for the volume holographic grating, which limits the storage capacity in angle multiplexing holographic memory system. It has been known that gold NPs exhibit significant enhancement on absorption due to the collective excitation of conducting electrons known as surface plasmons [4]. In principle, the volume holographic gratings with a modulation of the absorption coefficient can affect the profile of holographic recorded grating. In this letter, we present a novel holographic nanocomposite with the improved holographic diffraction efficiency and suppressed side lobes of angle selectivity by dispersing gold nanoparticles into a bulk holographic photopolymer. The strong absorption grating as a result of redistribution and strongly absorption of gold nanoparticles is activated in phase with the intrinsic refractive index grating. The characteristics of plasmon-active mixed grating are simulated through Kogelnik's coupled wave model. The improved holographic performances are also demonstrated in the volume holographic polymer nanocomposites. It may open up a new way to design the functional holographic material by improving the coupling between the light wave and sub-micrometer patterns.

Time domain modeling of induced birefringence and phase shift in piezoelectric resonance enhanced electrooptic modulators

Robert McIntosh, Amar S. Bhalla, Ruyan Guo, The Univ. of Texas at San Antonio (United States)

In our continuing effort of developing electromagnetic-electromechanical-electrooptic interactive devices, the effect of piezoelectric resonance on the performance of electrooptic modulators is investigated. Time domain finite element models were constructed to determine the phase shift due to the induced birefringence of the device. Two sinusoidal voltage sources are used one to sweep over a range of frequencies while the other setting the modulator at a selected resonance frequency. Ferroelectric single crystals such as $LiNbO_3$ and $(Pb,Zn)NbO_3$-$PbTiO_3$, were examined for their induced index of refraction, the induced phase shift, and the half-wave voltage of given configurations. The time domain model of dual signal ac biased configuration displayed wide bandwidth enhancement when biased at proper resonant modes, which matches well with experimental observations. The results demonstrate the piezoresonant enhancement in terms of low half wave voltage and high electrooptic coefficients in broad frequency ranges. The results also provided corresponding insights that further our understanding on experimental observations reported previously by the authors. The models are suitable for designing of electrooptic device configurations that optimize the properties desired.

A simple optical probing technique for nonlinearly induced refractive index

Partha P. Banerjee, Ujitha A. Abeywickrema, Univ. of Dayton (United States)

Self phase modulation is a nonlinear effects that is observed when a laser beam is focused on to a high-absorbing thermal medium. The refractive index of the medium changes due to the heat generated by the focused laser pump beam. In this paper, self phase modulation is investigated in different ways. An Ar-Ion laser of 514 nm is used as the pump beam and a 632 nm He-Ne laser is used as the probe beam. The probe beam is introduced from the opposite side of the pump beam. Ring patterns are observed from the each side of the sample. Regular far field ring patterns are observed from the pump beam, and two sets of rings are observed with the probe beam. The behavior of these inner and outer rings are monitored for different pump powers. A regular tea sample in a plastic cuvette is used as the nonlinear absorbing sample. The steady state heat equation is solved to obtain an exact solution for the radial heat distribution and far field ring patterns are simulated using the Fresnel–Kirchhoff diffraction integral. Ring patterns are theoretically explained using simulations results, and compared with experimental observations. Finally, an interferometric setup using the low power He-Ne laser is also used to determine the induced change in refractive index. Results are compared with those obtained directly from self-phase modulation and from the probe beam method.

Large-core single-mode trench assisted leaky channel waveguide for high-power applications

Vinita Dhahiya, Than S. Saini, Ajeet Kumar, Delhi Technological Univ. (India); Vipul Rastogi, Indian Institute of Technology Roorkee (India); Ravindra K. Sinha, Delhi Technological Univ. (India)

A suitable waveguide design for high-power laser is one which can support only single- mode for propagation even with a suitably large more area. In this paper we have presented a large-mode-area design in channel waveguide for extended single-mode operation. Proposed design is characterized by a rectangular core and trench assisted cladding. Overall design is leaky and supports a finite leakage loss to all the modes of waveguide. Leaky cladding consists of three trenches of variable depth and thickness. Depth of the trench decreases as one move away from the rectangular core. Proposed design works on the principle of mode filtering. Performance of the waveguide depends upon the leakage losses of the first two modes. We have calculated the leakage loss of the modes using effective-index method. We have made the comprehensive analyses of the trench parameters on the leakage losses of the modes and hence the SM operation. A polymer waveguide with parameters: n1=1.444, n2=1.542, n3 = 1.512, a =5 um, h=10 um, d1=3 um, d2=2 um, d3= 5um introduces 20dB/mm to mode while a nominal loss of 0.20 dB/mm to fundamental mode. Thus, a 1 mm length of waveguide can strip off all higher-order modes to ensure effective single-mode operation with mode area as large as 100 um^2. Dispersive cladding ensures single-mode operation in the wavelength range 750-1600 nm. Proposed waveguide can be fabricated in polymer geometry by reactive-ion etching technique and is expected to find applications in designing high-power lasers.

Selectively filled large-mode-area photonic crystal fiber for high power applications

Than S. Saini, Ajeet Kumar, Delhi Technological Univ. (India); Vipul Rastogi, Indian Institute of Technology Roorkee (India); Ravindra K. Sinha, Delhi Technological Univ. (India)

In the last decades photonic crystal fibers (PCFs) remained exciting research topic because of their unique features such as endlessly single mode, dispersion tailoring, high birefringence, large mode area etc. Among these features of PCFs large mode area (LMA) is most important because it support high power transmission in the fiber lasers, fiber amplifiers and other high power applications. The limitations of high power devices are the nonlinear effects and the low threshold frequency value. These limitations may be overcome by using fiber with large mode area that can maintain single mode operation. In this work we have proposed a PCF design in which the center air hole has been removed and the six air holes near the center core are filled with high refractive index material. To analyse the design we have used Finite Element Method. Transmission characteristics of PCF such as effective mode area, single-mode operation and bending performance of the fiber have been investigated for varying the geometrical parameters. Selectively filled material of refractive indices, nfill, 1.451 and 1.4515 has been chosen to analyse the performance of the proposed design. Spectral performance of the design has also been investigated for both the filling material. Effective mode area of the fundamental mode increase with the wavelength. Proposed design with nfill = 1.451 show 835 um^2 mode area at 1.064 um with a nominal loss of 1.0e-4 dB/m at 10 cm bending radius. Such fiber can be a good candidate for design of high-power applications.

Electronic phase transitions in transparent zinc oxide thin films

Armen R. Poghosyan, Natella R. Aghamalyan, Institute for Physical Research (Armenia); Ruyan Guo, The Univ. of Texas at San Antonio (United States); Yvgenia A. Kafadaryan, Ruben K. Hovsepyan, Institute for Physical Research (Armenia)

Metal?dielectric electronic phase transitions in wide gap ZnO semiconductors have been studied. The influence of defect complex caused by oxygen vacancy and interstitial zinc atom on the metal-dielectric transition is considered. The peculiarities of this transition in ZnO films doped by donor or acceptor impurity and the influence of mentioned defect complex on the charge carrier transfer mechanism were investigated. The control parameter of this transition is the concentration of Zn interstitial atom. The films with high concentration of Zn interstitial atom have high conductivity of metallic type. Air annealing leads to conductivity decreasing and to change of conductivity temperature dependence from metallic type to semiconductor (dielectric) one.

Tomographic study of polymer bridges between two optical fibers for telecommunication applications

Michal Dudek, Malgorzata Kujawinska, Aneta B. Michalska, Warsaw Univ. of Technology (Poland); Heidi Ottevaere, Vrije Univ. Brussel (Belgium); Vincent Parat, Brahim O. Dahmani, Gregory Baethge, LovaLite (France)

The most common methods of optical fibers joining are fusion splices and mechanical splices with refractive index-matching gel between the fibers ends. A new, simple method of manufacturing micrometer-sized polymer waveguides – bridges – between two optical fibers, which has been reported a few years ago, could greatly improve mechanical splicing efficiency. A drop of a liquid photopolymerizable formulation is deposited between two cleaved fibers and the polymerization process is induced by the light that emerges from one of the fibers. Waveguide effect inside the polymer creates a stable connection between fibers' cores. After removing the excess of unpolymerized formulation, another type of photopolymerizable solution is introduced to the splicing area to create protection cladding.

Investigation of the detailed index profile obtained allows to describe the light propagation in the waveguide and to deduce its performances: insertion losses and reflection losses of the bridge.

In this paper we present studies of interferometric tomography used to determine the refractive index distribution in the polymer bridges.

Detailed refractive index maps are needed in order to improve the technological process of manufacturing those bridges and achieve lower reflection losses. Our investigations are performed in several stages.

At first the insertion and reflection losses are measured to check if the bridges have the assumed optical properties. The next step is to perform full tomographic measurements in a Mach-Zehnder based interferometric tomography setup for both bridges and reference fibers used to produce those bridges. The latter provides refractive index distributions and profiles. Based on these data we use several commercial modeling tools in order to obtain reflection and insertion losses. The obtained values will then be compared to those obtained by usual reflectometry.

8847-65, Session PMon

In addition of acousto-optic devices' piezoelectric transducers design issue

Ruslan A. Hansuvarov, Oleg V. Shakin, St. Petersburg State Univ. of Aerospace Instrumentation (Russian Federation)

Acousto-optic device are used in various signal processing systems and laser radiation controlling systems. These systems allow the wideband signals processing in real-time and high-speed laser beam scanning.

The main technical difficulties caused by technological problems of its production, such as attaching the piezoelectric transducer for efficient excitation of acoustic waves in crystals in the range of 100-1000 MHz.

In this range there usually use a lithium niobate crystal plates as the active piezoelectric excitation of longitudinal waves or shear waves, and thin films of zinc oxide there usually use for the higher-frequency acousto-optic devices.

It is shown that it is possible to choose slices of piezoelectric transducers for some devices that will generate both types of oscillation, L and S simultaneously. It is Y +12° and Y +137° slices. Also this article shows that for reducing the level of excitation of parasitic oscillations requires high accuracy of the crystallographic orientation of the plates.

In this paper, dependences of electromechanical coupling coefficient for different slices of a lithium niobate crystals are calculated. They illustrate the validity of selecting the appropriate cut for the piezoelectric transducer for the excitation of longitudinal waves and shear waves in acousto-optic cells.

Also, these dependences determines the criteria for the accuracy of the technological requirements for the piezoelectric plate transducers constructing.

8848-1, Session 1

Two-dimensional sub-5 nm hard x-ray focusing with MZP

Markus Osterhoff, Matthias Bartels, Florian Döring, Christian Eberl, Sarah Hoffmann, Tobias Liese, Volker Radisch, Anna-Lena Robisch, Aike Ruhlandt, Felix Schlenkrich, Tim Salditt, Hans-Ulrich Krebs, Georg-August-Univ. Göttingen (Germany)

To date, sub-10 nm focusing has been achieved using Multilayer mirrors, and sub-50 nm focusing is routinely achieved using Multilayer zone plates and Multilayer mirrors. Numerical simulations of optimised focusing devices reach below the 1 nm scale.

Here, we show that a combined optic of a large-aperture Kirckpatrick-Baez mirror system in conjunction with small focal lengths of a multilayer zone plate, enables two-dimensional focusing below 5 nm (FWHM).

The concept preserves the benefits, while overcoming the limitations, of two schemes: KB mirrors offer large accepting apertures of the incoming X-ray beam, but have a large focal length; MZPs are very compact with focal distances in the micrometre range.

Therefore, aperiodic W/Si multilayers were pulsed laser deposited (PLD with high quality on a W wire with single layer thickness down to 5.1 nm. From the coated wire, a lens of thickness 700 nm was fabricated by cutting using focused ion beam (FIB). X-ray focusing experiments were performed at the coherence beamline P10 of PETRA III at a photon energy of 7.9 keV, corresponding to a wavelength of ?=0.159 nm.

In a first demonstration experiment we recorded far-field diffraction patterns that are consistent with a 2D focus of 4.3 nm x 4.7 nm, with a focusing efficiency of approximately 1 %; forward simulations including error models based on measured deviations, auto-correlation analysis and three-plane phase reconstruction are in good agreement.

8848-2, Session 1

Development of ultra-precise piezoelectric deformable mirrors for x-ray nanofocusing

Hiroki Nakamori, Satoshi Matsuyama, Shota Imai, Takumi Goto, Osaka Univ. (Japan); Takashi Kimura, Hokkaido Univ. (Japan); Yasuhisa Sano, Osaka Univ. (Japan); Yoshiki Kohmura, Kenji Tamasaku, Makina Yabashi, Tetsuya Ishikawa, RIKEN (Japan); Kazuto Yamauchi, Osaka Univ. (Japan)

We designed and fabricated a piezoelectric deformable mirror without high-spatial-frequency deformation errors. To investigate the performance of the developed deformable mirror, the deformation accuracy was evaluated when the mirror was deformed to an elliptical shape. A peak-to-valley deformation accuracy of 2 nm was achieved. In addition, to investigate its focusing performance, we performed a two-dimensional focusing test at SPring-8. As a result, a focus spot size of 300 nm (H) x 490 nm (V) was realized.

8848-3, Session 1

Thin crystal development and applications for hard x-ray free-electron lasers

Taito Osaka, Osaka Univ. (Japan); Makina Yabashi, RIKEN (Japan); Yasuhisa Sano, Osaka Univ. (Japan); Kensuke Tono, Japan Synchrotron Radiation Research Institute (Japan); Yuichi Inubushi, Takahiro Sato, RIKEN (Japan); Satoshi Matsuyama, Osaka Univ. (Japan); Tetsuya Ishikawa, RIKEN (Japan); Kazuto Yamauchi, Osaka Univ. (Japan)

Development of thin crystals, which can be utilized as beam splitters for the hard x-ray regime, is important for expanding the range of applications of hard x-ray free-electron laser (XFEL) sources. In particular, a beam splitter is used to construct a split and delay unit, which produces two replica XFEL pulses with a time delay from femtosecond to nanosecond, and to provide a dedicated branch for photon diagnostics. To function as a beam splitter, the crystal device has to be a perfect single crystal with a thickness from a few to 20 µm to obtain high reflectivity and transmissivity, simultaneously. Fabrication of the crystal is difficult with conventional methods. We developed a new method to fabricate a thin silicon crystal based on a reactive dry etching method using atmospheric-pressure plasma. Owing to the high pressure, ions in the plasma have low kinetic energy, which suppress to induce lattice strains. Another advantage of this method is a capability to etch the silicon target isotropically with a processing speed that is independent of crystal orientations [e.g., (111) or (511)]. Using this method, we succeeded in fabrication of sub 10-µm-thick Si crystals. High crystalline perfection of the crystals was verified with topographic and diffractometric methods using coherent x-rays at the 1-km-long beamline BL29XU of SPring-8. We report the results and several applications of the thin crystals at SPring-8 Angstrom Compact free-electron LAser (SACLA).

8848-4, Session 1

Design of novel x-ray optical system for rocket experiment

Ladislav Pina, Czech Technical Univ. in Prague (Czech Republic); Adolf J. Inneman, Rigaku Innovative Technologies Europe (Czech Republic); René Hudec, Astronomical Institute of the ASCR, v.v.i. (Czech Republic); Vladimir Tichy, Czech Technical Univ. in Prague (Czech Republic); Webster Cash, Univ. of Colorado at Boulder (United States); Veronika Marsikova, Daniela Cerna, Rigaku Innovative Technologies Europe (Czech Republic)

In this work, a novel design of X-ray optical system for astrophysical rocket experiment is investigated. The proposed system is based on four modules with Kirkpatrick-Baez (KB) configuration allowing usage of multi-foil mirrors arranged to parabolic profile. The KB modules are supplemented by rotationally symmetrical parabolic segments. This X-ray optical system effectively uses a circular aperture. The KB modules are placed in four quadrants while the segments are set into a Cartesian cross between the KB modules. The proposed optical system could be used within a student rocket experiment of University of Colorado that should verify function of NIST's energy-dispersive detector based on Transition Edge Sensors (TES microcalorimeters).

8848-5, Session 1

High-speed photon energy tuning of x-rays with high duty cycle by use of clessidra prism arrays

Werner H. Jark, Sincrotrone Trieste S.C.p.A. (Italy)

Clessidra x-ray lenses are formed of many tiny prisms in rows, which are arranged in the form of a large prism. Such objects can focus x-rays by refraction when the number of prisms increases appropriately with increasing distance from the lens optical axis. The refractive index of matter for x-rays varies rapidly with photon energy, and consequently these objects focus chromatically. They can thus even act as monochromators in combination with slits in the focal plane, as was shown by Liu et al (J. Synchrotron Rad. 19, 191–197 (2012)). The simplest energy tuning is achieved, when the exit slit is moved longitudinally along the beam trajectory. As this is inconvenient, Jark (J. Synchrotron Rad. 19, 492-496 (2012)) proposes the photon energy tuning in a fixed slit by varying the azimuthal orientation of the structure, or its yaw angle, with respect to the incident x-ray beam. This will then require a wider prism structure. Now the symmetry of the clessidra structure can very favorably be used for the construction of a high speed monochromator with very efficient duty cycle. The lens structures are rather small with dimensions of the order of 1 mm in height and 25 mm in width and in length, and can thus easily be rotated in yaw with high speed. This contribution will discuss various options of this operation scheme.

8848-6, Session 2

Hard x-ray nanofocusing with refractive x-ray optics: full beam characterization by ptychographic imaging

Christian G. Schroer, Frank Seiboth, Technische Univ. Dresden (Germany); Andreas Schropp, Technische Univ. Dresden (Germany) and SLAC National Accelerator Lab. (United States); Susanne Hönig, Robert Hoppe, Jens Patommel, Sandra Stephan, Technische Univ. Dresden (Germany); Gerd Wellenreuther, Gerald Falkenberg, DESY (Germany); Sebastian Schöder, Synchrotron SOLEIL (France); Manfred Burghammer, European Synchrotron Radiation Facility (France)

Hard x-ray scanning microscopy relies on small and intensive nanobeams. Refractive x-ray lenses are well suited to generate hard x-ray beams with lateral dimensions of 100 nm and below. We have used both rotationally parabolic refractive x-ray lenses made of beryllium and nanofocusing refractive x-ray lenses (parabolic cylinders) made of silicon to focus hard x-rays between 8 and 25 keV to (sub-)100 nm dimensions. With rotationally parabolic refractive x-ray lenses, a lateral full-width at half maximum (fwhm) extension of 125 to 400 nm was achieved, showing consistently the dependence of diffraction limited focus size and depth of focus on the aperture of the optic. With nanofocusing refractive x-ray lenses, beam sizes down to 46 nm were achieved. The nanobeams were fully characterized by ptychographic scanning coherent diffraction imaging, giving access to the full complex wave field in the focus with unprecedented accuracy and sensitivity. From these data, we can reconstruct the caustic along the optical axis and determine the aberrations of the x-ray optics. By verifying the consistency of several independent wave field measurements along the optical axis, we address the question of how well the reconstruction represents the nanobeam. With a single ptychogram the wave field can be properly determined over a large range along the optical axis, also at positions inaccessible otherwise.

8848-7, Session 2

X-ray tomography of high-pressure fuel spray by polycapillary optics

Luca Marchitto, Istituto Motori CNR (Italy); Sultan B. Dabagov, Istituto Nazionale di Fisica Nucleare (Italy) and P.N. Lebedev Physical Institute (Russian Federation); Luigi Allocca, Istituto Motori CNR (Italy); Dariush Hampai, Istituto Nazionale di Fisica Nucleare (Italy); Salvatore Alfuso, Istituto Motori CNR (Italy)

In this paper the structure of a gasoline spray from an automotive GDI injection system has been studied by means X-ray Tomography.

The study of transient high pressure fuel sprays by X-ray based techniques is worldwide diffused. Synchrotron radiation is successfully exploited for this aim because of its high intensity and pulsed nature. However top-table application are unusual.

This work reports the results obtained by performing desktop experiments using an 8 keV Cu K∞ X-ray. Polycapillary semilens shaped the divergent X-ray beam into quasi-parallel one allowing to focus the radiation on the investigated spray region. High contrast focus images were collected by a CCD detector for X-radiation.

A 6-hole GDI injector has been coupled to the high pressure pump by a specially designed rotating device able to work up to 25MPa. X-ray absorption measurements have been performed with angular steps of 1° at the injection pressure of 12.0 MPa. The sinogram reconstruction of the jets by slices permitted to get information about the inner structure of the fuel spray downstream the nozzle tip, where conventional optical techniques are inhibited. A 3D spatial distribution of the fuel emerging from the injector has been obtained. The data have been used to perform spray density measurements. The results concerning the density profile along the fuel jets axis and the cross section distribution at different distances from the nozzle have been reported.

8848-8, Session 2

Sagital focusing-inducing energy structure in medium- to high-energy resolution x-ray monochromators

Marcelo G. Honnicke, UNILA (Brazil); Fabio Masiello, PANalytical B.V. (Netherlands); Steven N. Ehrlich, Brookhaven National Lab. (United States); Edson M. Kakuno, UNIPAMPA (Brazil); Yong Q. Cai, Brookhaven National Lab. (United States); Jurgen W. Hartwig, European Synchrotron Radiation Facility (France)

Sagital focusing is widely used geometry to focus horizontally X-rays in synchrotron beamlines. Usually, two types of devices are used: toroidal mirrors combined with flat X-ray monochromators or flat mirrors combined with sagital focusing monochromators. The former option seems to be better since the stresses caused bending the second crystal in a double crystal monochromator (DCM) is avoided. In this work we exploit the effect of the sagital focusing in the medium to high energy resolution X-ray monochromators. Our studies are based on theoretical explanation of experimental data acquired into two different experiments made at XRD2 beamline at Laboratorio Nacional de Luz Sincrotron (LNLS / Brazilian Synchrotron) and X18A at National Synchrotron Light Source (NSLS / BNL / USA). The first experiment was carried out with a flat meridional bendable mirror followed by a DCM with the second crystal being sagitally bent. The second experiment was carried out with a flat Si 111 DCM followed by a toroidal, but meridional bendable mirror. Both setups are completed by a Si 551 4-bounce monochromator to scan the energy spectrum around 13.7 keV and 13.9 keV, respectively. The results show that the sagital curvature induces an energy structure. Theoretical studies made by analyzing the reflecting angles in the mirror surface joined with the dynamical theory of X-ray diffraction in the 4-bounce X-ray monochromators confirm these results which are also exploited by Dumond diagram analysis.

8848-9, Session 2

Modeling of compound refractive lens using Zemax software

Mikhail A. Antimonov, Univ. of Illinois at Chicago (United States) and Argonne National Lab. (United States); Ali Khounsary, Sarvjit D. Shastri, Argonne National Lab. (United States); Farzad Mashayek, Univ. of Illinois at Chicago (United States)

Compound refractive lenses (CRLs) developed over the past 20 years have successfully been used for 1D and 2D focusing of X-ray beams at synchrotron radiation facilities.

For an ideal CRL system, the focal distance, focus size, transmission, and the gain can be estimated using simple analytical formulations (e.g., the thin lens approximation). However, numerical techniques such as ray tracing may have to be employed to determine the impact that the lens (its imperfection, thickness, location, alignment) or the source (size, shape, properties) may have on the lens system performance.

In this paper the ray tracing software Zemax is used to analyze the performance of 'real' CRL systems with curved and saw tooth geometries, and investigate the impact of the aforementioned factor on their performance. The optimal design of a saw-tooth CRL for focusing a high energy X-ray beam is described, and experimental results are provided.

Work is supported by the U.S. Department of Energy, Office of Science, Contract No. DE-AC02-06CH11357.

8848-10, Session 3

K-B bendable system optimization at FERMI@ Elettra FEL: impact of different spatial wavelengths on the spot-size

Lorenzo Raimondi, Cristian Svetina, Nicola Mahne, Sincrotrone Trieste S.C.p.A. (Italy); Daniele Cocco, SLAC National Accelerator Lab. (United States); Flavio Capotondi, Emanuele Pedersoli, Maya Kiskinova, Sincrotrone Trieste S.C.p.A. (Italy); Barbara Keitel, Guenter Brenner, Elke C. Plönjes-Palm, Deutsches Elektronen-Synchrotron (Germany); Tobias Mey, Klaus Mann, Laser-Lab. Göttingen e.V. (Germany); Marco Zangrando, Sincrotrone Trieste S.C.p.A. (Italy) and Consiglio Nazionale delle Ricerche (Italy)

FERMI@Elettra, the first seeded EUV-SXR free electron laser (FEL) user facility, located at Elettra- Sincrotrone Trieste S.C.p.A., is under advanced commissioning. The Diffraction and Projection Imaging (DiProI) is one of the three beamlines already operative at FERMI@Elettra. It employs a Kirkpatrick-Baez (K-B) active X-ray optics system in order to focus the FEL beam on the sample inside the endstation. The aim of the present work is to characterize this optical system in order to improve and optimize its performances in terms of quality and size of the focal spot, and consequently of fluence. To this end, we performed a campaign of measurements with several diagnostic systems, including a wavefront sensor mounted after the DiProI chamber. Online wave- front measurements allow for optimizing the bending acting on the mirrors' curvature and the angle positions (pitch, roll, and incidence angle) of the K-B system. We have also compared the measurement results with the predictions from simulations obtained using the WISE code, starting from mirror actual surface metrology characterization. By filtering the Fourier transform of the mirror surface profiles we have analyzed the impact of different spatial wavelengths on the focal spot degradation. From wavefront measurements we have inferred a focal spot of 10 µm x 13.5 µm confirmed by the PMMA ablation. The results from simulations with the WISE code are in agreement with the measurements and show, for different energies of the incident beam, the threshold below which the spatial wavelengths of the K-B mirror surfaces start to have no influence on the focal spot degradation.

8848-11, Session 3

Fabrication of ellipsoidal focusing mirrors for soft x-ray microscopy using elastic emission machining and electroforming

Yoshinori Takei, Takehiro Kume, Hidekazu Mimura, The Univ. of Tokyo (Japan)

Ellipsoidal mirror is one of promising soft X-ray focusing optics, because soft X-rays can be focused to nanometer dimension with very large aperture, long focal length and no chromatic aberration. However, the a nanometer focused beam size was not achieved. The reason is that there is no fabrication method of the inner surface with nanometer accuracy, in particular, when the diameter is less than several millimeters. We have been researching on manufacturing process of an ellipsoidal mirror for soft X-ray focusing. In this process, the master surface is fabricated through several steps consisting on grinding, polishing and Elastic Emission Machining (EEM). EEM can finish the surface shape with a controllability of 0.1 nm and the surface roughness less than 0.2 nm (RMS). Then the shape of ellipsoidal mirrors is produced by replicating the master surface using an ultra-precise Ni electroforming method. The electroforming is performed under a room temperature and the inner stress of the deposited film is adjusted to be extremely small by controlling electric potential on the films to realize high replication accuracy. In this paper, we report the current status in developments of EEM and electroforming processes specialized for ellipsoidal mirrors.

8848-12, Session 3

Two-foci bendable mirrors for the ALS MAESTRO beamline: design and metrology characterization and optimal tuning of the mirror benders

Nikolay A. Artemiev, Ken P. Chow, Daniel J. Merthe, Eli Rotenberg, Jeffrey H. Takakuwa, Tony Warwick, Valeriy V. Yashchuk, Lawrence Berkeley National Lab. (United States)

MAESTRO, the Microscopic and Electronic STRucture Observatory, currently in the construction phase at the ALS, will be a world premier facility for the study of electronic and structural properties of in situ grown crystals. The new facility will be comprised of several end-stations, including angle-resolved photoemission spectroscopy (ARPES), sample sizes > 10 µm (µARPES end-station), sample sizes > 50 nm (nARPES end-station), and a photoemission electron microscope combined with a low-energy electron microscope (PEEM/LEEM). Redirection of the x-ray beam between the µARPES and PEEM/LEEM end-stations, which are longitudinally separated by 2.5 meters, uses a system of two bendable mirrors, placed in Kirkpatrick-Baez configuration. Here we present the details of the mirrors' design and report on the characterization of the mirrors carried out at the ALS optical metrology laboratory (OML). Optimal tuning and calibration of the mirrors was performed using a technique based on regression analysis of surface slope data obtained with a slope measuring long trace profiler (LTP) recently developed at the OML [Opt. Eng. 48(8), 083601 (2009)]. We provide results of tests of temporal and temperature stabilities of the shape of the mirrors. High reliability of the optical metrology with the mirrors has become possible due to a modification of the tuning procedure described in the present article. The modification allows accounting for the gravity sag effect, as well as the LTP systematic error in measurements with significantly curved x-ray optics. This work is supported by the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

8848-13, Session 3

Optical design of two-step soft x-ray focusing system with rotationally symmetric mirrors

Hiroto Motoyama, Hidekazu Mimura, The Univ. of Tokyo (Japan)

Nano-focusing technique with high efficiency is required for high spatial resolution and high detection sensibility in various soft X-ray analysis methods. Rotationally symmetric-shape mirror, like an ellipsoidal mirror or a Wolter mirror, is the ideal focusing optics from the viewpoints of advantages of large aperture, long focal length and no chromatic aberration. However, there are a few problems when these mirrors will be installed to a synchrotron beamline. The beam size of incident soft X-rays from the source is too small to illuminate the entire surface, which denotes that the numerical aperture decreases and soft X-rays cannot be focused to the desired size. To solve this problem, we propose two-stage focusing system using a free-form grazing incidence mirror and a rotationally symmetric mirror for expanding and focusing, respectively. Generally, the X-ray beam propagating at the central region of the rotationally symmetric mirror cannot be utilized. In the proposed optical system, the soft X-ray beam reflected by the upstream mirror is focused with a ring-shaped intensity distribution on the focal plane and expanded with dark area at the center to illuminate the entire surface of downstream

mirror with no loss of photons. As the results, soft X-rays can be focused with high numerical aperture with high efficiency. The degree of freedom against the geometrical limit is also further increased in optical designs. This paper reports a design procedure to determine the shape of both mirrors and results of ray tracing and wave optical simulations at water window wavelength ranges.

8848-14, Session 3

Dual focusing for hard-x-ray inelastic scattering

Daisuke Ishikawa, Hiroshi Uchiyama, Japan Synchrotron Radiation Research Institute (Japan) and RIKEN (Japan); Satoshi Tsutsui, Japan Synchrotron Radiation Research Institute (Japan); Hiroshi Fukui, Univ. of Hyogo (Japan) and RIKEN (Japan); Alfred Q. R. Baron, RIKEN (Japan) and Japan Synchrotron Radiation Research Institute (Japan)

We use a combination of a bent cylindrical mirror and short (15 and 20 cm) elliptically polished Kirkpatrick-Baez (KB) mirrors to efficiently focus the entire beam from an insertion device for flux-limited inelastic x-ray scattering experiments at energies up to 26 keV. This system is in regular use at SPring-8 BL35XU. Use of only the bent cylinder, 10 meters from the sample, provides a small spot, ~70 microns diameter, with good, ~0.35 mrad, collimation and nearly 100% throughput over an acceptance of more than 4 x 1.5 mm2 in most experiments. Insertion of an additional KB pair, without moving the sample position, reduces the spot size to 16 microns, for samples where a smaller spot size is desirable, even at the expense of poorer momentum resolution, due to increased divergence. The KB pair employs fixed elliptically polished mirrors and pre-focusing from the cylindrical mirror is used to realize a relatively inexpensive setup that retains high (~50%) throughput compared to the full ID beam, even at energies above 20 keV. Design considerations, and the setup, and the performance of the system will be discussed, including the choice of elliptical KB mirrors instead of hyperbolic mirrors, and the strict limits set by requiring large (180 mm) free space upstream of the sample position.

8848-15, Session 4

X-ray mirror metrology using SCOTS/ deflectometry

Run Huang, Peng Su, James H. Burge, College of Optical Sciences, The Univ. of Arizona (United States); Mourad Idir, Brookhaven National Lab. (United States)

SCOTS is a high precision slope measurement technology based on deflectometry. Light pattern on a LCD display illuminates the test surface and its reflected image is used to calculate the surface slope. SCOTS provides a high dynamic range full field measurement of the optics without null optics required.

In this paper, we report SCOTS tests on x-ray mirrors to sub nm level with precise calibration of the test system. A LCD screen with dots/check board pattern was aligned into the system at the test mirror position to calibrate camera imaging distortion in-situ. System errors were further eliminated by testing and subtracting a reference flat which was also aligned at the same position as the test mirror. A virtual reference based on the ideal shape of the test surface was calculated and subtracted from the test raw data. This makes the test a 'virtual null' test. Better than 0.1nm rms precision and sub nm rms accuracy were achieved on a super polished elliptical mirror (90mm in its long end). The test accuracy is limited by the shape errors in the reference flat.

In comparison with sub-aperture stitching interferometry and long trace profilometer (LTP), commonly metrology used for X-ray optics, SCOTS provides a full-field measurement solution and comparable precision. Moreover, high dynamic range is another advantage in SCOTS. SCOTS test can easily accommodate to measure much steeper aspheric or free-form surfaces.

8848-16, Session 4

Application of time-invariant linear filter approximation to parameterization of one- and two-dimensional surface metrology with high-quality x-ray optics

Valeriy V. Yashchuk, Lawrence Berkeley National Lab. (United States); Yuri N. Tyurin, Moscow State Univ. (Russian Federation) and Second Star Algonumerics (United States); Anastasia Tyurina, Scientific Systems Co., Inc. (United States)

Numerical simulations of the performance of new x-ray beamlines and those under upgrade require sophisticated and reliable information about the expected surface slope and height distributions of prospective beamline optics before they are fabricated. Ideally, such information has to be based on metrology data obtained with existing optics, which are fabricated by the same vendor and technology, but generally, with different sizes, and slope and height rms variations. In a recent work [Opt. Eng. 51(4), 046501, 2012], it has been demonstrated that autoregressive moving average (ARMA) modeling of one-dimensional (1D) slope measurements with x-ray mirrors allows a high degree of confidence when fitting the metrology data with a limited number of parameters. With the parameters of the ARMA model, the surface slope profile of an optic with the newly desired specification can reliably be forecast. Here, we investigate the time-invariant linear filter (TLF) approach to optimally parameterize surface metrology of high quality x-ray optics thought of as a stationary uniform random process. We show that the TLF approximation has all advantages of one-sided AR and ARMA modeling, but it additionally gains in terms of fewer filter parameters and better spectral accuracy. Moreover, the suggested TLF approach can be directly generalized to 2D random fields. This work is supported by the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

8848-17, Session 4

Correlation analysis of systematic errors in surface metrology with a slope profiler

Valeriy V. Yashchuk, Nikolay A. Artemiev, Lawrence Berkeley National Lab. (United States)

We describe, and present the mathematical foundation for, a novel method for the elicitation and suppression of contributions to systematic errors of surface slope profiler metrology. The method consists of the randomization of the systematic error by the averaging of multiple measurements, specially arranged to mutually anti-correlate. We also discuss the possibility to apply correlation analysis to the entire residual surface slope distribution in order to find anti-correlation parameters of the distribution. In this case, repeated measurements with the corresponding change of the experimental arrangement (position of the surface and/or its overall tilt) can be used to identify the origin of the observed anti-correlation features by analyzing the difference between the measurements. If the corresponding minimum of the auto-correlation function is due to a systematic error, averaging over the repeated measurements will provide an efficient suppression of the systematic error. If the observed anti-correlation properties are due to the polishing process, and therefore belong to the surface itself, we suggest that the possibility of re-polishing the surface based on the correlation analysis be considered. Throughout the present work we have discussed correlation analysis of surface slope metrology data. However, a similar consideration can be applied to surface topography in the height domain measured with other metrology instrumentation, for example: interferometers and interferometric microscopes. This work is supported by the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

8848-18, Session 4

Surface metrology of off-axis paraboloids with a Zygo phase-measuring interferometer

Wayne R. McKinney, Nikolay A. Artemiev, Gregory Y. Morrison, Valeriy V. Yashchuk, Howard A. Padmore, Lawrence Berkeley National Lab. (United States)

Increased brightness of updated 3rd generation synchrotron sources and FELs leading to smaller focused spots of x-rays has led optical designers to consider more and different methods of manufacture, and more and different figures for optical surfaces [Opt. Express. 17(20), 18271-18278, 2009]. The desire to achieve higher resolving powers for Resonant Inelastic X-ray Scattering (RIXS) also drives the interest in shapes which can focus to a point in monochromator designs. As a run up to potential future requirements in soft x-ray optical metrology, we investigate here the surface quality of off-axis paraboloids fabricated by diamond-turning. A novel method to measure off-axis parabolic optics is based on using gold microspheres as a diffraction limited back reflector in a double-bounce auto collimating geometry [SPIE Proc. 7102, 71020X (2008)]. We also discuss two other minor modifications to this experimental approach and compare them with the one using a diffraction limited ball to measure off-axis parabolic optics. Such methods may be extended, we propose, to ellipsoidally figured optics using converging rather than parallel light emerging from the interferometer.

8848-19, Session 4

Status of multi-beam long trace-profiler development

Mikhail V. Gubarev, Kiranmayee Kilaru, Brian Ramsey, NASA Marshall Space Flight Ctr. (United States); Wayne R. McKinney, Daniel J. Merthe, Lawrence Berkeley National Lab. (United States); Peter Z. Takacs, Brookhaven National Lab. (United States); Valeriy V. Yashchuk, Lawrence Berkeley National Lab. (United States)

The multi-beam long trace profiler (MB-LTP) is under development at NASA's Marshall Space Flight Center. The traditional LTPs scans the surface under the test by a single laser beam directly measuring the surface figure slope errors. While capable of exceptional surface slope accuracy, the LTP single beam scanning has slow measuring speed. Metrology efficiency can be increased by replacing the single laser beam with multiple beams that can scan a section of the test surface at a single instance. The increase in speed with such a system would be almost proportional to the number of laser beams. The progress for a multi-beam long trace profiler development will be presented.

8848-20, Session 5

Multilayer-based solutions for Extreme UV light with enhanced spectral purity

Viacheslav Medvedev, FOM Institute DIFFER (Netherlands)

We report on the development of multilayer based solutions to enhance the spectral purity of EUV light generated by plasma-based sources. These multilayer systems simultaneously reflect EUV radiation and suppress infrared (IR), e.g. scattered CO_2 laser radiation of the laser-produced plasma EUV sources. Two possible solutions are compared.

The first solution is the hybrid mirror that acts as an efficient Mo/Si Bragg reflector for EUV radiation at a given wavelength and simultaneously possesses spectral-selective suppression of the specular reflectance for unwanted infrared (IR) radiation due to the grating phase-shift resonance. Suppression of 70x factor is demonstrated for specular reflectance of IR radiation together with 61% EUV peak reflectance at 13.5 nm.

The second solution consists of an IR-transparent B_4C/Si multilayer stack which is used both as EUV-reflective coating and as a phase shift layer of the resonant IR antireflective (AR) coating. Suppression of more than two orders of magnitude at the target wavelength is demonstrated. The currently achieved EUV peak reflectance is about 45% at 13.5 nm.

8848-21, Session 5

Suppression of long wavelength reflection from Extreme-UV multilayer optics

Qiushi Huang, Viacheslav Medvedev, A. J. R. van den Boogaard, Robbert W. van de Kruijs, Sebastiaan P. Huber, FOM Institute DIFFER (Netherlands); Eric Louis, Fred Bijkerk, FOM Institute DIFFER (Netherlands) and Univ. Twente (Netherlands)

Plasma based radiation sources optimized to emit 13.5 nm Extreme UV radiation also produce a significant amount of light at longer wavelengths. This so called out-of-band (OOB) radiation is detrimental for the imaging capabilities of an EUV lithographic imaging system, in particularly the deep ultraviolet (DUV) and ultraviolet (UV) parts of the light (λ=100-400 nm).

To suppress these wavelengths, while maintaining the high efficiency of the mirror for EUV, several methods have been developed, including phase-shift gratings (PsG) and spectral-purity-enhancing (SPE) layers. PsGs use the diffraction property of a quarter-wavelength high multilayer grating to filter out the DUV/UV light, while the SPE layer works as an anti-reflection coating. Both methods have achieved a suppression factor of 10~30 around the target wavelength. To estimate the integral suppression of DUV/UV dose and the spectral characteristics in a real system, a typical laser produced plasma (LPP) source emission spectrum was included in the analysis. Different structures were optimized to obtain the highest integral suppression of the DUV/UV dose and these results are presented.

8848-22, Session 5

Reflectance of multilayer coatings for the lithography generation beyond EUVL

Eric Louis, FOM Institute DIFFER (Netherlands) and Univ. Twente (Netherlands); Igor A. Makhotkin, Erwin Zoethout, FOM Institute DIFFER (Netherlands); Stephan Müllender, Carl Zeiss SMT GmbH (Germany); Fred Bijkerk, FOM Institute DIFFER (Netherlands) and Univ. Twente (Netherlands)

Lithography based at 6.x nm wavelength is considered to be a potential extension of the current 13.5 nm EUV lithography.

On its development path it will meet significant challenges such as availability of a suitable source, resist, mask, and multilayer optics.

The topic of this paper is the possible improvement of La/B- based multilayers for the 6.5 to 7.0 nm wavelength range. The requirements for the multilayers are challenging: the current best achieved reflectivity ~ 50 % is significantly lower than desired ~ 70+ %.

Nitridation of La partly suppresses material inter-diffusion, resulting in 47% reflectance at normal incidence for LaN/B_4C multilayers at 6.6 nm, without any deposition process optimization. At off-normal angle experiments the multilayers with a larger bi-layer thickness show a reflectivity of 70% at 6.6 nm because of low influence of the interfaces on the reflectance. This value is close to the theoretical maximum.

The following possibilities to improve the normal incidence reflectance are identified and include:

- optimization of the nitridation of La,
- reduction of the interface roughness
- replacement of B_4C with B.

The results will be discussed.

8848-23, Session 5

Tackling the demands from new x-ray sources types with tailored multilayer optics

Reiner M. Dietsch, Markus Kraemer, Thomas Holz, Danny Weissbach, AXO DRESDEN GmbH (Germany); David L. Windt, Reflective X-Ray Optics LLC (United States)

Multilayer mirrors are used for increasing numbers of X-ray applications. While most multilayers in laboratory instruments are designed for common tube anode materials (Cu, Mo, Rh, Ag) and the respective characteristic fluorescence line energies, the development of new sources (such as liquid metal jet or laser plasmas) or special applications at synchrotrons and free electron lasers (with polarized radiation or photon energies in the range of few hundred eV) leads to a demand for tuned multilayer mirrors for those fields. We will present a number of special multilayers designed, fabricated and tested in state-of-the-art research, for example:

1) Polarization experiments require a grazing incidence angle of ~45°, much larger than the angle of total external reflection or typical multilayer mirror grazing angles. Thus, a multilayer with hundreds of extremely precise layers having thicknesses of only few Angströms is necessary. For synchrotron polarization experiments such mirrors were successfully produced and tested at wavelength.

2) Around the world numerous new X-ray sources in the soft X-ray range (such as free electron lasers or laser pulsed plasma sources) have started operation recently and for many applications monochromatizing optics such as multilayers are needed. Apart from the production, simulation and testing of these optics especially in the soft X-ray range below 100 eV is challenging due to missing optical constants and reliable calibrated sources, respectively. We simulated, manufactured and characterized multilayers in this range successfully using LPP and synchrotron sources at different laboratories. The measurements showed good agreement with theory.

8848-24, Session 6

Fabrication of x-ray gratings by direct-write maskless lithography

Dmitriy L. Voronov, Lawrence Berkeley National Lab. (United States); Steffen Diez, Heidelberg Instruments GmbH (Germany); Paul Lum, Univ. of California, Berkeley (United States); Sergio A. Hidalgo, Tony Warwick, Nikolay A. Artemiev, Howard A. Padmore, Lawrence Berkeley National Lab. (United States)

Fabrication of diffraction grating for x-rays is a very challenging problem due to the exacting requirements of surface quality and groove profile. Traditional fabrication techniques have significant limitations and do not cover all necessary requirements. For example, classical holographic recording is limited in the type of groove patterns that can be produced. This is particularly important in the design of wide aperture high resolution spectrometers, where aberration correction using complex groove patterns is necessary. Traditional interference lithography and ruling methods are also limited in their ability to produce shallow blazed gratings with maximal efficiency. Here we will show how two new technologies are having an impact in this area and potentially will revolutionize grating performance. We are pioneering the use of direct-write mask-less lithography to make grating patterns of arbitrary complexity, together with the use of anisotropic etching of silicon to produce near atomically perfect groove shapes.

In this work we report on the first results from our direct-write mask-less approach, including quality assessment of the patterns using interferometric techniques, as well as new results on shallow blaze angle anisotropically etched silicon grating. This work was supported by the US Department of Energy under contract number DE-AC02-05CH11231.

8848-25, Session 6

Development of dispersive x-ray spectrometers and applications at SACLA

Yuichi Inubushi, RIKEN (Japan); Tetsuo Katayama, Kensuke Tono, Tadashi Togashi, Japan Synchrotron Radiation Research Institute (Japan); Takahiro Sato, Kanade Ogawa, Makina Yabashi, RIKEN (Japan)

For spectroscopic applications with XFEL light, we have developed two types of dispersive x-ray spectrometers for on-axis and emission geometries.

The on-axis spectrometer consists of an elliptical mirror, a flat analyzer crystal and a two-dimensional detector. We measured spikes of XFEL spectrum with resolution of 14 meV and determined the pulse duration with a help of an XFEL simulation. We have also applied this spectrometer to performing the absorption spectroscopy.

For dispersive emission spectroscopy, we propose a new scheme using a Johansson crystal and a two-dimensional detector. This device was successfully tested to measure Cu-Ka lines with XFEL. light.

8848-26, Session 6

Damage characteristics of platinum/carbon multilayers under focused x-ray free-electron laser irradiation

Jangwoo Kim, Osaka Univ. (Japan); Takahisa Koyama, Hirokatsu Yumoto, Japan Synchrotron Radiation Research Institute (Japan); Ayaka Nagahira, Osaka Univ. (Japan); Satoshi Matsuyama, Osaka Univ. (Japan) and Japan Science and Technology Agency (Japan); Yasuhisa Sano, Osaka Univ. X-ray free-electron lasers (XFELs) can now be used to produce intense femtosecond pulses in the hard X-ray region. The use of these X-ray sources in conjunction with analysis methods has unique advantages, and their applications in exploring new frontiers in science may be possible by using focusing optics. Sub-100 nm focusing under the diffraction-limited condition has already been achieved using total reflection mirrors. The use of X-ray mirrors for reducing the focal spot size requires a large grazing incidence angle in order to increase the numerical aperture. A multilayer mirror provides for a sufficiently large grazing incidence angle to accommodate spot size reduction, which cannot be achieved using total reflection mirrors. In this study, we evaluated the irradiation damage caused to platinum/carbon multilayers induced by hard XFELs. Intense X-ray beams cause damage to multilayer structures. In order to evaluate breakdown thresholds of the multilayer, we compared between the X-ray reflectivities of pre-irradiation and post-irradiation of XFELs in the first-order Bragg peak. We used a focusing XFEL beam with a beam size of approximately 1 μm at the photon energy of 10 keV. The pulse energy was controlled with silicon attenuators of various thicknesses placed in front of the focusing mirror. A pulse energy ranging from 0.01 to 100 μJ was applied in this experiment. We confirmed that the actual condition used is sufficiently lower than the breakdown threshold of platinum/carbon multilayers.

Damage threshold investigation using grazing incidence irradiation by hard x-ray free electron laser

Takahisa Koyama, Hirokatsu Yumoto, Kensuke Tono, Japan Synchrotron Radiation Research Institute (Japan); Takahiro Sato, RIKEN (Japan); Tadashi Togashi, Japan Synchrotron Radiation Research Institute (Japan); Yuichi Inubushi, RIKEN (Japan); Tetsuo Katayama, Japan Synchrotron Radiation Research Institute (Japan); Jangwoo Kim, Satoshi Matsuyama, Osaka Univ. (Japan); Hidekazu Mimura, The Univ. of Tokyo (Japan); Makina Yabashi, RIKEN (Japan); Kazuto Yamauchi, Osaka Univ. (Japan); Haruhiko Ohashi, Japan Synchrotron Radiation Research Institute (Japan)

Since the advent of the X-ray free electron laser (XFEL) facilities, intense ultra-shot pulse and fully transverse coherent X-rays have been available even in the hard X-ray region. Such intense X-rays possibly induce damage of optical elements, which can be a serious problem of degradation in beam quality. To investigate damage thresholds of optical elements, we used focusing XFEL beam that has sufficient power density for studying ablation phenomena.

Focusing beams were produced by a pair of elliptical mirrors arranged in Kirkpatrick-Baez geometry at the XFEL facility SACLA (SPring-8 Angstrom Compact free electron LAser) in Japan. The focusing beam size was approximately 1 µm at a photon energy of 10 keV. We designed and installed a test chamber for irradiation experiments, which is equipped precise scan stages for measuring the beam size by a knife edge scanning method, online microscopes, and a rotation stage for grazing incidence irradiation. Single and/or multiple focusing XFEL beams irradiated to test samples under grazing incident condition. The samples were metal coated wafer that used as X-ray mirror optics. The damage thresholds were evaluated by measuring surface morphologies and X-ray reflectivity.

We found that obtained damage thresholds under grazing incidence condition were several times larger than melting dose calculated under the volume considering X-ray penetration depth.

8848-28, Session 6

Process-induced inhomogeneities in higher asymmetry angle x-ray monochromators

Dusan Korytar, Slovak Academy of Sciences (Slovakia); Patrik Vagovic, Tohoku Univ. (Japan); Claudio Ferrari, Consiglio Nazionale delle Ricerche (Italy); Petr Mikulik, Masaryk Univ. (Czech Republic); Peter Siffalovic, Matej Jergel, Karol Vegso, Edmund Dobrocka, Zdenko Zaprazny, Slovak Academy of Sciences (Slovakia)

Performance of asymmetric inline Ge(220)-based V-shaped monochromators has been recently studied both in metrological and imaging applications for photon energies around 8 keV. Due to refraction effect a drop of the transmitted intensity was observed for higher asymmetry angles. Several ways of correcting this effect have been successfully applied. To study output beam inhomogeneities, imaging experiments were performed at ESRF using a Frelon X-ray camera. By tuning the photon energy of synchrotron radiation the incidence angle and thus the asymmetry angle were changed.

Surface undulations due to chemical polish have been shown to negatively influence monochromator performance close to critical angle of 0.6°. Growth striations in graded GeSi and slightly misoriented grains in single Cu crystal (perspective materials for high intensity monochromators) are clearly visible in X-ray topographs, which fact excludes them from imaging applications. Low dislocation density G, though applicable for monochromators, is not recommended for imaging, neither. Diffracted beam inhomogeneities in thermally tuned V-monochromator may worsen beam parameters even when using dislocation-free material.

Pronounced increase of coherence volume by asymmetric X-ray diffraction gives large sensitivity to phase contrast and process induced surface features are observed as wavefield distortions in interference fringes.

Technological processing of Ge surface by chemical and chemomechanical polishing (CMP) was studied by several techniques. It was shown that CMP produces better surface homogeneity than chemical polish. However, CMP is more difficult to be applied in V-channels. For comparison, measurements on surfaces processed by a mechanical single point diamond turning have shown to be a perspective technology.

The structure of chalcogenide glass-like semiconductors As-Se-S and As-Se-Te doped by samarium

Salima Mekhtiyeva, Azerbaijan National Academy of Sciences (Azerbaijan) and Institute of Physics (Azerbaijan); Abosat Isayev, Institute of Physics (Azerbaijan) and Azerbaijan National Academy of Sciences (Azerbaijan); Gulnar Isayeva, Azerbaijan National Academy of Sciences (Azerbaijan) and Institute of Physics (Azerbaijan)

It is known that there is correlation between physical properties and structure in the chalcogenide glass-like semiconductors (CGS). Changing the process of the sample fabrication, the chemical composition and also doping by impurities in the form of charged centers allows modifying the structure of the CGS materials which influence on their electronic and optoelectronic properties.

This work is devoted to study the structure of the materials As-Se-S and As-Se-Te containing an impurity of samarium (0.1; 0.5; 1; 2; 2.5; 5 at%) by application of X-ray diffraction method.

Broad maxima in the diffraction pattern of films with low concentration of samarium (0.5 at%), show their amorphous nature. Parameters of the first sharp diffraction peak (FSDP) are defined by the special program Evaluation.

An occurrence and a form of FSDP on intensity curves of X-ray diffraction connect with the existence of ordering in the scale of the average order. We calculated the scattering vector corresponding to the FSDP position. The value of “quasi-period” of the structure or the density fluctuations of atoms was estimated. Repeatable of the later in some areas of correlation may stipulate the FSDP appearance. The correlation length (the area size in which the periodicity of the atom fluctuation is remained) was also determined.

The CGS materials differ from the corresponding crystals by existence of free volumes being voids with small sizes (nanovoids). The void diameter and the characteristic distance corresponding to the interatomic correlations were determined according to the Elliot void-cluster model. It was shown that the parameters of the As-Se-S and As-Se-Te structures differ significantly each other. It was connected with the size difference and variety of the structural units.

It was shown that influence of impurity of samarium on structural ordering of As-Se-S and As-Se-Te happens at the level of an average order and possesses the difficult character. Low concentrations (up to 0.5 at%) of samarium atoms increases, and high ones reduces the degree of ordering of the indicated materials. Such behavior is explained by the activity of impurity atoms rare earth elements (Sm), the nature of their distribution inside the sample, the manifestation in the form of positive ions Sm+3 and the change in the concentration of charged intrinsic defects (D + and D-).

Using organic slab to obtain x-ray tube spectra for quantitative analysis of x-ray fluorescence analysis

Song Liu, Qinghui Li, Shanghai Institute of Optics and Fine Mechanics (China)

X-ray tube spectra are obtained using Oroglas materials as scatterers. The measured spectra are corrected for detector efficiency and Compton effect. The relative intensities of the elements in alloys are measured and calculated. The consistency of the experimental results and the theoretical values confirmed the validity of the corrected spectra, indicating that the method introduced in this letter is a simple and valid way of obtaining the X-ray tube spectra for quantitative analysis of X-ray fluorescence analysis.

Diffraction grating efficiency calculations using genetic algorithms

Brian W. Yates, Mark Boots, Matthew Schmeiser, Julian Miller, Alan M. Duffy, Canadian Light Source Inc. (Canada)

A web-based graphical user interface (GUI) has been developed to allow soft x-ray diffraction grating efficiencies to be performed in a parallel fashion. The open source web server Apache Tomcat was used for this purpose on a Linux-based computer. The interface was written in the hypertext preprocessor PHP. The diffraction grating efficiencies were modeled using the Fortran computer source code (Gradif) purchased from M. Neviere, which uses a differential method for solution. The GUI essentially serves as a wrapper to generate the required diffraction grating parameter description from the user, which is fed as input to the Gradif code. The GUI manages the set of calculations requested, extracting and displaying through plots the computed diffraction grating efficiencies.

The interface was developed as a web-based application so that it could be used anywhere through a browser within the Canadian Light Source (CLS) community, which is limited only by the licensing of the Gradif source code. This avoids having to distribute source code or installation on a person's individual computer. Support for multi-threaded calculations has been implemented to parallelize the calculations. Two additional desktop computers (Linux-based), each supporting dual quad-core CPU's, were set up to do these parallel calculations, which are separate from the web server. The user interface is open-source.

Support for genetic algorithms was recently added in order to more efficiently search for the global diffraction grating efficiency optimum as a function of parameter space. Genetic algorithms are based on the processes of genetics and evolution.

Multilevel stacked Fresnel zone plate for hard x-rays

Levon A. Haroutunyan, Yerevan State Univ. (Armenia); Karapet G. Trouni, Candle Synchrotron Research Institute (Armenia); Armen V. Kuyumchyan, American NanoScience and Advanced Medical Equipment, Inc. (United States)

An alternative type of multilevel Fresnel zone plate called stacked multilevel FZP, consisting of stacked layers with bi-level zone profiles, by means of numerical simulation was considered. The interlayer gap width and radial displacement of layers at which focusing properties of the system are close to that of corresponding multilevel FZP, aren't significantly differ from those of bi-level stacked FZP's.

As in the case of stacked bi-level FZP, interference fringes formed behind the optical system can be used as a criterion for layers radial alignment. An alternative criterion based on 0-order diffraction power also is applicable.

The angular sensitivity of the device was observed, and it was shown that it still allows good quality imaging of objects larger than the FZP's diameter. As an example the imaging of a grid structure has been simulated.

Considered approach of FZP fabrication allows achieving focusing efficiency sufficiently higher than the theoretical limit of efficiency for bi-level FZP. At that the fabrication of device does not become significantly difficult since the layers still have bi-level profiles. Another advantage of considered scheme is that it decreases the optimal height of layer profiles 1.5 times which leads to sharper focusing.

The Alba ray tracing code: ART

Josep Nicolas, CELLS - ALBA (Spain); Alessandro Barla, Istituto di Struttura della Materia (Italy); Jordi Juanhuix, CELLS - ALBA (Spain)

The Alba ray tracing code (ART) is a suite of Matlab functions and graphical user interfaces for the ray tracing simulation of x-ray beamlines. ART is organized in different layers. The lower level is constituted by a core of functions for source simulation, ray tracing on basic optical elements - including mirrors, capillaries, crystals and gratings - and a set of functions for statistical analysis of the sets of rays. The core functions can be run independently, or be integrated in functional programs such as beamline design optimization scripts. Within our ray tracing code, they constitute the basic functions for the intermediate layer of ART, which consists in functions that combine several optical elements in a single object. A typical case is the monochromator, which combines different optical elements whose positions and orientations are determined by the tuned energy. Finally, the top layer of the suite is the graphical user interface, called Artiface, which allows the user to control the beamline parameters from a simple graphical panel. Its main feature is that the beamline configuration file is a Matlab function itself, in which the user can insert code. This is particularly useful to explore how misalignments or tolerances affect the performance of the beamline, as well as to test combined-motion alignment routines. Other tools are included, such as a program to use measured slope errors, and to generate artificial slope errors starting from power spectral density distributions of real mirrors. ART also includes a grating efficiency package and a power distribution propagation calculator. Other generic characteristics of ART include the accumulation of rays to improve statistics without memory limitations, and providing normalized values of flux in physically meaningful units. The core functions to transform ART into a wave propagation code are currently under development.

Error compensation for the calibration of mechanical mirror benders

Josep Nicolas, CELLS - ALBA (Spain); Juan Campos, Univ. Autònoma de Barcelona (Spain)

The use of linear methods to obtain both the error surface and the instrument error from redundant-independent datasets has been proposed to improve the accuracy of angle measuring scanning devices such as the long trace profilometer (LTP) or the nanometer optical measuring machine (NOM). The required redundant datasets of the surface are obtained by measuring the mirror several times, with a different pitch orientation with respect to the probe beam every time. The method allows obtaining both the slope profile of the surface under test and the linearity error of the measuring instrument.

In this work we propose to extend the method to measurements obtained during the calibration of a mechanical bender. In this case one obtains the required data redundancy from the measurements obtained

at the different bending conditions of the system. For all the bending conditions, the polishing slope error remains invariant, and the only difference between the different measurements is given by the elastic deformation of the substrate, which depends on two parameters only. In addition, such deformation is very reliably modeled by the elastic beam theory, for the most usual ranges of curvature. The proposed method allows determining an error-free measure of the slope error, the curvature and the cubic component of the mirror, as well as the instrument error. The description of the method, as well as simulations and practical works are presented.

Modulation of intensity in defocused beams

Josep Nicolas, Gastón García, CELLS - ALBA (Spain)

Many X-ray techniques require variable size photon beam on the sample or on the detector. The easiest way to achieve variable spot size is to defocus the beam, typically by changing the bending of the focusing mirrors. Nevertheless, defocusing has the problem that the beam profile is heavily modulated by striations caused by the surface error of the focusing optics. To our knowledge, a relationship between these modulations of the beam and the spatial frequency of the surface error that originates them has not been properly established. In this work we show that beam modulation at a given measurement plane has a nonlinear dependence on the slope profile of the mirror, and on the positions of the focal plane and the measurement plane. The modulation is, in addition, convoluted with the stenopeic image of the source, which behaves as a low-pass filter smoothing out high spatial frequency striations. From the derived relationships it follows that the relative contributions to beam striations of slope error lower and higher spatial frequencies vary depending on how far away the measurement plane is from the focal one. Finally, we explore the relationship between the amplitude of the striations and the power spectral density of the slope errors.

Optimization of the soft x-ray transmission microscopy beamline at the ALBA light source

Andrea Sorrentino, Eva Pereiro, Ricardo Valcárcel, Salvador Ferrer, Josep Nicolas, CELLS - ALBA (Spain)

Mistral is the soft X-ray full field microscopy beamline at the ALBA light source. The beamline is fed by a bending magnet, and it is designed to have large source acceptance and to provide constant angular magnification at the exit slit for photon energies between 270 and 2600 eV. The monochromator is a variation of the Petersen plane grating monochromator in which a variable line spacing grating (VLS) is used to maintain the focus fixed for all energies at the exit slit plane, as well as to cancel higher order aberrations. In order to obtain the desired acceptance and spectral resolution, very large optical surfaces, up to 1.2 m long, and very short distances between them were required. A consequence of this is that the spectral resolution of the beamline is very sensitive to misalignments and to manufacturing tolerances of its optical elements such as the radii of curvature of the optical surfaces, and especially the VLS parameters of the gratings. Another constraint is given by the requirement of the x-ray microscope to have the beam focused both vertically and horizontally onto the exit slit.

In this work we present the alignment strategy we followed during the commissioning, which we used to compensate for the tolerance errors of the optical elements in order to achieve the required spectral resolution, and to preserve both vertical and horizontal focus at the same plane. We also give details on how mechanical stress torsion was diagnosed on one of the gratings, and on how the energy calibration of the monochromator was performed. Finally we report on how the beamline is capable of compensating drifts of the source position preserving the beam conditions at the exit slit and on the microscope.

Development of an objective flat-field spectrograph for electron microscopic soft x-ray emission spectrometry in 50-4000 eV

Takashi Imazono, Masato Koike, Tetsuya Kawachi, Noboru Hasegawa, Japan Atomic Energy Agency (Japan); Masaru Koeda, Tetsuya Nagano, Hiroyuki Sasai, Yuki Oue, Zeno Yonezawa, Satoshi Kuramoto, Shimadzu Corp. (Japan); Masami Terauchi, Tohoku Univ. (Japan); Hideyuki Takahashi, Nobuo Handa, Takanori Murano, JEOL Ltd. (Japan)

We have developed an objective soft x-ray flat-field spectrograph to be able to attach to electron microscopes (EMs). This spectrograph has two attractive features. One is that it is designed to cover a wide energy range of 50-4000 eV by using four varied-line-spacing holographic gratings (VLSHGs) optimized for 50-200 eV, 155-350 eV, 300-2200 eV, and 2000-4000 eV. The gratings dedicated for the respective energy ranges can be accommodated in the single spectrograph. This advantage comes from that the positions of the source points and image planes are assumed as the common parameters in the design of the all gratings. Therefore, it allows us to easily change the energy range by only choosing an appropriate grating and its position. The other is the application of a newly invented W/B4C multilayer coating. It has been adopted to the grating for the 2000-4000 eV range to overcome the considerable decrease of the diffraction efficiency in the energy range above ~2 keV. The novel coating allows us to enhance the diffraction efficiency up to a practical level, at least over 1%, at a constant incidence angle in the whole energy range. The multilayer structure is based on the same concept as hard x-ray supermirrors, but extremely simplified.

The details of the optical design of the spectrograph accommodating four VLSHGs, the conceptual design of the multilayer structure, the diffraction efficiencies and resolving power obtained experimentally as well as some emission spectra measured by the spectrographs attached to EMs will be presented in the conference.

Investigation of high-thermal-contact-conductance in low-contact pressure for high-heat-load optical elements of synchrotron radiation

Tomoyuki Takeuchi, Masayuki Tanaka, Haruhiko Ohashi, Shunji Goto, Japan Synchrotron Radiation Research Institute (Japan)

Many high-heat-load components are cooled by water or liquid nitrogen under indirect configuration for synchrotron radiation beamlines. Thermal-contact-conductance (TCC) is crucial property for the design of indirect cooling components. TCC depends on contact material, contact pressure, and surface condition. Low contact pressure is needed to reduce strain on an optical element, resulting in small value of TCC. We are seeking a condition with interstitial material of a high TCC in low contact pressure region.

The TCC measurements were performed between copper rods with interstitial material under water cooling, in vacuum, and under low contact pressure of 0.1-1.0 MPa. Large variance of TCC was observed for a bare surface of copper due to surface oxidization. Although, nickel-plated copper showed stable TCC value, it was smaller than that of bare copper. We will show TCC results that will be applied for indirect-cooling crystal monochromators and mirrors.

Engineering optical constants for broadband single layer anti-reflection coatings

Sebastiaan P. Huber, Robbert W. van de Kruijs, Andrey E. Yakshin, Erwin Zoethout, FOM Institute DIFFER (Netherlands); Fred Bijkerk, FOM Institute DIFFER (Netherlands) and MESA+ Institute for Nanotechnology (Netherlands)

Single layer anti-reflection coatings are often assumed to be limited to minimize reflection in a narrow bandwidth around a specific wavelength. In this paper we show that there are in principle no fundamental restrictions for single layer anti-reflection coatings to exhibit broadband suppression. We present theoretically derived design rules for an anti-reflection coating for the spectral range of 100N400 nm, applied here on top of a molybdenum-silicon multilayer mirror as commonly used in extreme-ultraviolet lithography. The design rules for optimal suppression are found to be strongly dependent on the thickness and optical constants of the coating. As a proof of principle, thin films were deposited that exhibit optical constants close to the design rules for suppression around 300 nm.

In order to minimize EUV absorption losses, we used silicon based compounds which are relatively transparent to EUV radiation. SixCyNz layers were deposited by electron beam co-deposition of silicon and carbon, with N+ ion implantation during growth.

The thin films were analyzed with variable angle spectroscopic ellipsometry to characterize the optical constants. The results show that the optical constants of SixCyNz films can be engineered to match those specified by the design rules. This work illustrates that a single layer anti-reflection coating can be used to achieve broadband suppression using appropriately tailored optical constants.

Recent performance of the APS optical slope measuring system

Jun Qian, Lahsen Assoufid, Joseph Sullivan, Argonne National Lab. (United States)

Abstract: An optical slope measuring system (OSMS) at the Advanced Photon Source of the Argonne National Laboratory was first reported in 2012 [1]. This system is equipped with a precision autocollimator and a very accurate mirror-based pentaprism on a scanning stage and kept in an environment-controlled enclosure. This system has the capability for measuring precision X-ray optics with sub-microradian rms slope errors, which has been verified via a number of measurements with high quality mirrors. In this paper, we gave recent performance of the system, including stability, repeatability and reliability, after more precise optical alignment and better temperature control.

Double-stage soft x-ray laser pumped by multiple pulses applied in grazing incidence *(Invited Paper)*

Thomas Kuehl, Gesellschaft für Schwerionenforschung GmbH (Germany) and Johannes Gutenberg Univ. (Germany) and Helmholtz Institute Jena (Germany); Boris Ecker, Gesellschaft für Schwerionenforschung GmbH (Germany) and Johannes Gutenberg Univ. (Germany); Bastian Aurand, Lund Laser Ctr. (Sweden); Paul Neumayer, Extreme Matter Institute (Germany); Bernhard Zielbauer, Gesellschaft für Schwerionenforschung GmbH (Germany); Huanyu Zhao, Quanyu Jin, Institute of Modern Physics (China); Eduardo Oliva, Thi Thy Thuy Le, Philippe Zeitoun, Li Lu, Ecole Nationale Supérieure de Techniques Avancées (France); Kevin Cassou, Sameh Daboussi, Olivier A. Guilbaud, Sophie Kazamias, David Ros, Univ. Paris-Sud 11 (France)

X-ray laser (XRL) research activities at PHELIX / GSI are dedicated to establish a reliable, fully characterized nickel-like plasma - XRL source for application, in particular for performing spectroscopy experiments on highly charged heavy-ions stored in the Experimental Storage Ring (ESR) of the GSI accelerator structure and later on at the HESR High-Energy Storage Ring at FAIR[1]. Plasma XRL sources will allow the direct excitation of 1S – 2P1/2 transitions of a large number of Lithium like ions, including also radioactive isotopes, for precision studies of high-field physics.

We report here on results of laser seeding in a two-stage plasma XRL scheme. The two targets were pumped using the double-pulse grazing incidence pumping technique, which includes travelling wave excitation for both the seed- and the amplifier-target[2]. In addition, another pumping scheme relying on a third pulse has been studied. Seeded x-ray laser operation has been demonstrated in both schemes, resulting in x-ray laser pulses with a divergence of 2 mrad x 2 mrad. The peak brilliance of the amplified x-ray laser of 4x1023 photons /s /mm^2 /mrad^2 in 5x10-5 relative bandwidth was more than two orders of magnitude larger compared to the original seed pulses. The presented experimental concept provides an alternative to the currently more common approach to use high-order harmonic pulses as a seed source, with a perspective [3] leading towards even much higher brilliance.

Sub-10-nm Ni-like soft-x-ray lasers

Juerg E. Balmer, Fei Jia, Felix Staub, Univ. Bern (Switzerland)

We report on recent progress achieved in x-ray laser research at the Institute of Applied Physics of the University of Bern. Using the existing 10-TW Nd:glass CPA (chirped-pulse amplification) laser system in the grazing-incidence pumping (GRIP) scheme, saturated or near-saturated soft-x-ray lasing has been obtained on the 4d - 4p, J = 0-1 lines of barium (Ba, Z = 56), lanthanum (La, Z = 57), and samarium (Sm, Z = 62) at wavelengths down to 7.36 nm, with weak lasing observed at 6.85 nm. This was achieved with main pulse energies of ~10 J and a pulse duration of 1.5 ps. Crucial to these results was the introduction of a second, relatively intense (16%) prepulse ~30 ps before the main pulse, in addition to the 8% prepulse incident on target several nanoseconds before the main pulse. A small-signal gain coefficient of ~30 cm^-1 and a gain-length product of ~16 at saturation have been measured in the case of the 9.2-nm Ba laser. Crucial to these results was the introduction of a second, relatively intense (~15%) prepulse less than ~50 ps before the main pulse, in addition to the 2.8% prepulse that irradiated the target ~3 ns earlier. Traveling-wave excitation was used throughout.

8849-3, Session 1

Development and applications of X-ray lasers at PALS Centre

Michaela Kozlová, Institute of Physics of the ASCR, v.v.i. (Czech Republic)

The results of development and aplications of the X-ray sources at PALS Center will be presented. Currently the iodine system and the Ti:Sapphire system are operating at the PALS Center as driving lasers for generation of secondary sources. The iodine system with net energy of 1kJ is used for QSS lasing schemas. The most robust and most energetic QSS schema with this driver is Ne-like Zn X-ray laser, which is working here as standard user beamline for diverse applications. The second system with high rep rate is Ti: Sapphire laser chain with peak power 20TW. This laser system is used for generation HHG and GRIP schema.

8849-30, Session 1

Maxwell-Bloch modelisation of the amplification of a double seed pulse with variable delay

Philippe Zeitoun, Ecole Nationale Supérieure de Techniques Avancées (France); Thi Thu Thuy Le, Eduardo Oliva, Univ. Paris-Sud 11 (France); Li Lu, Ecole Nationale Supérieure de Techniques Avancées (France); David Ros, Univ. Paris-Sud 11 (France); Jorge J. Rocca, Colorado State Univ. (United States)

Ultra-fast and ultra-intense soft x-ray sources, like high harmonic generation and free-electron lasers, opened new avenues for applications in solid-state physics, biology, plasma physics etc. Most recent applications required x-ray pulses with high degree of spatial coherence, good wave front and duration below 100 fs. Plasma-based soft x-ray lasers have the potentiality to complement soft x-ray free-electron lasers by delivering ultra-intense and energetic beams to users. In this perspective, the most advanced concept is based on the transposition of Chirped Pulse Amplification in X-rays [Oliva et al, Nat. Phot, 2012]. This technics relies on the fast recovery of gain after amplification of ultra-fast seed. As a first step, we numerically study the amplification of two seed pulses with variable delay between them. Such double pulse has interest for pump-probe experiments. Using 1D time-dependant Maxwell-Bloch model that includes amplification of spontaneous emission, we modelled the temporal variation of the intensity of the two seed pulses for various conditions. We consider neonlike zinc plasma amplifying high harmonics at 21.2 nm. We observed the interaction of the two pulses for delays below 2 ps.

8849-5, Session 2

Bright ultrahigh harmonic generation in the keV x-ray regime using tabletop mid-IR lasers *(Invited Paper)*

Tenio Popmintchev, Ming-Chang Chen, Dimitar Popmintchev, JILA (United States); Skirmantas Alisauskas, Giedrius Andriukaitis, Audrius Pugzlys, Andrius Baltuska, Technische Univ. Wien (Austria); Bonggu Shim, Alexander L. Gaeta, Cornell Univ. (United States); Carlos Hernandez-Garcia, Luis Plaja, Univ. de Salamanca (Spain); Margaret M. Murnane, Henry C. Kapteyn, JILA (United States)

We demonstrate the most extreme phase-matched nonlinear upconversion process to date, coherently combining over 5001 mid-infrared femtosecond laser photons to generate bright ultra high-order harmonics spanning the electromagnetic spectrum from the UV to above 1.6 keV. In a remarkably favorable convergence of nonlinear optical phenomena, the multi-atmosphere gas pressures that enable efficient X-ray generation also self-confines the laser beam, further enhancing the X-ray yield. This realizes the first coherent version of the Roentgen X-ray tube in the soft X-ray region of the spectrum on a tabletop. We also present a generalized picture of phase matching of high harmonic generation (HHG) that combines microscopic quantum physics with macroscopic extreme nonlinear optics. Counterintuitively, to generate the brightest harmonics, the order of the nonlinearity must dramatically increase from ~11 in the VUV, to >101 in the EUV, to >5001 in the keV X-ray region. The phase-matched emission evolves from a single harmonic in the VUV, to a broad X-ray supercontinuum spanning thousands of harmonics in the soft X-ray region that in theory can support single cycle X-ray pulses as short as 2.5 attoseconds. Finally, when longer-wavelength driving lasers are used, the phase-matched ultrahigh harmonic generation is scalable to even sub-attosecond (zeptosecond) time scales. These unique ultrafast HHG X-rays of full spatial and temporal coherence can capture the fastest motions of charges, spins, phonons and photons in molecules and materials in real time, as well as enables imaging near the wavelength limit.

8849-6, Session 2

Generation of a beat-wave pulse train for quasi-phase-matched high-harmonic generation

Chi-Hsiang Yang, Shih-Chi Kao, National Central Univ. (Taiwan); Jyhpyng Wang, Institute of Atomic and Molecular Sciences (Taiwan); Hsu-Hsin Chu, National Central Univ. (Taiwan)

For efficient high-harmonic generation at short wavelengths, a beat-wave pulse train is generated from a two-color Ti:sapphire amplifier system. By using such pulse train to collide with the main driving pulse in the interacting media, quasi-phase matching can be achieved. The 66-fs pulse separation matches to a quasi-phase-matching zone length of 4.9 µm, which corresponds to a dephasing length for 3-nm harmonic generation under 1.0x10^18 cm^N3 plasma density.

The two-color amplifier system is a branch of the 100-TW Ti:sapphire laser system we built at National Central University. We split a 1-mJ pulse from the main amplifier chain as its seed pulse. It is compressed and focused into a krypton-filled tube for supercontinuum generation. The supercontinuum spectrum is shaped by an acousto-optic programmable dispersive filter into a twin-peak structure, and then seed into a two-stage Ti:sapphire amplifier chain. The final output spectrum has equal intensity and bandwidth of its 877-nm peak and 907-nm peak.

The two-color output wave is compressed by a grating compressor. As a result of that the two frequency components are spatially separated on the roof mirror, we use individual roof mirror for each component to adjust their relative delay. For demonstration, we compress the two-color wave to 600-fs duration. A train of about 10 pulses with 66-fs separation is observed by general cross-correlation measurement. The total energy of the two-color beat wave is 100 mJ. It can support an envelope duration longer than 100 ps, corresponds to a number of quasi-phase-matching zones more than 1000.

8849-7, Session 2

Transmission imaging of sodium in the vacuum ultra-violet spectral range: new application for an intense VUV source

Hiroyuki Daido, Japan Atomic Energy Agency (Japan)

Although the metallic sodium was proposed as a transparent material in the vacuum ultra-violet (VUV) spectral range in 1930s (1) and in 1960s, (2) the extinction coefficient was measured with use of only a sub-?m thick sodium foil on a substrate. However no clear transmission has been demonstrated. In this paper we describe the direct measurement of actual transmittance of a sodium sample with thickness of a 1~3 mm instead of sub-m layers in a spectral range longer than 115 nm which corresponds to the shortest transmission wavelength of magnesium fluoride (MgF2) windows, resulting in, for example, 30 % transmittance of a 3 mm thick solid sodium sample including MgF2 windows and the reflection losses at the wavelength of 120 nm with very weak temperature dependence up to 120 degrees centigrade which is beyond the melting point of 97 degrees. Based on the transmission measurements, we set up a simple transmission imaging configuration with a 2-mm thick sodium sample, resulting in clear images composed of 100 m diameter tungsten bars recorded on a two dimensional Charge Coupled Device detector coupled with a phosphor plate and optical fibers. The result also opens a way to construct an optical imaging device for objects inside or through a solid or a liquid sodium medium with thickness of several cm. We believe that the present results show a real demonstration of the transparent sodium in the VUV spectral range proposed firstly by Wood. According to the present extinction coefficient coupled with layer to layer reflectivity, we can make a continuous real time transmission imaging experiment for a few-cm thick liquid sodium sample if we use proper optical setup including an intense VUV source. Such an experiment opens up a way to design and construction of a visualization device for transmitted images through or inside a sodium medium.

Koga, Yuji Fukuda, Masaharu Nishikino, Takashi Imazono, Noboru Hasegawa, Tetsuya Kawachi, Hiroyuki Daido, Japan Atomic Energy Agency (Japan); Yoshiaki Kato, The Graduate School for the Creation of New Photonics Industries

(Japan); Paul R. Bolton, Sergei Bulanov, Kiminori Kondo, Japan Atomic Energy Agency (Japan)

We have recently discovered a new regime of high-order harmonic generation [Phys. Rev. Lett. 108, 135004 (2012)] by multi-TW femtosecond lasers focused to gas jet targets, where comb-like spectra with hundreds of harmonic orders, reaching the photon energy of 500 eV, including the 'water window' spectral range, were generated by either linearly or circularly polarized pulses. In this presentation we describe the results of new experiments with the J-KAREN laser in KPSI, JAEA, namely (i) the discovery of a strong off-axis XUV high-order harmonics emission, (ii) the detailed study of the high-resolution on-axis harmonics spectra, and (iii) the measurements of the harmonics source size and angular divergence which allow more accurate estimate of the peak spectral brightness, much more favorable compared to the previous conservative estimates.

8849-9, Session 3

The optical design of the soft x-ray self seeding at LCLS

Daniele Cocco, SLAC National Accelerator Lab. (United States); Rafael Abela, Paul Scherrer Institut (Switzerland); John W. Amann, SLAC National Accelerator Lab. (United States); Ken P. Chow, Paul J. Emma, Lawrence Berkeley National Lab. (United States); Yiping Feng, Georg L. Gassner, Jerome B. Hastings, Philip A. Heimann, Zhirong Huang, Nicholas M. Kelez, Henrik Loos, Paul A. Montanez, Daniel S. Morton, Heinz-Dieter Nuhn, Daniel F. Ratner, SLAC National Accelerator Lab. (United States); Larry N. Rodes, Lawrence Berkeley National Lab. (United States); Uwe Flechsig, Paul Scherrer Institut (Switzerland); James J. Welch, Juhao Wu, SLAC National Accelerator Lab. (United States)

After the successful demonstration of the hard X-ray self-seeding at LCLS (Nature Photonic 6(10) 693 (2012)), an effort to build a system for working in the soft X-ray region is ongoing. The idea for self-seeding in the soft X-ray region by using a grating monochromator was first proposed by Feldhaus et. Al (Opt. Comm., 140, 341 (1997)). The concept places a grating monochromator in middle of the undulators and selects a narrow bandwidth "seed" from the SASE beam produced by the upstream section of undulators, which is then amplified to saturation in the downstream section of the undulators. The seeded FEL beam will have a narrower bandwidth approaching the transform limit. The challenge is to accommodate a monochromator and refocusing system as well as the electron beam magnetic chicane into a very limited space. The LCLS prototype replaces only a single undulator section of ~ 4 m. A general description of the Soft X-ray Self seeding project and the expected FEL performances are described elsewhere (proceeding of the FEL 2012 conference). Here we present the detailed optical design solution, consisting of a fixed incidence angle toroidal blazed grating with variable groove density, a rotating plane mirror (the only required motion for tuning the energy) to redirect the selected monochromatic beam onto an exit slit, and two more mirrors, one sphere and one flat, to focus and overlap the 'seed' onto the electron beam in the downstream undulators. The performance, ablation issues, metrology and alignment will also be discussed.

8849-11, Session 3

Imaging of fine structures of cellular organelles in hydrated biological cells by a soft x-ray microscope combined with a fluorescence microscope

Masataka Kado, Maki Kishimoto, Japan Atomic Energy Agency (Japan); Satoshi Tamotsu, Keiko Yasuda, Masato Aoyama, Nara Women's Univ. (Japan); Kunio Shinohara, Japan Atomic Energy Agency (Japan)

Soft x-ray microscope is very powerful tool to observe cellular organelles of hydrated biological cells and many works have demonstrated imaging of inner structures of the cells. However the inner structures are very complicated and it is difficult to identify the organelles from the image obtained with the soft x-ray microscope by itself. We have proposed to use a fluorescence microscope to identify the cellular organelles in the images obtained with the soft x-ray microscope observing the same cells with both microscopes. We have developed a special specimen holder designed to be optimized for the application to both microscopes so that the cells in the specimen holder can be observed by the both microscopes. The cells were cultivated directly onto the PMMA photo resists and stained in advance with several fluorescent dyes such as Mito-tracker, Phalloidin, and DAPI to image mitochondria, actin filament, and chromatin, respectively. Right after taking many fluorescence images of cellular organelles the cells were exposed to the flash soft x rays radiated from thin foiled gold plasmas produced by a 20 J, 600 ps pulsed laser. The obtained soft x-ray images and fluorescence images of the cells were directly compared and each of the cellular organelles such as mitochondria, actin filaments, and chromosomes in the soft x-ray images was clearly identified. Since the soft x-ray microscope has higher spatial resolution than that of the fluorescence microscope, fine structures of the cellular organelles in the hydrated biological cells were observed for the first time.

8849-12, Session 3

Corrosion-resistant Mg/SiC multilayer coatings for EUV laser sources in the 25-80 nm wavelength region *(Invited Paper)*

Regina Soufli, Monica Fernandez-Perea, Jeffrey C. Robinson, Sherry L. Baker, Jennifer Alameda, Christopher C. Walton, Lawrence Livermore National Lab. (United States); Luis Rodríguez-De Marcos, José A. Méndez, Juan I. Larruquert, Consejo Superior de Investigaciones Científicas (Spain); Eric M. Gullikson, Lawrence Berkeley National Lab. (United States)

The 25-80 nm wavelength region is part of the operational range of extreme ultraviolet (EUV) free-electron laser and tabletop laser sources, with applications in plasma physics, materials characterization, photochemistry, nano-patterning, and microscopy. These applications require multilayer-coated optics as collector and imaging elements. Mg/SiC possesses a unique combination of favorable reflective properties, unmatched by any other candidate multilayer coating in the 25-80 nm region: consistently high reflectance, near-zero film stress, good spectral selectivity and thermal stability up to 350? C. However, Mg/SiC suffers from Mg-related corrosion, an insidious and unpredictable problem which completely degrades reflectance and has prevented Mg/SiC from being used in applications that require long lifetime stability. We have elucidated the origins and mechanisms of corrosion propagation within Mg/SiC multilayers. Based on our findings, we have demonstrated an efficient and simple-to-implement corrosion barrier for Mg/SiC multilayers. The barrier consists of nanometer-scale Mg and Al layers that intermix spontaneously to form a partially amorphous Al-Mg layer and is shown to dramatically reduce corrosion while maintaining the unique combination of favorable Mg/SiC reflective properties. We have demonstrated experimentally a variety of concepts for corrosion-resistant Mg/SiC multilayers which achieve high reflectance in up to three narrow bands simultaneously, in the 25-80 nm region. We have also measured and modeled the in-band and out-of-band response of these multilayers in the 11-200 nm wavelength range.

8849-27, Session 3

Femtosecond x-ray pulse temporal characterization in free-electron lasers *(Invited Paper)*

Christopher Behrens, Deutsches Elektronen-Synchrotron (Germany) and SLAC National Accelerator Lab. (United States)

The ability to temporally characterize x-ray pulses from free-electron lasers (FELs) will underpin their exploitation in experiments ranging from single-molecule imaging to extreme timescale x-ray science. This issue is especially acute when confronted with the characteristics of current generation x-ray FELs, as most parameters fluctuate strongly from pulse to pulse. Here, we review recent advances in the temporal characterization of x-ray pulses at FELs, with the emphasis on techniques of femtosecond resolution and single-shot capability. Measurements in the soft and hard x-ray regime of current generation x-ray FELs will be discussed.

8849-13, Session 4

Observation of the nano-scale surface dynamics of femtosecond laser ablation by time-resolved soft x-ray imaging technique *(Invited Paper)*

Masaharu Nishikino, Noboru Hasegawa, Japan Atomic Energy Agency (Japan); Takuro Tomita, Univ. of Tokushima (Japan); Yasuo Minami, Ryota Takei, Motoyoshi Baba, The Univ. of Tokyo (Japan); Takashi Eyama, Takayoshi Syodai, Univ. of Tokushima (Japan); Tetsuya Kawachi, Mitsuru Yamagiwa, Japan Atomic Energy Agency (Japan); Tohru Suemoto, The Univ. of Tokyo (Japan)

The dynamical processes of the femosecond laser-induced surface modifications come to attract much attention for the micro processing. However, it is difficult to observe the femtosecond laser ablation dynamics, because of non-repetitive, irreversible and rapidly changing phenomena in a small characteristic size. Thus, the details of femtosecond laser ablation process have not been understood well. The measurement technique with the sufficient temporal and spatial resolution is necessary for the better understanding of the femtosecond laser ablation. In this study, we have developed the pump and probe interferometer and reflective imaging technique of the metal surfaces during the femtosecond laser ablation by using the laser-driven soft x-ray laser at the wavelength of 13.9 nm. The pumping laser used for the ablation was a Ti: Sapphire laser pulse with the duration of 80 fs pulse at a central wavelength of 795 nm, and had a gaussian spatial profile. By using the x-ray imaging technique, the time resolved image of nano-scaled ablation dynamics of the platinum was obtained. At the timing of 36 ps after the femtosecond laser irradiation, the maximum surface expansion and expansion speed were measured to be about 60 nm and 1700 m/s, respectively. We have compared the plasma expansion measured by the x-ray interferometer with the ablated hole measured by the atomic force microscopy, and discussed the fluence dependence of the femtosecond laser ablation. These results lead to better understanding of the initial process of the laser ablation dynamics.

8849-14, Session 4

Nano-meter scale modifications on material surfaces induced by soft x-ray laser pulse irradiations

Masahiko Ishino, Anatoly Y. Faenov, Momoko Tanaka, Japan Atomic Energy Agency (Japan); Satoshi Tamotsu, Nara Women's Univ. (Japan); Tatiana A. Pikuz, Noboru Hasegawa, Masaharu Nishikino, Japan Atomic Energy Agency (Japan); Nail Inogamov, Igor Skobelev, Vladimir E. Fortov, Genri Norman, Sergey Starikov, Vladimir Stegailov, Russian Academy of Science (Russian Federation); Takeshi Kaihori, Tetsuya Kawachi, Mitsuru Yamagiwa, Japan Atomic Energy Agency (Japan)

To study the interactions between soft x-ray laser (SXRL) beam and material surfaces, we irradiated the SXRL beam pulses having a wavelength of 13 nm and duration of 7 ps to aluminum (Al), gold (Au), copper (Cu), and silicon (Si) surfaces. Following irradiation, the surfaces were observed using a scanning electron microscope and an atomic force microscope. With single pulse irradiation, the formation of conical structures was observed on the Al surface, and ripple-like structures were formed on the Au and Cu surfaces. The conical structures on Al surface were destroyed under the multiple SXRL pulse exposures, but it was confirmed that the development of modified structures was observed after multiple pulse exposures on the Au and Cu surfaces. On the Si surface, deep holes that seemed to be melted structures induced by the accumulation of multiple pulses of irradiations were found. Therefore, it was concluded that SXRL beam irradiation of various material surfaces causes different types of surface modifications, and the changes in the surface behaviors are attributed to the differences in the elemental properties, such as the melting points and the attenuation length of x-ray photons.

8849-15, Session 4

Nanoscale 3D chemical contrast imaging by soft x-ray laser ablation mass spectrometry

Ilya Kuznetsov, Gerald Gasper, Cornelius Oster, Colorado State Univ. (United States); David Carlton, Weilun Chao, Erik H. Anderson, Lawrence Berkeley National Lab. (United States); Elliot R. Bernstein, Dean C. Crick, Jorge J. Rocca, Carmen S. Menoni, Colorado State Univ. (United States)

Mass Spectrometry Imaging (MSI) has played an important role in the direct examination of the chemical composition of complex inorganic and organic samples. Typically a visible/ultraviolet laser is used to ablate the sample and create ions that when detected allow to identify molecular composition. We have pioneered the use of soft x-ray (SXR) lasers in the implementation of a novel laser ablation mass spectrometry (XLAMS) nanoprobe that can probe chemical composition from sample regions of a few atto-liters volume and with high sensitivity. The concept exploits: i) high focusability, ii) low penetration depth and iii) high photo-ionization efficiency of the 46.9 nm wavelength SXR laser light. In this work we demonstrate the capabilities of XLAMS to realize 2D and 3D chemical contrast imaging with ~140 nm lateral and ~50 nm depth resolution and high sensitivity. The high lateral and depth resolution and high sensitivity of XLAMS imaging method offer great potential for composition imaging of nanofilms and nanostructures and imaging the chemical distribution of dopants and trace elements.

8849-16, Session 4

Prospects of ultrafast x-ray absorption investigations using laboratory based sources

Holger Stiel, Matthias Schnuerer, Max-Born-Institut für Nichtlineare Optik und Kurzzeitspektroskopie (Germany); Herbert Legall, Wolfgang Malzer, Lars Anklamm, Technische Univ. Berlin (Germany); Karol A. Janulewicz, Mazhar Iqbal, Gwangju Institute of Science and Technology (Korea, Republic of); Peter V. Nickles, World Class Univ. (Korea, Republic of)

Ultrafast X-ray absorption spectroscopy (UXAS) offers the opportunity to investigate function-structure relationships of complex organic molecules

or biological functional subunits without the need of crystallization. Of special interest from the viewpoint of structural biology are the spectral region of the so called water window (280.. 500 eV) and the region of K-edges of transition metals between 4 and 10 keV. It should be noted that the structural information gained from UXAS is complementary to the related data derived from time-resolved diffraction measurements. Regardless of successful application of time-resolved diffraction techniques to investigations of crystal dynamics using synchrotron and laboratory based sources [1] there are only very few examples for application of UXAS to revealing the structural dynamics in biomolecular systems. This is mainly caused by the lack of broadband ultrafast sources as well as of appropriate X-ray optics adopted to these sources. Due to the long-data-recording time in UXAS experiments the sample integrity is mainly determined by the average power of the pump pulse. Using a fixed energy of the pump pulse the latter one is determined by the repetition rate of the pump laser. In this paper we discuss the prospects of UXAS comparing fs laser plasma sources with different repetition rates together with tailor-made optics [2] based on highly annealed pyrolytic graphite (HAPG).

Experimental set-up for high-resolution x-ray spectroscopy of solid and liquid samples

Zhong Yin, Ivan Rajkovic, Simone Techert, Mirko Scholz, Dirk Raiser, Max-Planck-Institut für Biophysikalische Chemie (Germany)

Here we present an experimental setup for high resolution X-ray spectroscopy of solid and liquid samples in the soft X-ray region. The setup consists of a multipurpose chamber, a high resolution grating spectrometer in grazing incident, a photodiode and a sample holder for both solid and liquid targets. The concaved curvaured grating has 2400 grooves/mm and a curvaure radius of 57860 mm covering a wide rage of energies, from soft X-rays up to a few keVs. The photodiode is placed wiht an angle of 90° in respect to the target and records the absorption in fluoresence yield. An advantage of the experimental setup is the target holder, which can povide solid or liquid samples. The liquid jet delivery system is capable of providing liquid jets with diameter from 5-100 micrometers. The liquid jet provides always fresh samples and therefore radiation damage can be prevented. The liquid environment is especially important for experiments with biological and chemical purpose. The samples are collected by a cooling finger immersed in liquid nitrogen. This setup is also be used for ultrafast pump/probe experiments.

8849-18, Session 5

Multi-tens of GW peak power plasma-based soft X-ray laser *(Invited Paper)*

Eduardo Oliva, Univ. Paris-Sud 11 (France); Marta Fajardo, Univ. Técnica de Lisboa (Portugal); Lu Li, Ecole Nationale Supérieure de Techniques Avancées (France); Thi Thu Thuy Le, David Ros, Univ. Paris-Sud 11 (France); Stéphane Sebban, Ecole Nationale Supérieure de Techniques Avancées (France); Pedro Velarde, Univ. Politécnica de Madrid (Spain); Philippe Zeitoun, Ecole Nationale Supérieure de Techniques Avancées (France)

Ultra-intense X-ray sources have opened new avenues by creating new states of matter or probing and imaging living or inert matter. Free-electron lasers have a strong leadership by delivering pulses combining femtosecond duration and 10's of microJoules to milliJoule energy. However, these sources remain highly expensive limiting their number to a few worldwide. In parallel, laser-pumped soft X-ray lasers hold outstanding promises having demonstrated the most energetic monochromatic soft x-ray pulse and being intrinsically fully synchronized with any secondary source of the pump laser. Since the first successful demonstration of amplification of a high harmonic pulse in a plasma from gas in 2003 [1] and from solid in 2008 [2], we have developed an extensive numerical study.

2D hydrodynamic simulations showed that optimized Transient Collisional Excitation plasma amplifiers, may store up to 0.4 mJ in the population inversion. If carefully seeded, pulses of 80 fs and 20 μJ might be generated with table-top lasers (10J).

As the energy extracted is far from the milliJoule requirements of most exciting applications, we studied the seminal experiment of Ditmire et al [3] who seeded a plasma emitting milliJoules in the form of Amplified Spontaneous Emission (ASE).We retrieved and explained for the first time the experimental result (ASE 1,000 times stronger than amplified seed). We thus proposed and fully modeled the transposition of the so-called Chirped Pulse Amplification (CPA) in the soft X-ray range, showing that 6 mJ, 200 fs, fully coherent soft X-ray pulse is accessible with compact pump lasers [4].

8849-19, Session 5

Measurement of the gain dynamics in injection-seeded soft x-ray lasers

Yong Wang, Shoujun Wang, Colorado State Univ. (United States); Lu Li, Eduardo Oliva, Ecole Nationale Supérieure de Techniques Avancées (France); Mark Berrill, Oak Ridge National Lab. (United States); Liang Yin, Jaroslav Nejdl, Colorado State Univ. (United States); Thi Thu Thuy Le, Ecole Nationale Supérieure de Techniques Avancées (France); Brad M. Luther, Colorado State Univ. (United States); David Ros, Ecole Nationale Supérieure de Techniques Avancées (France); James Dunn, Lawrence Livermore National Lab. (United States); Philippe Zeitoun, Ecole Nationale Supérieure de Techniques Avancées (France); Jorge J. Rocca, Colorado State Univ. (United States)

The generation of intense pulses of coherent soft x-ray radiation is of great interest for applications in numerous fields. Injection-seed plasma amplifiers have been demonstrated to produce intense fully phase coherent soft x-ray pulses. Herein we report the measurement of the gain dynamics in a soft x-ray plasma amplifier seeded by high harmonic pulses. A sequence of two time-delayed spatially-overlapping high harmonic pulses was injected into a λ=18.9 nm Ni-like Mo plasma amplifier to measure the regeneration of the population inversion that follows the gain depletion caused by the amplification of the seed pulse. Collisional excitation is observed to re-establish in about ~ 1.5 ps the population inversion depleted during the amplification of the seed pulse. The measured gain-recovery time is compared to model simulations to gain insight on the population inversion mechanisms that create the transient gain in these amplifiers. This result indicates that an amplification scheme based on the continuous extraction of energy from a soft x-ray plasma-based amplifier by an stretched seed pulse has the potential to generate ultra-intense fully phase-coherent soft x-ray laser pulses.

8849-20, Session 5

Modeling and numerical simulations of seeded XUV lasers with the COLAX code: recent progress

Annie Klisnick, Andréa Le Marec, Univ. Paris-Sud 11 (France); Olivier Larroche, Commissariat à l'Énergie Atomique (France)

Seeding of plasma-based XUV lasers with a femtosecond coherent external pulse, such as high-order harmonic radiation, is a very promising technique to drive these lasers towards better beam quality and significantly enhanced peak power. Experimental progress toward these goals requires support from numerical simulations able to describe the

strongly non-linear regime of amplification induced by seeding in a high-gain, narrow-band amplifier. Such simulations are based on a Maxwell-Bloch description of the amplified field and atomic polarization. We describe recent studies performed with our recently upgraded COLAX code to investigate the coherence and temporal behaviour of the seeded XUV laser pulse.

8849-21, Session 5

Wavefront of seeded soft x-ray laser based on solid-plasma amplifier

Lu Li, Ecole Polytechnique (France) and Lanzhou Univ. (China); Yong Wang, Shoujun Wang, Colorado State Univ. (United States); Eduardo Oliva, Thi Thu Thuy Le, David Ros, Gilles Maynard, Univ. Paris-Sud 11 (France); Bitao Hu, Lanzhou Univ. (China); Jorge J. Rocca, Colorado State Univ. (United States); Philippe Zeitoun, Ecole Polytechnique (France)

This experiment set out to determine the wavefront of seeded soft x-ray laser with solid-plasma amplifier. The 43rd harmonic signal from neon gas jet has been amplified by seeded to the molybdenum plasma. Hartmann wavefront senor with accuracy at λ/50 rms was employed to measure the wavefront of both high harmonics and amplified soft x-ray lasers. Significant improvement of wavefront after plasma amplifier (from HHG 0.51λ rms to seeding 0.23λ rms) has been observed in agreement with previous studies on gas ampifier. In addition, we measured the wave front for plasma lengths ranging from 2.5 to 5 mm and observed a net improvement for the longest plasmas. Optimization of wave front versus seeding time has been completed showing a slight influence of this parameter. For every condition, wave fronts have been decomposed on the first Zernike polynomials (up to coma at 0°) giving better insight on the spatial filtering achieved during amplification. Finally, soft x-ray source structures have been retrieved from the wave fronts and intensity maps.

8849-22, Session 5

High-average-power 100-Hz repetition rate table-top soft x-ray lasers *(Invited Paper)*

Jorge J. Rocca, Brendan A. Reagan, Keith Wernsing, Yong Wang, Liang Yin, Shoshun Wang, Mark Berrill, Mark R. Woolston, Alden H. Curtis, Federico J. A. Furch, Vyacheslav N. Shlyaptsev, Brad M. Luther, Dinesh Patel, Mario C. Marconi, Carmen S. Menoni, Colorado State Univ. (United States)

The generation of high average power beams of coherent soft x-ray radiation in a compact set up is of high interest for numerous applications. The average power of plasma-based soft x-ray lasers has been limited by the repetition rate of the solid state optical lasers that drive them, which typically comprise either flash-lamp-pumped neodymium-doped glass or titanium sapphire that are limited to about 10 Hz. To overcome this limitation we have developed a compact, directly diode-pumped CPA laser based on cryogenically-cooled Yb:YAG amplifiers that produces 1 Joule, 5 ps FWHM duration, λ=1.03 μm laser pulses at a record high repetition rate of 100 Hz. This laser was employed to drive a gain-saturated 18.9 nm soft x-ray laser in a nickel-like molybdenum plasma producing a record average power of ~0.15 mW [1]. Strong lasing at 13.9 nm was also achieved at 100 Hz repetition rate from a silver plasma. Optimized pump conditions for increased average power will be discussed. These results increase the repetition rate and average power of compact, sub-20 nm lasers by about an order of magnitude and are expected to extend the use of these lasers to new applications

This work was supported by the NSF ERC for Extreme Ultraviolet Science and Technology and by the Chemical Sciences, Geosciences and Biosciences Division, Office of Basic Energy Sciences, U.S. Department of Energy using equipment developed under NSF Award MRI-ARRA 09-561

8849-10, Session 6

Performance of a beam-sharing monochromator at the Linac Coherent Light Source

Roberto Alonso-Mori, SLAC National Accelerator Lab. (United States); Vladimir D. Blank, Technological Institute of Superhard and New Carbon Materials (Russian Federation); Sebastien Boutet, Matthieu Chollet, Yiping Feng, David M. Fritz, Henrik T. Lemke, Marc Messerschmidt, Aymeric Robert, SLAC National Accelerator Lab. (United States); Yuri V. Shvyd'ko, Argonne National Lab. (United States); Marcin Sikorski, Sanghoon Song, SLAC National Accelerator Lab. (United States); Stanislav Stoupin, Argonne National Lab. (United States); Sergey A. Terentyev, Technological Institute of Superhard and New Carbon Materials (Russian Federation); Tim B. van Driel, Technical Univ. of Denmark (Denmark); Garth J. Williams, Diling Zhu, SLAC National Accelerator Lab. (United States)

A diamond double crystal monochromator was recently commissioned at the Linac Coherent Light Source (LCLS). A 100 um thick strain-free single crystal diamond was used as the first crystal to split the beam: it reflects a narrow bandwidth and allows the remaining part of the incident spectrum to be delivered to downstream instruments. This would thus potentially allow simultaneous operation of several instruments at LCLS. We report here the initial characterizations of the monochromator performance including its bandwidth, throughput in both branches, and its impact on the wavefronts. Its implications on experimental operation and limitations are also discussed.

8849-23, Session 6

Status and achievements at FERMI@Elettra: the first double cascade seeded EUV-SXR FEL facility open to users *(Invited Paper)*

Cristian Svetina, Sincrotrone Trieste S.C.p.A. (Italy) and Univ. degli Studi di Trieste (Italy); Marco Zangrando, Sincrotrone Trieste S.C.p.A. (Italy) and IOM-CNR (Italy); Nicola Mahne, Lorenzo Raimondi, Sincrotrone Trieste S.C.p.A. (Italy); Luca Giannessi, Sincrotrone Trieste S.C.p.A. (Italy) and ENEA C.R. Frascati (Italy); Carlo Callegari, Sincrotrone Trieste S.C.p.A. (Italy); Claudio Masciovecchio, Synchrotron Trieste S.C.p.A. (Italy); Maya Kiskinova, Sincrotrone Trieste S.C.p.A. (Italy)

FERMI@Elettra is the first VUV/soft X-ray FEL source based on the High-Gain Harmonic Generation (HGHG) configuration, in which an external UV laser is used to trigger the emission process. It is composed by two undulatory chains: the low energy branch (FEL1) covering the wavelength range from 20 nm up to 65 nm, and the the high energy branch (FEL2, employing a double stage cascade), covering the wavelength range from 4 nm up to 20 nm. At the end of 2012 FEL1 has been opened to external users while FEL2 has been turned on for the first time having demonstrated that a double cascade scheme is suitable for generating high intensity coherent FEL radiation. The Photon Analysis Delivery and Reduction System (PADReS) is used to provide information about the photon beam (intensity, spatial distribution and position, spectral content, transverse coherence,…) as well as for delivering and focusing the FEL radiation inside the experimental end-stations.

In our presentation we will share our experience and will show our most recent results for both FERMI FEL1 and FEL2 sources. We will also

present a brand new machine scheme that allows to perform two-colour pump and probe experiments as well as the first experimental results.

Single shot spectrum measurements of the fundamental, second, and third harmonic at a hard x-ray free electron laser

Matthieu Chollet, Henrik T. Lemke, Roberto Alonso-Mori, Marcin Sikorski, Yiping Feng, Aymeric Robert, Diling Zhu, SLAC National Accelerator Lab. (United States)

Most of the experiments performed to date at the Linac Coherent Light Source (LCLS) in the hard X-ray regime use the radiation from the fundamental wavelength. It was however shown that non-negligible levels of higher harmonics are also present [1] and can be used for experiments at higher photon energies beyond the reach of the fundamental wavelength. LCLS uses the principle of Self Amplified Spontaneous Emission (SASE), which introduces shot-to-shot fluctuations of many beam properties such as : pulse energy, pulse duration, spatial and temporal profile and spectral content. The understanding of how higher harmonics behave and correlate with the fundamental provides valuable information that can be used to improve data analysis, noise and background correction for LCLS operation.

We report here the measurement of both the fundamental and higher harmonic spectra of LCLS pulses using a single shot transmissive spectrometer for hard x-ray [2]. Two of those spectrometers based on bent thin Silicon crystals were used in this experiment. The first crystal dispersively diffracts the FEL spectrum at the fundamental wavelength, while higher harmonics are transmitted and diffract on a 2nd spectrometer ; thus enabling to record simultaneously both spectra from a single x-ray pulse.

LCLS mirror switching of x-ray beam

Jing Yin, Dehong Zhang, Brice T. Arnold, Bob Nagler, Hae Ja Lee, Eric C. Galtier, Philip A. Heimann, SLAC National Accelerator Lab. (United States)

The number of proposals for LCLS science has rapidly increased as all six LCLS x-ray instruments have come online. Only about 25 % of LCLS proposals can be allocated beamtime. One way to increase access is to share the x-ray beam between the different instruments. The purpose of this study is to quickly switch the x-ray beam between the Materials under Extreme Conditions (MEC) Instrument and the Coherent X-ray Imaging (CXI) or X-ray Correlation Spectroscopy (XCS) Instruments, in order that two of the instruments can perform experiments simultaneously. In the most common operational mode, the MEC Instrument uses one x-ray pulse every 10 minutes, limited by the repetition rate of the high pulse energy nanosecond laser system. The MEC M3H mirror steers the x-ray beam to the MEC Instrument from the XCS or CXI Instruments. If the M3H mirror could switch the x-ray beam to MEC within a fraction of the 10 minute waiting time, multiplexing of the x-ray beam would be achieved. The M3H mirror system has two motion stages for translation and rotation. The long path, 230 m, from the mirror to MEC hutch makes the pointing resolution and stability requirements challenging. The mirror translation speed and pointing reproducibility have been investigated. This study has shown that mirror translation can multiplex the LCLS x-ray beam.

8849-26, Session 6

Scanning coherent x-ray microscopy as a tool for XFEL-nanobeam characterization

Andreas Schropp, SLAC National Accelerator Lab. (United States); Robert Hoppe, Vivienne Meier, Jens Patommel, Frank Seiboth, Technische Univ. Dresden (Germany); Daniel Nilsson, Fredrik Uhlen, Ulrich Vogt, Hans M. Hertz, Royal Institute of Technology (Sweden); Hae Ja Lee, Bob Nagler, Eric C. Galtier, Brice T. Arnold, SLAC National Accelerator Lab. (United States); Ulf Zastrau, Royal Institute of Technology (Sweden); Jerome B. Hastings, SLAC National Accelerator Lab. (United States); Christian G. Schroer, Technische Univ. Dresden (Germany)

The emergence of x-ray sources of the fourth generation, so called x-ray free-electron laser (XFELs), comes along with completely new research opportunities in various scientific fields [1, 2, 3, 4]. In some experiments, however, the XFEL-beam needs to be additionally focused in order to increase the fluence incident on a sample. The characterization of these nanofocused beams is often crucial for a quantitative analysis of experimental data. Nevertheless, since the peak intensity of these focused beams is well above the damage threshold of any material, the characterization of a nano-focused XFEL-beam is experimentally challenging and, to date, was pursued primarily by imprint techniques providing only postmortem information of the intensity distribution [5].

During the last years, scanning coherent x-ray microscopy, also called ptychography [6, 7, 8], has revolutionized nanobeam characterization at third generation x-ray sources. The method yields the complete information on the complex-valued, nanofocused wave field with high spatial resolution [9, 10]. In an experiment carried out at the Matter in Extreme Conditions (MEC) instrument at the Linac Coherent Light Source (LCLS) we successfully applied the method to an attenuated nanofocused XFEL-beam with a size of 125 nm (FWHM), which was created by a set of beryllium compound refractive lenses (Be-CRLs). The numerical analysis of the measured diffraction patterns gave access to the full caustic of the nanofocused beam. In a next step, the retrieved complex-valued wave field could be refined additionally for individual pulses.

Development of x-ray sources using PW laser systems at APRI GIST *(Invited Paper)*

Hyung Taek Kim, I Jong Kim, Chul Min Kim, Ki Hong Pae, Jae Hee Sung, Seong Ku Lee, Tae Jun Yu, Tae Moon Jeong, Jongmin Lee, Chang Hee Nam, Gwangju Institute of Science and Technology (Korea, Republic of)

We present the status and the plans of developing x-ray sources using intense laser pulses at Advanced Photonics Research Institute (APRI), GIST. Up to date, we successfully demonstrated x-ray lasers and

relativistic high-order harmonics using 100-TW laser system. Recently, a PW laser system with 30-J energy and 30-fs pulse duration was developed at APRI and it has been applied to generate highly energetic charged particles. We are planning to generate high flux x-ray/gamma-ray sources using the PW laser system and high-energy particles.

8849-29, Session 7

Investigation of pathways to local thermodynamic equilibrium of autoionizing states driven by intense XFEL irradiation of solid matter

Frank B. Rosmej, Univ. Pierre et Marie Curie (France) and Ecole Polytechnique (France); Frederick Petitdemange, Univ. Pierre et Marie Curie (France)

High intensity XFEL interaction with matter creates exotic states of matter on fs-time scales with subsequent relaxation of the photoionized core hole states of almost every atom [1]. The non-equilibrium properties are therefore also linked to the autoionization processes. We show that the generally accepted pathway to local thermodynamic equilibrium in atomic level population physics where collisions need to be much more important than corresponding radiative decay rates is in general invalid for autoionizing states. The almost evident inclusion of the non-radiative decay (autoionizing rate Γ) on the same footing like radiative decay rates by simply requesting that collisional rates need to be much larger than the sum of autoionizing and radiative decay rates (neC>> A+Γ, ne is the electron density, C the collisional rate coefficient, A the spontaneous transition probability) may provide order of magnitude misleading critical densities above with LTE holds. By means of a detailed analysis of the population channels of autoionizing states that include excited state coupling effects, we have identified the condition neC>> A+Γ as a theoretical limiting case that is almost never achieved under real experimental conditions. Detailed calculations are carried out for Al for typical XFEL irradiation parameters to illuminate the correct pathway to LTE for autoionizing states.

Stimulated electronic x-ray Raman scattering with x-ray free-electron lasers *(Invited Paper)*

Nina Rohringer, Max-Planck-Arbeitsgruppen für strukturelle Molekularbiologie (Germany); Clemens Weninger, Max-Planck-Arbeitsgruppen für strukturelle Molekularbiologie (Germany) and Max-Planck-Institut für Physik komplexer Systeme (Germany); Michael A. Purvis, Colorado State Univ. (United States); Duncan P. Ryan, Colorado State Univ. (United States) and Colorado State Univ. (United States); Victor Kimberg, Max-Planck-Arbeitsgruppen für strukturelle Molekularbiologie (Germany) and Max-Planck-Institut für Physik komplexer Systeme (Germany); Jorge J. Rocca, Colorado State Univ. (United States); Richard London, Lawrence Livermore National Lab. (United States)

X-ray free-electron lasers (XFELs) open the pathway to transfer non-linear spectroscopic techniques to the x-ray domain, to study the interplay of electronic and vibrational degrees of freedom by time-domain spectroscopy. A promising all x-ray pump probe technique is based on coherent electronic x-ray Raman scattering. The realization of these ideas is hampered by the extremely small inelastic scattering cross sections of x-rays with matter. A way to solve this problem is to stimulate the scattering process.

We present results on the first experimental demonstration of nearly saturated stimulated electronic x-ray Raman scattering using the LCLS XFEL. By tuning the relatively broad XFEL pulses to the core-excited Rydberg resonances in the pre K-edge region of neon, resonance scattered photons drive an avalanche of resonant inelastic x-ray scattering events. The scattering process is seeded by the spectral tail of the XFEL pulse, resulting in exponential amplification of the scattering signal with an enhancement of 6-7 orders of magnitude compared to the number of seed photons. By analyzing the line profile of the emitted radiation, the cross over from amplified fluorescence to a coherent resonance scattering was demonstrated. In case of coherent scattering, the scattered x-ray radiation shows a pulse-to-pulse fluctuation of the line shape and the spectral peak position, resulting from a stochastic detuning of individual spectral spikes of the XFEL from resonance. In combination with statistical covariance mapping, a high-resolution spectrum of the resonant inelastic x-ray scattering process can be obtained, opening the path to coherent stimulated x-ray Raman spectroscopy.

Coherent nanopatterning with table-top soft x-ray lasers *(Invited Paper)*

Mario C. Marconi, Lukasz Urbanski, Wei Li, Colorado State Univ. (United States); Aaron G. Stein, Brookhaven National Lab. (United States); Carmen S. Menoni, Jorge J. Rocca, Colorado State Univ. (United States)

We describe the last achievements in coherent lithography utilizing table top soft X ray lasers. This lithographic approach represents an interesting alternative for small scale nanofabrication of periodic structures. A periodic object composed of a two dimensional array of tiles forms highly accurate real images of itself by the classic Talbot self imaging effect. The Talbot images are used to print a photoresist deposited on a sample located in the Talbot plane where the self-image is produced. The print in is used to further process the sample and define periodic metallic nanostructures.

The diffractive mask was fabricated on a 25 nm thick membrane of Si3N4 using standard electron-beam lithography. The pattern was directly created in a 65 nm thick hydrogen silsesquioxane (HSQ) photoresist layer, or alternatively was etched through to create a self-standing diffractive mask. A soft X-ray =46.9 nm capillary discharge laser was used to replicate the Talbot mask.

We will present experimental results showing that the Talbot lithography method is scalable in size changing the convergence of the illumination beam, achieving de-maginification factors in the print of about 20%. Also this lithographic technique is capable to produce defect-free prints. Different examples of periodic structures fabricated in Au and Ag will also be presented.

Two-zone-plate interferometer for EUV image-plane holographic microscopy

Jaroslav Nejdl, Institute of Physics of the ASCR, v.v.i. (Czech Republic) and Czech Technical Univ. in Prague (Czech Republic); Isela D. Howlett, Colorado State Univ. (United States); Erik H. Anderson, Weilun Chao, Lawrence Berkeley National Lab. (United States); Mario C. Marconi, Jorge J. Rocca, Carmen S. Menoni, Colorado State Univ. (United States)

We present a new interferometric technique employing coherent radiation from a table-top capillary discharge Ar laser operating at 47nm. Using zero and first diffraction orders of successively placed binary Fresnel zone plates that act like both focusing elements and beam-splitters we can acquire an image-plane hologram of the sample evaluating quantitatively both the phase and amplitude effects of the sample. Besides the theoretical estimation of the performance of the technique we report a test experiment with nanostructured Si sample. The estimated spatial resolution of our setup reached 100nm due to high numerical aperture of the objective zone plate and short wavelength of the radiation. Although, the pulse duration of the Ne-like Ar laser was 1.5ns setting the limit of temporal resolution of our setup when operated in single-shot regime, the demands on longitudinal coherence of the interferometer are due to its in-line configuration rather low enabling to reach 100fs temporal resolution, if appropriate source of radiation was used.

8849-34, Session 8

Tabletop coherent diffraction imaging with a discharge plasma EUV source

Larissa Juschkin, Lars Loetgering, RWTH Aachen (Germany); Jianwei Miao, Univ. of California, Los Angeles (United States)

We present results of lensless imaging experiments using a high-frequency tabletop discharge plasma based partially coherent extreme ultraviolet (EUV) source. Influence of spatial and temporal coherence is investigated experimentally and compared with theoretical predictions for two emission spectra of different bandwidth at 11 nm and 17.3 nm. By using different illumination pinhole geometries, beams of varying degree of spatial coherence are generated and utilized to obtain far field diffraction patterns for iterative reconstruction of the complex transmission function of a test object. The presented experiments explore the feasibility of coherent diffraction imaging (CDI) with high brightness sources emerged from the technology development of EUV lithography, paving the way for laboratory-scale CDI applications in nanoscience and metrology.

8849-35, Session 8

Recent developments in the theory of coherent x-ray imaging

Igor A. Artyukov, P.N. Lebedev Physical Institute (Russian Federation); Alexander S. Busarov, National Research Nuclear Univ. MEPhI (Russian Federation); Ruslan M. Feshchenko, Nikolay L. Popov, Alexander V. Vinogradov, P.N. Lebedev Physical Institute (Russian Federation)

Coherent imaging is a well developed technology both in the visible and X-ray ranges. It can be applied if coherent sources such as lasers, harmonic generators or 3rd and 4th generation light sources are used for object illumination. Coherent imaging provides a combination of useful modalities: phase retrieval, lensless imaging, wavelength resolution and also reduces the radiation loading on the object and environment. Traditionally coherent imaging was used mainly for investigation of transparent objects. Our approach based on the parabolic wave equation allows extending the method to imaging in the reflection mode including the objects illuminated at grazing angles of incidence. The earlier suggested “transparent” boundary conditions we widely use for analysis and computing of object to detector wave field propagation. If the object is tilted in respect to the beam k-vector the wave field is found in the form generalizing the Fresnel integral widely used in the theory of transmission mode coherent imaging. The inversion of this new expression for the wave field is a basis for solution of the phase retrieval problem in the case of obliquely illuminated objects. The optical schemes for coherent reflection imaging are presented and relations between coherent and geometrical optics images are found. The results are illustrated with the help of computer codes developed for evaluation of spatial resolution and field of view.

Diamond crystals and a novel strain-free crystal mount for beam sharing double-crystal monochromator at LCLS

Stanislav Stoupin, Argonne National Lab. (United States); Sergey A. Terentyev, Vladimir D. Blank, Technological Institute of Superhard and New Carbon Materials (Russian Federation); Yuri V. Shvyd’ko, Lahsen Assoufid, Kurt Goetze, Argonne National Lab. (United States); Roberto Alonso-Mori, Matthieu Chollet, Yiping Feng, Henrik T. Lemke, Aymeric Robert, Sanghoon Song, Marcin Sikorski, Diling Zhu, Venkat Srinivasan, Sebastien Boutet, Marc Messerschmidt, Garth J. Williams, SLAC National Accelerator Lab. (United States)

A double-crystal diamond monochromator recently implemented at the LCLS enables splitting of the XFEL beam for simultaneous operation of two beamlines. The first crystal of the monochromator is a high quality type IIa diamond crystal plate with (111) surface orientation and of ~ 100 um thickness (to reduce absorbtion in the transmitted beam). We present details on the crystal fabrication, a novel method for strain-free crystal mount and results of x-ray characterization.

In particular, type IIa diamond crystal plates were cut by a laser into ~150 um thickness with small angular offset from (111) surface orientation (to enable polishing down to ~10 nm rms surface roughness.

The crystals were characterized by Lang x-ray topography and white-beam synchrotron topography. Plates with nearly perfect, defect-free regions of 2x5 mm2 were selected. These crystal plates were mounted on CVD diamond substrates and held gently by clams made out of diamond. The stiffness of the clamps was refined until strain-free rocking curve images (evaluated by doube-crystal x-ray topography) were obtained.

One of these assebmblies was installed in a vaccum tank of a large offset monochromator at the LCLS to enable beam sharing. Preliminary results indicate no substantial temperature gradients in the diamond-on-diamond assembly, absence of radiation damage and stable performance of the monochromator.

Beam characteristics of CAPEX XUV argon laser

Jiri Schmidt, Karel Kolacek, Oleksandr Frolov, Vaclav Prukner, Jaroslav Straus, Institute of Plasma Physics of the ASCR, v.v.i. (Czech Republic); Jan Kaufman, Czech Technical Univ. in Prague (Czech Republic)

The soft X-ray and extreme ultraviolet (XUV) lasers are sources, the applicability of which to technological and scientific research appeared just only about twenty years ago. These lasers were used for e.g. high-resolution microscopy, nanolithography, micro holography, and at very high plasma density measurements. The main advantages of these lasers are their availability, cost-effectiveness, and compactness. Such soft X-ray/XUV lasers have come in use in scientific and industrial laboratories for various applications.

Our department has been studying high-current capillary discharge as a XUV laser source over past 15 years. We are successfully operating two experimental devices CAPEX and CAPEX-U and we have observed a very strong amplification of Ne-like argon line at 46.9 nm on both these devices. While the experimental apparatus CAPEX-U has laser-triggered spark gap, which enables exact synchronization with diagnostics or other attached experiments, the apparatus CAPEX is capable to run at a higher repetition rate (~ 1 Hz).

This paper will report on the experimental results of CAPEX apparatus (repetitive lasing), mainly on its beam characteristics (e.g. laser beam profile, and laser pulse energy).

8849-44, Session PWed

Molecular dynamics simulation of cluster formation in femtosecond laser ablation

Daiki Hatomi, Naofumi Ohnishi, Tohoku Univ. (Japan); Masaharu Nishikino, Japan Atomic Energy Agency (Japan)

Laser ablation using an ultrashort pulse is expected to be applied in a wide range of areas and has been intensively investigated by a lot of experiments so far.

However, ablation processes by laser irradiation is complicated; therefore, a detailed analysis needs theoretical approaches especially for nonequilibrium and noncontinuum regime that appears in a picosecond-order dynamics.

In this paper, we present the ablation processes of platinum caused by a femtosecond laser pulse using a three-dimensional molecular dynamics model combined with the two-temperature model.

We can classify the ablation dynamics into three categories by clustering features which depends on a laser fluence above the ablation threshold.

With low laser fluence, spallation is found since the surface layer of the solid target breaks away due to a tensile pressure wave.

Homogeneous nucleation of nano-size clusters takes place with middle fluence in the liquid layer after the target surface layer is superheated and melts, although the surface layer fragments and vaporizes with higher fluence, which results in the gasification of the target.

We have examined the cluster formation of the ablated platinum above the ablation threshold by varying laser fluence and characterized these categories in terms of size distribution of the emitted cluster.

The size distribution obeys a power-law for the high laser fluence, while plateau region is found for the middle fluence.

Furthermore, the mechanism of the difference among three formation types may be explained -balance between the laser-induced pressure and binding energy of the atoms.

8849-36, Session 9

Multiple pulses pumping for application-oriented soft x-ray laser sources *(Invited Paper)*

Olivier A. Guilbaud, Sophie Kazamias, Moana Pittman, Kevin Cassou, Olivier Delmas, Sameh Daboussi, Univ. Paris-Sud 11 (France); Gabriel Cojocaru, Univ. Paris-Sud 11 (France) and INFLPR (Romania); Julien Demailly, Olivier Neveu, David Ros, Gilles Maynard, Univ. Paris-Sud 11 (France)

Low energy laser pulses, prior to the main high intensity pulse, are playing a crucial role in laser plasma interaction, as they can induce substantial modification of the target. Usually seen as detrimental, they are playing a dramatic and helpful role in soft x-ray laser generation both in QSS [1-2] and TCE [3-5] regimes. Implementing a train of prepulses in a controlled way, keeping the setup easy to use and stable is of great importance for a facility providing XUV beams for applications.

After a general overview of the technical solutions developed on the Laserix facility, we will illustrate how to choose one particular technique to match experimental requirements. Three examples will be highlighted. We will first present studies on a multiple pulse, single beam scheme and show how this configuration is helpful for reaching high stability and long operation cycle (at 10Hz) with a short preparation time. This kind of method has been successfully tested during experiments requiring an accumulation of a large number of shots (DNA sample irradiation, measurement of the reflectivity of a magnetic sample…)[6].

Pump-probe experiments are usually requesting auxiliary beams with a high contrast, which is in contradiction with most of the previously described methods. A very simple and efficient alternative has been demonstrated to overcome this problem. An auxiliary, low cost, Q-switch Nd:Yag laser, electronically synchronized with the IR laser, can play the role of a train of prepulses and can reach up to one third of the required ionisation level of Ni-like silver. In many ways this device is close to the one presented in [3] but the high contrast infrared pulse is preserved. Some variations of this technique will be detailed including the implementation of a short ionising pulse as proposed in reference [7]. The practice of this scheme will be illustrated by a pump-probe experiment dedicated to warm dense target XUV opacity probing [8].

Finally, soft x-ray laser seeding with high order harmonics could benefit from these methods. Effect on plasma uniformity, on gain linewidth, and on real seeding operations will be discussed.

8849-37, Session 9

Probing of laser-irradiated solid targets using coherent extreme ultraviolet radiation

Gregory J. Tallents, Lucy Wilson, The Univ. of York (United Kingdom)

It is planned that x-ray free-electron lasers (XFELs) will have large synchronised lasers, so laser-plasma probing studies using XFELs will be possible. Due to these future possibilities with XFELs and the possibility of undertaking such measurements with coherent harmonic radiation at existing facilities, the potential for coherent extreme ultra-violet (EUV) light in probing laser-produced plasmas is investigated in this work. A fluid code is used to model the interaction of a 35 fs, 2x1014 Wcm-2 800 nm laser pulse on an 800 nm thick aluminium target with a post processor used to calculate the refractive index and transmission of 45eV radiation through the target. The effects of EUV radial phase variations at the rear of the target on the intensity distribution at a detector 1.5m from the target are studied. The irradiated aluminium target is found to have little effect on the transmission of the 45eV radiation, but there are significant phase retardation effects on the probing beam. These phase variations change the subsequent propagation of the radiation, suggesting a simple diagnostic measuring the far-field footprint of coherent EUV radiation passing through an irradiated target is sensitive to radial variations of the target heating. More general issues involved in the use of EUV light in probing plasmas of relevance to inertial fusion will also be discussed.

8849-38, Session 9

High energy density plasmas produced by x-ray and extreme ultraviolet lasers

Andrew K. Rossall, Valentin Aslanyan, Gregory J. Tallents, The Univ. of York (United Kingdom)

The work presented here examines the EUV/x-ray interaction within solid material, incorporating a detailed photoionization model into a pre-existing 2D Eulerian fluid code POLLUX. This code is used to investigate the ablation and expansion of the target material under intense EUV irradiation in order to investigate; the high aspect ratio, hole-drilling capabilities of an EUV/x-ray laser; the properties of the produced ‘bleaching wave’; the significant increase in ejected mass; and to simulate and interpret results from mass spectrometry measurements of solid density and expanding plume plasmas.

High energy density plasmas can be produced in both non-equilibrium

and equilibrium states through the interaction of x-ray and EUV laser sources with solid targets. EUV and x-ray lasers with wavelengths less than around 50nm can propagate through plasma at solid material density, as even with high levels of ionisation, the free electron density is sub-critical. Direct heating of solid density material arising from inverse bremsstrahlung, photoionization and autoionization can occur producing a rapid drop in opacity or a 'bleaching' of the target.

This work has significant impact potential in the areas of; the production of warm dense matter relevant to ICF; in high aspect ratio laser cutting, relevant to microelectromechanical systems; and use in plasma coating techniques.

8849-39, Session 9

Efficiently excited ultra-hot capillary discharge plasmas

Vyacheslav N. Shlyaptsev, Gonzalo Avaria, J. Li, Michael E. Grisham, J. Hughes, Colorado State Univ. (United States); F. Tomasel, Colorado State Univ, (United States); Jorge J. Rocca, Colorado State Univ. (United States)

The scaling of discharge plasma parameters represents a difficult task. As compared with laser-created plasmas, discharges impose more constrains. Aside from disruptive magnetic instabilities, which capillary plasmas can nearly miraculously overcome, in pinch discharges the two key mechanisms of energy deposition, magnetic pressure and Joule heating, are inter-dependent and both contribute to define energy distribution, plasma lifetime and other plasma parameters.

Motivated by the possibility of advancing x-ray lasers utilizing electrical discharges we are investigating a novel capillary discharge approach that promises to yield simultaneously high temperatures, high densities and high degree of ionization with high efficiency. To achieve this we are investigating a somewhat anti-intuitive approach, opposite to that of simply rising the peak current and following the route of large facilities with MA currents. Instead we are using ultrafast current pulses of modest amplitude and optimize the heating parameters to obtain increased efficiency of energy deposition into the plasma.

We developed an ultrafast electrical current pulser for driving into narrow bore channels discharges with an order of magnitude faster risetime than used in our previous Ne-like argon x-ray laser research. We are conducting experiments with currents of ~30-40 kA amplitude with the aim of demonstrating uniquely high plasma parameters, defined by electron temperatures and degree of ionization only comparable to those we have obtained using 200 kA current pulses. The results of detailed simulations will be compared to experiments, and applications to soft x-ray laser development will be discussed.

8849-40, Session 10

Development of coherent EUV scatterometry microscope with high-order harmonics for EUV mask inspection *(Invited Paper)*

Yutaka Nagata, RIKEN (Japan) and Univ. of Hyogo (Japan) and JST CREST (Japan); Tetsuo Harada, Masato Nakasuji, Hiroo Kinoshita, Univ. of Hyogo (Japan) and JST CREST (Japan); Katsumi Midorikawa, RIKEN (Japan)

Extreme ultraviolet (EUV) is the most promising technology for high volume manufacturing of next generation semiconductor. There is urgent need for stand-alone inspection tool for EUV mask. At wavelength inspection will be required for precision detection and evaluation of defects in EUV mask. A EUV mask consists of a patterned absorber on top of a reflective Mo/Si multilayer deposited on glass substrate. In the preliminary research, we have developed a coherent EUV scatterometry microscope (CSM) based on coherent diffraction imaging method using synchrotron radiation. Aerial images were reconstructed from diffraction images using phase retrieval algorithm. The CSM required spatially and temporally coherent EUV light to achieve a high spatial resolution. Since the synchrotron radiation was partially coherent, EUV power on the mask was reduced to about 1 pW as a result of improvement of the coherence. But coherence of the EUV source was still not sufficient for the detection of small defects. We have developed a coherent high-order harmonics generation system as a practical coherent EUV light source for the CSM. Low divergence, spatially coherent, high-order harmonics (HHs) have been generated using commercial sub-TW laser system. The CSM equipped with 13.5 nm HHs dramatically improved the contrast ratio of diffraction images. Defect signals were observed from the 2-nm width line-defect in the 88-nm line-and-space (L/S) pattern. The diffractive light patterns caused by hole defects were distinguished with intense interference patterns caused by two-dimensional periodic hole-patterns. We also observed bridge defects in the 88-nm L/S pattern.

8849-41, Session 10

X-ray Thomson scattering for partially ionized plasmas including the effect of bound levels

Joseph Nilsen, Lawrence Livermore National Lab. (United States); Walter R. Johnson, Univ. of Notre Dame (United States); K. T. Cheng, Lawrence Livermore National Lab. (United States)

X-ray Thomson scattering is being developed as a method to measure the temperature, electron density, and ionization state of high energy density plasmas such as those used in inertial confinement fusion. Most experiments are currently done at large laser facilities that can create bright X-ray sources, however the advent of the X-ray free electron laser (X-FEL) provides a new bright source to use in these experiments.

One challenge with X-ray Thomson scattering experiments is understanding how to model the scattering for partially ionized plasmas in order to include the contributions of the bound electrons in the scattered intensity. In this work we take the existing models of Thomson scattering that include elastic ion-ion scattering and the electron-electron plasmon scattering and add the contribution of the bound electrons in the partially ionized plasmas. We will first look at the bound electron contributions to beryllium by analyzing existing experimental data. We then consider several higher Z materials such as Cr and predict the existence of additional peaks in the scattering spectrum that requires new computational tools to understand. We will also show examples of experiments in C and Al that have bound contributions that change the shape of the plasmon peaks in a way that would change the plasma temperature and density inferred by the experiment.

8850-1, Session 1

Target alignment and positioning on the Astra-Gemini facility

Nicola Booth, Daniel Symes, David Neely, Oliver Ettlinger, Andrew Sellers, Central Laser Facility (United Kingdom)

The drive to higher intensities and the move to shorter focal length reflective optics for focussing in solid target interactions are increasingly important for studies into high intensity secondary source generation, QED studies and the push for inertial confinement fusion. This then presents a significant problem for accurate target positioning. Commercial imaging systems exist to aid the imaging and positioning of targets, however these are expensive and difficult to position areas of limited space.

At the Astra-Gemini system of the Central Laser Facility, the push for intensities above I = 10^21 Wcm^-2 with f/2 and f/1 optics means positioning targets within the Rayleigh range of < few microns. Here we present details of 2 systems implemented on the Astra-Gemini system to cheaply and accurately position targets with ≈ micron accuracy. These involve a cheap multi-achromat lens system with illumination at 800nm (the same as the Gemini IR beam) for imaging the rear of the target with high resolution and a multi-wavelength interferometer to enable sub-micron accuracy in the positioning of the front surface at the interaction point within the Rayleigh range. The combination of these two systems has significantly improved our accuracy in target positioning and has also resulted in a decrease in the time required to align targets between shots.

8850-2, Session 1

Evaluating radiation induced noise effects on pixelated sensors for the National Ignition Facility

Philip S. Datte, Anastacia M. Manuel, Mark J. Eckart, Mark C. Jackson, Hesham Y. Khater, Mark A. Newton, Lawrence Livermore National Lab. (United States)

The National Ignition Facility (NIF) utilizes several different pixelated sensor technologies for various functional measurement systems that include alignment cameras, laser energy sensors, and high-speed framing cameras. These systems remain in the facility where they are exposed to neutron radiation during a NIF shot. The image quality of the sensor degrades as a function of radiation induced damage. When a neutron strikes an individual pixel, it increases the noise by increasing its dark current response. This article reports on a figure-of-merit technique that aids in the tracking of the performance of pixelated sensors when exposed to neutron radiation from NIF. The technique displays the sensor dark current response normalized to the well depth versus the normalized number of pixels that have that response or better (lower noise). In essence, this is the cumulative sum for the probability distribution of pixels for dark current response. The sensor dark current growth can be displayed over time in a 2D visual representation for tracking radiation induced damage. Predictions to the increased noise as a function of neutron fluence for future NIF shots allow systems to simulate reduced performance for each of the individual camera applications. This predicted longevity allows for proper management of the camera systems.

8850-3, Session 1

Nuclear background effects on plasma diagnostics for megajoule class laser facility

Adrien Rousseau, Stephane Darbon, Philippe Paillet, Commissariat à l'Énergie Atomique (France); Sylvain Girard, Univ. Jean Monnet Saint-Etienne (France); Jean-Luc Bourgade, Mélanie Raine, Olivier Duhamel, Commissariat à l'Énergie Atomique (France); Vincent Goiffon, Pierre Magnan, Aziouz Chabane, Paola Cervantes, Institut Supérieur de l'Aéronautique et de l'Espace (France); Matthieu Hamel, Commissariat à l'Énergie Atomique (France); Jean Larour, UPMC Sorbonne Univ. (France)

Estimating the vulnerability is a key challenge for plasma diagnostics designed to operate in radiative background associated with megajoule class laser facility. Since DT shots at OMEGA laser facility reproduces the perturbing source expected in the first 100 nanoseconds of a typical DT shot on National Ignition Facility and Laser MegaJoule, vulnerability of diagnostic elements such as optical relays or optical analyzers are experimentally studied and if necessary hardening approaches initiated to ensure their survivability at higher constraints.

A set of three different optical relays associated with optical analyzer have be exposed to 5.10^13 neutrons yield at 5 m from the OMEGA target chamber center. Degradations are observed, especially for the recording device (CCD) for which dynamic range appears proportional to the neutron fluence. An optical architecture is then extremely sensitive to the radiative environment and in standard configuration will lead to complete failure of diagnostic when extrapolating to NIF or LMJ fluence.

A new mitigation technique improving radiation tolerance of diagnostics based on CMOS image sensor has been tested at OMEGA facility to overcome this vulnerability problem. Charges generated by particles impinging the sensor are removed thanks to a custom global reset functionality. The image, free of transient degradation, is recorded only when the radiation constraints have faded away with a long persistence scintillator. In complement, simulations are led to predict the remaining transient and permanent degradation of image sensors in complex radiative background.

8850-4, Session 1

Diagnostic Instrument Manipulator (DIM) upgrades for reliability and operational efficiency in a radiological contamination environment at the National Ignition Facility

Robert E. Plummer, Lawrence Livermore National Lab. (United States)

The Diagnostic Instrument Manipulators (DIMs) are two-staged, telescoping systems that allow the precise alignment and positioning of various x-ray, optical, nuclear, and other diagnostics in the National Ignition Facility (NIF) Target Chamber. Designed to be reconfigurable and exchangeable between NIF experiments, the second stage of the DIM is referred to as the Diagnostic Load Package (DLP), which is most often comprised of a cart, diagnostic, and detachable snout. As experiments continue to increase radiation levels, various upgrades have been made to the DIMs to improve reliability and operational efficiency. These upgrades reduce worker exposure and increase experimental shot rates. Specific to this paper, the design and operation of dedicated DLP handling and storage units (DHUs and DSUs) are discussed in addition to their transport equipment. Hardware and process improvements for reduced worker exposure during general DIM access are also featured. Finally, the DLP limit switches have been upgraded to magnetically-

actuated proximity sensors for reliability, improved shot rate, and increased user flexibility.

This work is performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

8850-5, Session 2

Calibration and modeling of x-ray and neutron sensitivity of imaging plates

Nobuhiko Izumi, Gary F. Stone, Brian R. Maddox, David K. Bradley, Perry M. Bell, Lawrence Livermore National Lab. (United States); Joshua J. Lee, Edward Don M. Lomano, National Security Technologies, LLC (United States)

An imaging plate (IP) is a phosphor with signal storage capability. Due to their immunity to electric-magnetic-interference, IPs have been used in various laser-plasma experiments as a time integrating detector for x-ray imaging and electron spectroscopy.

In a sensitive region of an IP, electrons produced by ionizing radiation are trapped by color centers (vacancies of F,Br, or I). When the plate is scanned with a laser beam (650nm), those trapped electrons are re-excited and cause photo stimulated luminescence (~390 nm) by recombination. Each type of IP has different composition and physical thickness. The readout efficiency of the stored signal also depends on laser power, spot size, and scanning speed of the scanner. A signal fading due to thermal excitation of trapped carrier also affects the sensitivity of IP's. In order to extract quantitative information from IP data, it is crucial to calibrate the sensitivity of the plate together with the scanner. We present an easy to use IP calibration station based on radioactive isotopes (55Fe, 109Cd, and 241Am). This apparatus provides a convenient setup for measuring absolute sensitivity of the IP and the associated scanner. Comparison of experimental results and Monte Carlo simulations will be reported. An absolute sensitivity measurement of IPs for fast neutrons will also be reported. Prepared by LLNL under Contract DE-AC52-07NA27344.

8850-6, Session 2

Calibrating image plate sensitivity in the 700 to 5000 eV spectral energy range

Michael J. Haugh, Joshua J. Lee, Edward D. Romano, National Security Technologies, LLC (United States); Marilyn B. Schneider, Lawrence Livermore National Lab. (United States)

This paper describes a method to calibrate image plate sensitivity for use in the low energy spectral range. Image plates can be a valuable tool as a detector for plasma physics studies. Their advantages of large dynamic range, high stopping power, and resistance to neutron damage sometimes outweigh the problems of limited resolution and the remote processing required. The neutron damage resistance is required when using the Static X-ray Imager on the National Ignition Facility (NIF) target chamber at LLNL on high yield shots.

Type MS and SR image plates were calibrated and published for spectral sensitivity from 8 to 80 keV using the NSTec High Energy X-ray (HEX) source1, a fluorescer type X-ray source. Models MS and SR have a plastic coating, model TR has no coating. The models SR and TR were calibrated at the low energy range using a diode source and a band pass filter. The X-ray flux is measured using a photodiode that is traceable to NIST. The spectrum for each X-ray band is measured using a silicon drifted detector. The image plate metastable states are converted to digital images using a standard reader. The results of these measurements will be presented and the uncertainties in the measurement will be discussed. The results will be compared to other measurements and estimation methods.

1. B. R. Maddox, H. S. Park, B. A. Remington, N. Izumi, S. Chen, C. Chen, G. Kimminau, Z. Ali, M. J. Haugh, and Q. Ma, Rev. Sci. Instrum., 82, 023111 (2011)

8850-7, Session 2

Development of CCD cameras for soft X-ray imaging at the National Ignition Facility

Alan T. Teruya, Nathan E. Palmer, Marilyn B. Schneider, Lawrence Livermore National Lab. (United States); Gary R. Sims, Spectral Instruments, Inc. (United States); Michael J. Haugh, Edward D. Romano, Dennis T. Palmer, National Security Technologies, LLC (United States)

The Static X-Ray Imager (SXI) is a National Ignition Facility (NIF) diagnostic that uses a CCD camera to record time-integrated X-ray images of target features such as the laser entrance hole of hohlraums. SXI has two dedicated positioners on the NIF target chamber for viewing the target from above and below, and the X-ray energies of interest are 870 eV for the "soft" channel and 3 – 5 keV for the "hard" channels. The original cameras utilize a large format back-illuminated 2048 x 2048 CCD sensor with 24 micron pixels. Since the original sensor is no longer available, an effort was recently undertaken to build replacement cameras with suitable new sensors. Three of the new cameras use a commercially available front-illuminated CCD of similar size to the original, which has adequate sensitivity for the hard X-ray channels but not for the soft. For sensitivity below 1 keV, LLNL had additional CCDs back-thinned and converted to back-illumination for use in the other two new cameras. In this paper we describe the characteristics of the new cameras and present performance data (noise, dynamic range, and energy sensitivity) for the front- and back-illuminated cameras, with comparisons to the original cameras. Work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

8850-8, Session 2

Performance of CID camera X-ray imagers at NIF in a harsh neutron environment

Nathan E. Palmer, Marilyn B. Schneider, Kenneth W. Piston, James D. Moody, Lawrence Livermore National Lab. (United States); Michael J. Haugh, Joshua J. Lee, National Security Technologies, LLC (United States)

Charge-injection devices (CIDs) are 2D imaging sensors similar to CCDs, but their distinct architecture makes CIDs more resistant to ionizing radiation. CID cameras have been used extensively at the OMEGA Laser Facility for X-ray imaging with neutron fluences at the sensor approaching 10^9 neutrons/cm2 (DT, 14.1 MeV). A CID Camera X-ray Imager (CCXI) system has been designed and implemented at NIF that can be used as a rad-hard electronic-readout alternative for time-integrated X-ray imaging. This paper describes the design and implementation of the system, sensitivity of the sensor for X-rays in the range of 2 – 15 keV, and data acquired on NIF shots over a range of neutron yields. The upper limit of neutron fluence at which CCXI has acquired useful data is somewhat lower than the expected 109 neutrons/cm2 and there are noise problems that require further work, but the sensor has proven to be very robust in surviving high yield shots with minimal damage. This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

8850-9, Session 2

Characterization of a megapixel CMOS charge dump and read camera

Joseph R. Kimbrough, Perry M. Bell, James D. Moody, Mai Thao, Lawrence Livermore National Lab. (United States)

The National Ignition Facility is developing a radiation-hardened megapixel CMOS imaging camera to replace CCD cameras currently

used in x-ray streak cameras and gated imaging detectors. A prototype radiation tolerant camera based on a 2k by 2k CMV4000 sensor from CMOSIS Inc. has been built. Camera electronic parts were selected to operate up to 10 krad(Si). The sensor and camera incorporate a fast charge and dump of the sensor pixels, followed by image readout. This allows the dumping of charge due to the prompt radiation noise and then readout of the longer persistence phosphor signal from the x-ray diagnostics. Characterization of the sensor and gated performance were completed. This will be followed with characterization of radiation effects on the sensor and camera.

Lawrence Livermore National Laboratory is operated by Lawrence Livermore National Security, LLC, for the U.S. Department of Energy, National Nuclear Security Administration under Contract DE-AC52-07NA27344.

8850-10, Session 3

M-ARIANE: an x-ray imaging system for implosion experiments on National Ignition Facility at ignition neutron yields

Vladimir Smalyuk, Lawrence Livermore National Lab. (United States)

X-ray imaging diagnostics instruments will operate in a harsh ionizing radiation background environment during ignition experiments at the National Ignition Facility (NIF). These backgrounds consist of mostly neutrons and gamma rays produced by inelastic scattering of neutrons. An imaging system M-ARIANE, based on x-ray framing camera with film, has been designed to operate in such harsh neutron-induced background environments. Multilayer x-ray mirror and a shielding enclosure are the key components of this imaging system, designed to operate at neutron yields of ~1e18 on NIF. Modeling of the signal and noise of the x-ray imaging system will be presented.

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

8850-11, Session 3

Design and implementation of Dilation X-ray Imager for NIF "DIXI"

Marion J. Ayers, Sabrina R. Nagel, Perry M. Bell, Brian Felker, David K. Bradley, Kenneth W. Piston, Jake M. Parker, Lawrence Livermore National Lab. (United States)

Gated X-Ray imagers have been used on many ICF experiments around the world for time resolved images of the target implosions. DIXI (Dilation X-ray Imager) is a fixed base diagnostic that has been developed for use in the National Ignition Facility. The DIXI diagnostic is comprised of the following subsystems, pinhole imaging, filtering cassette, EMI shielding, pulsed dilation technology [1], detector head, detector head electronics, control electronics, CCD, film recording and nearly 1 ton of neutron shielding. Here we discuss the initial design, improvements implemented from rigorous testing, infrastructure and commissioning of DIXI on NIF.

8850-12, Session 3

X-ray yield measurements >6keV using a hardened streak camera at the National Ignition Facility

Shahab F. Khan, Andrew G. MacPhee, Kathy P. Opachich, Joseph R. Kimbrough, Joe P. Holder, Nobuhiko Izumi, Perry M. Bell, David K. Bradley, Lawrence Livermore National Lab. (United States); Joshua J. Lee, Michael J. Haugh, National Security Technologies, LLC (United States)

A neutron hardened x-ray streak camera has been used to report x-ray burn duration and time of peak emission from imploding ICF capsules at The National Ignition Facility with ? <30 ps. Recent calibration of the instrument using a NIST traceable High Energy X-ray reference source (HEX, National Security Technologies) has enabled absolute capsule self-emission x-ray yield measurements (J/sr/keV). In this (talk/poster) we describe the calibration procedure used and present preliminary x-ray yield measurements from recent ICF implosions and compare results with time integrated yield data.

Lawrence Livermore National Laboratory is operated by Lawrence Livermore National Security, LLC, for the U.S. Department of Energy, National Nuclear Security Administration under Contract DE-AC52-07NA27344. National Security Technologies, LLC is operating for the U.S. Department of Energy under Contract No. DE-AC52-06NA25946.

8850-13, Session 3

A Kirkpatrick-Baez optic for x-ray diagnostic at NIF

Tommaso Pardini, Lawrence Livermore National Lab. (United States)

At the Lawrence Livermore National Laboratory (LLNL) we are developing a Kirkpatrick-Baez (KB) optic to be added to the suite of x-ray diagnostic instruments for the National Ignition Facility (NIF). The optic consists of 4 KB pairs made of spherically polished x-ray substrates. These substrates are multilayer-coated to allow steeper grazing angle geometries, and wavelength filtering. With this optic we aim at providing NIF with an alternative x-ray imaging technique to pinholes, improving both resolution and photon throughput. Extensive analysis has been conducted to define optic parameters compatible with the requirements of typical NIF experiments, such as core implosion and backlighter experiments. Here we intend to give an overview of the current design for the optic, and show simulation results of optic performance. Simulations have been obtained via ray tracing and wavefront propagation code.

8850-14, Session 4

Measuring the hot-electron population using time-resolved hard x-ray detectors on the NIF

Matthias Hohenberger, Univ. of Rochester (United States); Nathan E. Palmer, Gregory A. LaCaille, Eduard L. Dewald, L. Divol, Essex J. Bond, Tilo Doeppner, Lawrence Livermore National Lab. (United States); Joshua J. Lee, National Security Technologies, LLC (United States); C. A. Thomas, David K. Bradley, B. Kauffman, Lawrence Livermore National Lab. (United States); Christian Stoeckl, T. Craig Sangster, Univ. of Rochester (United States)

In laser-driven inertial confinement fusion, hot electrons can preheat the fuel and prevent compression of the capsule to ignition conditions. Measuring the hot-electron population in these high-intensity laser-driven experiments is key to understanding the laser–plasma interaction and the resulting target evolution. This can be inferred from the Bremsstrahlung generated by the interaction of the hot electrons with the target. At the National Ignition Facility (NIF), the filter-fluorescer x-ray diagnostic (FFLEX), a multichannel, hard x-ray spectrometer operating in the range of 20 to 500 keV, has recently been upgraded to fully time-resolved measurements of the Bremsstrahlung spectrum. We present characterization data for the upgraded setup, as well as recent results from ignition-scale experiments.

This work was supported by the U.S. Department of Energy Office of Inertial Confinement Fusion under Cooperative Agreement No. DE-FC52-08NA28302, the University of Rochester, and the New York State Energy Research and Development Authority. The support of DOE does not constitute an endorsement by DOE of the views expressed in this article. This work was performed under the auspices of the U.S. Department of Energy at Lawrence Livermore National Laboratory under contract DE-AC52-07NA27344.

8850-15, Session 4

Operational experience with optical streak cameras at the National Ignition Facility

Philip S. Datte, Peter M. Celliers, Daniel H. Kalantar, John D. Moody, Jarom Nelson, Randy T. Shelton, Lawrence Livermore National Lab. (United States)

The National Ignition Facility (NIF) utilizes several optical streak camera systems that collect data from (350nm to 1053nm) band during a full system laser shot. The camera systems are configured to collect single or multiple intensity profile signals, spectrally resolved data, spatially resolved interferometry data, and spatially resolved intensity data. The output data format represents the temporal resolution of the recorded event as a two dimensional image. For all these configurations, the time record ranges from 3ns to 100 ns. The precision of the recorded data requires several calibration techniques that provide an overall 2D space-time warp correction that is applied to the raw streak data. The article shall review the typical applications of the optical streak cameras on NIF, the performance of the calibration applied to shot data while in operation and the overall performance and reliability of the camera systems over the several years of operation.

8850-16, Session 4

Mach-Zehnder modulator performance on the NIF south pole bang time diagnostic

Bart Beeman, Andrew G. MacPhee, Joseph R. Kimbrough, Robert Chow, Essex J. Bond, Lawrence Livermore National Lab. (United States); K. Miller, National Security Technologies, LLC (United States); William R. Donaldson, Univ. of Rochester (United States)

We present performance data for Mach-Zehnder optical modulators fielded on the National Ignition Facility as a potential signal path upgrade for the South Pole Bang Time diagnostic. A single channel demonstration system has been deployed utilizing two modulators operating 90deg out of phase with each other extending the system dynamic range and improving signal to noise capabilities. X-ray target emission signals are split and fed into two recording systems; a reference CRT based oscilloscope and the dual Mach-Zehnder system. Results of bang-time determination from these two recording systems are compared and presented.

Lawrence Livermore National Laboratory is operated by Lawrence Livermore National Security, LLC, for the U.S. Department of Energy, National Nuclear Security Administration under Contract DE-AC52-07NA27344.

8850-17, Session 5

2D magnetic field warp reversal in images taken with DIXI (dilation x-ray imager)

Sabrina R. Nagel, Perry M. Bell, David K. Bradley, Marion J. Ayers, Brian Felker, Kenneth W. Piston, Gilbert W. Collins, Lawrence Livermore National Lab. (United States); Terance J. Hilsabeck, Joseph D. Kilkenny, Tae Chung, B. Sammuli, General Atomics (United States); Jonathan D. Hares, A. K. Dymoke-Bradshaw, Kentech Instruments Ltd. (United Kingdom)

DIXI utilizes pulse-dilation technology [1] to achieve x-ray imaging with temporal gate times below 10 ps [2]. The longitudinal magnetic field used to guide the electrons during the dilation process results in a warped image, similar to an optical distortion from a lens. Since the front end, where x-rays are converted into electrons, at the beginning of the magnetic field determines the temporal resolution these distortions influence the temporal width of the images at the back end. Here we discuss the measurements and methods used to reverse the magnetic warp effect in the images gathered. The x-ray measurements were conducted using the COMET laser facility at the Lawrence Livermore National Laboratory.

Lawrence Livermore National Laboratory is operated by Lawrence Livermore National Security, LLC, for the U.S. Department of Energy, National Nuclear Security Administration under Contract DE-AC52-07NA27344. Work supported by U.S. Department of Energy under Contract DE-AC52-06NA27279.

LLNL-ABS- 618072

8850-18, Session 5

Investigation and suppression of artifacts in x-ray framing cameras due to advance radiation incident on microchannel plates

Laura Robin Benedetti, Charlie S. Anderson, Perry M. Bell, David K. Bradley, Charles G. Brown Jr., Steven M. Glenn, Joe P. Holder, Joseph R. Kimbrough, Michael P. Perkins, Robert B. Petre, Kenneth W. Piston, Natalia Simanovskaia, Lawrence Livermore National Lab. (United States)

We present evidence of an artifact in gated x-ray framing cameras that can severely impact image quality. This artifact typically presents as a high-intensity background over a narrow central portion of each microstrip of the framing camera and is correlated with experiments that produce a high flux of x-rays during the time before the framing camera is triggered.

Dedicated experiments using a short-pulse UV laser confirm that these artifacts can be most effectively produced by light that arrives ~1ns in advance of the voltage pulse that triggers the camera. This is consistent with these artifacts being the result of electrons produced uniformly at the MCP by early incident light and then focused by the EM fields of the camera.

We also describe efforts to suppress these artifacts by installing a conducting electrode in front of the active area of the framing camera. This device suppresses artifacts by attracting any electrons liberated from the MCP by x-rays that arrive before the camera is triggered. Preliminary experiments indicate that it does not otherwise affect the framing camera performance.

Modeling techniques have been applied to provide further insight. We have used a suite of techniques, including electrostatic, full-wave electromagnetic, and particle-in-cell simulations to understand the fields of the entire camera and the effect of our artifact suppression system. These simulations have shown that it is important to include the effects of components other than just the microstrips and microchannel plate in the head of the framing camera to obtain accurate EM fields.

Though this artifact was first identified on experiments at NIF due to the high-intensity of x-ray flux associated with hohlraum experiments that use >1MJ of laser energy, susceptibility to this artifact is nonetheless common to all pulsed framing cameras. Moreover, the artifact is sensitive to the specific time-dependent electromagnetic field within the entire camera head, something that varies substantially from camera to camera.

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344, LLNL-ABS-626612.

8850-19, Session 5

High-bandwidth impedance-matching circuits for National Ignition Facility gated x-ray framing cameras

Charlie S. Anderson, Joe P. Holder, Kenneth W. Piston, Natalia Simanovskaia, Gregory A. LaCaille, Perry M. Bell, Lawrence Livermore National Lab. (United States)

The National Ignition Facility (NIF) is the largest, most energetic laser facility in the world. To date, NIF has delivered 500 TW of peak power to target. Historically, NIF has been used for inertial confinement experiments and is capable of delivering 192 laser beams to compress a small capsule housed in several different hohlraum designs. In order to quantify the physics of NIF targets several diagnostics are deployed. Gated x-ray framing cameras are a critical target diagnostic used for imaging NIF targets.

Microstripline microchannel plate (MCP) detectors are used in the gated x-ray framing cameras. In order to achieve desired time gated images, the MCP must be pulsed electrically. This pulse must be high-bandwidth and high voltage (~1000V) to achieve the temporal resolution and optimum gain from the MCP. The microstripline structures applying gating voltage to the MCP "dielectric" are low impedance (<12 ohm) devices. The high voltage pulsers and interfacing transmission line components are as implemented as "standard" 50 ohm systems. Our new cameras use either a direct mismatch or transmission line transformer as an integral part of the detector housing allowing 50 ohm vacuum interfaces. Detector assembly and impedance matching circuit designs, parameters and implementations will be discussed.

Strip velocity measurements for gated x-ray imagers using short pulse lasers

Patrick W. Ross, Christopher T. Silbernagel, Michael Cardenas, Andrew S. Mead, Matthew C. Griffin, National Security Technologies, LLC (United States)

Strip velocity measurements of gated X-ray imagers using an ultra-short pulse laser are presented. Obtaining time-resolved X-ray images of inertial confinement fusion shots presents a challenge. One diagnostic developed to address this is the gated X-ray imager (GXD). The GXDs developed by Lawrence Livermore National Laboratory and Los Alamos National Laboratory use a microchannel plate (MCP) coated with a gold strip line that serves as a photocathode. GXDs are used with an array of pinholes which image onto various parts of the GXD image plane. As the pulse sweeps over the strip lines, it creates a time history of the event with consecutive images. To accurately interpret the timing of the images obtained using the GXDs, it is necessary to measure the propagation of the pulse over the strip line. The strip velocity was measured using a short pulse laser with a pulse duration of approximately 1-2 ps. The 200 nm light from the laser illuminates the GXD MCP. The laser pulse is split and a retroreflective mirror is used to delay one of the beam paths. By adjusting the distance to the mirror, one beam path is temporally delayed compared to the reference path. The retroreflective setup is calibrated using a streak camera with a 1 ns full sweep. Spatial resolution of 0.5 mm achieves a temporal resolution of ~5 ps on the GXD strip line.

This work was done by National Security Technologies, LLC, under Contract No. DE-AC52-06NA25946 with the U.S. Department of Energy. DOE/NV/25946--1720

8850-21, Session 6

Engineering precision relocation capability into a large-cantilevered telescoping diagnostic

Jake M. Parker, Marion J. Ayers, Todd A. Decker, Perry M. Bell, David K. Bradley, Tommaso Pardini, Thomas J. McCarville, Paul B. Mirkarimi, Randolph M. Hill, Lawrence Livermore National Security, LLC (United States)

The Kirkpatrick Baez Optics (KBO) diagnostic used on the National Ignition Facility has defined its mirror location repeatability requirements to be within a 150 micron spherical diameter each time that it is extended along its telescoping rail path during offline alignment and during its use on the NIF. When extended, the mirrors are located at the end of a Diagnostic Load Package, cantilevered more than three meters out from its bolted connection points. Discussed are the structural challenges and the mechanical design solutions that were implemented to achieve the 150 micron location repeatability goal of the diagnostic.

8850-22, Session 6

X-ray diffraction diagnostic design for the National Ignition Facility

Maryum F. Ahmed, Lawrence Livermore National Lab. (United States) and Akima Infrastructure Services, LLC (United States); F. Allen House, Raymond F. Smith, Lawrence Livermore National Lab. (United States); Zachary Lamb, Lawrence Livermore National Lab. (United States) and Akima Infrastructure Services, LLC (United States); David W. Swift, Lawrence Livermore National Laboratory (United States)

This paper describes the design considerations for Target Diffraction In-Situ (TARDIS), an x-ray diffraction diagnostic at the National Ignition Facility. A crystal sample is ramp-compressed to pressures between 10 and 30 Mbar and flooded with x-rays from a backlighter source foil. The crystal spectrography diffraction lines are recorded onto image plates. The crystal sample, filter, and image plates are packaged into one assembly, allowing for accurate and repeatable target to image plate registration. Unconverted laser light impinges upon the device, generating debris, the effects of which have been mitigated. Dimpled plastic blast shields, high strength steel alloy, and high-z tungsten are used to shield and protect the image plates. A tapered opening was designed to provide adequate thickness of shielding materials without blocking the drive beams or x-ray source from reaching the crystal target. The high strength steel unit serves as a mount for the crystal target and x-ray source foil. A tungsten body contains the imaging components. Inside this sub-assembly, there are three image plates: a 160 degree field of view curved plate directly opposite the target opening and two flat plates for the top and bottom. A polycarbonate frame, coated with the appropriate filter material and embedded with registration features for image plate location, is inserted into the diagnostic body. The image plate assembly is metrologized and then mounted to the target assembly via a kinematic coupling. Target metrology is then performed on the integrated assembly.

8850-23, Session 6

Design of survey x-ray spectrometer for NIF "NSS"

Shannon L. Ayers, Marilyn B. Schneider, Perry M Bell, David K. Bradley, Lawrence Livermore National Lab. (United States); John F. Seely, Uri Feldman, Walter L. Marlin, Artep, Inc. (United States)

Crystal spectrometers have been used on many experiments around the world to record spectra from laser-produced plasma. The NIF Survey Spectrometer (NSS) is being developed at the National Ignition Facility to record high resolution spectra covering a large x-ray range (6keV to 150keV). The NSS diagnostic is a Cauchois spectrometer consisting of a bent crystal in transmission geometry, a slit aperture, and a detector on the Rowland Circle. Two spectrometer channels with identical optical paths allow for the modular crystal design used in this instrument. Deployment of the NSS in the NIF facility will be implemented in two phases. Phase one is use of the NSS as a DIM based diagnostic and is currently being implemented. Phase two is a planned deployment of the NSS on a fixed port in a custom manipulator.

8850-24, Session 6

Implementation of a new multiple monochromatic x-ray 2D imager at NIF

George A. Kyrala, Drew Martinson, Frank Lopez, Tom Gravlin, Randall P. Johnson, Paul Polk, Thomas J. Murphy, Mark J. Schmitt, Los Alamos National Lab. (United States); F. Allen House, Reg Wood, Lawrence Livermore National Lab. (United States); Joshua J. Lee, Michael J. Haugh, National Security Technologies, LLC (United States)

We will describe the installation and wavelength calibration of a multiple monochromatic imager to be used on mix experiments at NIF. The imager works between 8-13 keV , has a spatial resolution of 16 micrometer and generates many images each with an energy bandwidth of ~80 eV . The images are recorded either on image plates or on gated x-ray detectors. We will describe: how we aligned the instrument on the bench using visible light, how we checked the alignment and determined the energy range using a k-alpha xray source, and how we installed and aligned the instrument to the NF target chamber

Sub-100-nm 3D-elemental mapping of frozen-hydrated cells using the bionanoprobe *(Invited Paper)*

Si Chen, Argonne National Lab. (United States); Ye Yuan, Northwestern Univ. (United States); Claus Flachenecker, Xradia, Inc. (United States); Junjing Deng, Rachel Mak, Tatjana Paunesku, Northwestern Univ. (United States); Qiaoling Jin, Argonne National Lab. (United States); Benjamin Hornberger, Xradia, Inc. (United States); Sophie C. Gleber, Deming Shu, Lydia Finney, Christian Roehrig, Jörg Maser, Barry Lai, Argonne National Lab. (United States); Keith Brister, Northwestern Univ. (United States); Stefan Vogt, Chris J. Jacobsen, Argonne National Lab. (United States); Gayle Woloschak, Northwestern Univ. (United States)

Hard X-ray fluorescence microscopy (XFM) is one of the most sensitive techniques to perform trace elemental analysis of biological samples, such as cells and tissues. As the spatial resolution increases beyond sub-micron scale, conventional sample preparation method, which involves dehydration, may not be sufficient for preserving subcellular structures in the context of radiation-induced artifacts. To reduce structural radiation damage, as well as allow imaging under hydrated "natural state" conditions, we have developed the Bionanoprobe (BNP), a hard X-ray fluorescence nanoprobe with cryogenic capabilities, dedicated to studying trace elements in frozen-hydrated biological systems. The BNP is installed at an undulator beamline at Life Sciences Collaboration Access Team at the Advanced Photon Source. It provides a spatial resolution of 30 nm for fluorescence imaging by using Fresnel zone plates as nanofocusing optics. Differential phase contrast imaging is carried out at the same time by using a quadrant photodiode mounted downstream of the sample. By employing a liquid-nitrogen-cooled sample stage and cryo specimen transfer mechanism, the samples are well maintained below 110 K during both transfer and X-ray imaging. The BNP is capable for automated tomographic dataset collection, which allows visualizing 3D distributions of elements inside the sample. In this presentation, we will describe the instrument design principles, quantify instrument performance, and report the early results obtained with the BNP from frozen-hydrated whole cells.

8851-2, Session 1

The CNM/APS hard x-ray nanoprobe: upgrades and current performance

Ian McNulty, Robert P. Winarski, Martin V. Holt, Volker Rose, Peter Fuesz, Argonne National Lab. (United States)

The Hard X-ray Nanoprobe at the Argonne Center for Nanoscale Materials and Advanced Photon Source is a precision platform for scanning probe and full-field microscopy with 8-12 keV x-rays at 30 nm spatial resolution [1]. This multimodel microscope is capable of scanning fluorescence, diffraction, and nanotomographic imaging experiments. The Nanoprobe position sensing and stabilization system was recently upgraded to a more compact and robust fiber-guided single-bounce laser interferometer that provides 50 nm position stability between the focusing optics and sample stage over periods exceeding 8 hours, with a travel range greater than 10 mm in all three axes. Other major upgrades to the Nanoprobe include a temperature controlled sample stage for in-situ measurements at cryogenic and high temperatures, and an integrated stage for combined scanning and tomographic imaging. In future, new nanofocusing optics with higher resolution (20 nm) and greater efficiency (5%) will be implemented. This talk discusses these upgrades and the current performance of the instrument with recent applications in nanoscience.

8851-3, Session 1

Status of the Nanoscopium scanning nanoprobe beamline of Synchrotron Soleil

Andrea Somogyi, Kadda Medjoubi, Cameron M. Kewish, Vincent Leroux, Marc Ribbens, François A. Polack, Jean-Pierre Samama, Synchrotron SOLEIL (France)

The Nanoscopium1,2 155 m-long scanning nanoprobe beamline of Synchrotron Soleil (St Aubin, France) is dedicated to quantitative multi-modal imaging in the 5-20 keV energy range. Two experimental stations, working in consecutive operation mode, will provide coherent scatter imaging and spectro-microscopy techniques for various user communities. Both continuous fast scanning3 with millisecond dwell times and nm precision step-scan mode operation will be provided for multiscale imaging; that is imaging large fields of view with moderate spatial resolution and sensitivity, followed by high spatial resolution and high sensitivity mapping of small volumes of interest. Next to fast scanning, cryogenic cooling will also reduce the radiation damage of sensitive samples during a measurement. Nanoscopium is in the construction phase, the first user experiments are expected in 2014. The main characteristics of the beamline and an overview of its status will be given in this contribution.

8851-4, Session 1

Optical performances and nanoprobe design of the NSLS-II SRX beamline

Vincent de Andrade, Juergen Thieme, Oleg Chubar, Yuan Yao, Brookhaven National Lab. (United States)

The Sub-micron Resolution X-ray spectroscopy beamline (SRX) is one of the seven project beamlines of NSLS-II at Brookhaven National Laboratory. SRX (ΔE: 4.65-23 keV) will address a wide variety of scientific applications probing heterogeneous complex systems from the meso to the nanoscale. Combined with state of the art optics, the ultralow emittance and stability of the NSLS-II source is particularly suitable for nanoprobes. The SRX main optical components consist of a horizontally focusing mirror creating a secondary source whose size is adjustable with slits, an ultra-stable horizontally deflecting monochromator and two sets of Kirkpatrick-Baez mirrors in two inline stations as focusing optics for operations requiring either high flux or high resolution. The presentation will focus first on the beamline layout that has been optimized with FEA, ray-tracing and wave front propagation simulations using respectively Shadow and SRW. The effects of partial coherence and the impact of the KB mirrors length (in contrast with thin lenses) were successfully modeled with the last SRW add-ons. Results demonstrate that the micro and nanoprobes will provide 1013 and 1012 ph/s respectively in a sub-micron

and a 50 nanometer spot, with an excellent energy resolution (close to the Darwin width of the selected crystals). At last, the nanoprobe design will be described in detail, with a highlight on interferometry tests performed on various sample stage assemblies that conducted our choices.

8851-5, Session 1

A next-generation in-situ nanoprobe beamline for the Advanced Photon Source

Jörg Maser, Barry Lai, Argonne National Lab. (United States); Tonio Buonassisi, Massachusetts Institute of Technology (United States); Zhonghou Cai, Si Chen, Lydia Finney, Sophie C. Gleber, Chris J. Jacobsen, Argonne National Lab. (United States); Conal Murray, IBM Thomas J. Watson Research Ctr. (United States); Curt A. Preissner, Deming Shu, David J. Vine, Stefan Vogt, Argonne National Lab. (United States)

The Advanced Photon Source is currently developing a suite of new hard x-ray beamlines, aimed primarily at the study of materials and devices under real conditions. One of the flagship beamlines of the APS Upgrade is the In-Situ Nanoprobe beamline (ISN beamline), which will provide in-situ and operando characterization of advanced energy materials and devices under change of temperature and gases, under applied fields, in 3D.

The ISN beamline is designed to deliver spatially coherent x-rays with photon energies between 4 keV and 30 keV to the ISN instrument. As an x-ray source, a revolver-type undulator with two interchangeable magnetic structures, optimized to provide high brilliance throughout the range of photon energies of 4 keV – 30 beamline, will be used. The ISN instrument will provide a smallest hard x-ray spot of 20 nm using diffractive optics, with sensitivity to sub-10 nm sample structures using coherent diffraction. Using nanofocusing mirrors in Kirckpatrick-Baez geometry, the ISN will also provide a focus of 50 nm with a flux of 8·1011 Photons/s at a photon energy of 10 keV, several orders of magnitude larger than what is currently available. This will allow imaging of trace amounts of most elements in the periodic system, with a sensitivity to well below 100 atoms for most metals in thin samples. It will also enable nano-spectroscopic studies of the chemical state of most materials relevant to energy science. We will discuss the beamline design, and discuss initial studies related to the science thrust of the ISN beamline.

8851-6, Session 2

Development of full-field hard x-ray microscopy with four aspherical mirrors

(Invited Paper)

Satoshi Matsuyama, Yoji Emi, Osaka Univ. (Japan); Yoshiki Kohmura, Kenji Tamasaku, Makina Yabashi, Tetsuya Ishikawa, RIKEN (Japan); Kazuto Yamauchi, Osaka Univ. (Japan)

We developed achromatic full-field hard X-ray microscopy on the basis of advanced Kirkpatrick-Baez (KB) mirrors consisting of four total-reflection mirrors. A designed optical system has 210x and 385x magnifications in vertical and horizontal directions, 0.0012 of numerical apertures in both directions and the working distance of 50 mm. Two elliptical mirrors and two hyperbolic mirrors with a figure accuracy of 2 nm were fabricated using elastic emission machining (EEM), microstitching interferometry (MSI) and relative-angle-determinable stitching interferometry (RADSI). We constructed an imaging system for magnifying transmission X-rays through a sample between the first and third experimental hutches of BL29XUL (SPring-8) to check the performance. A monochromatized X-ray of 10 keV was focused at the object plane using KB mirrors as a condenser. The transmission X-ray through the sample was collected by the advanced KB mirrors. The sample used was a Siemens star chart with a minimum resolution of 50 nm. Finally, a magnified image was formed at an X-ray CCD system placed ~45 m downstream of the objective. As a result, an X-ray image with a spatial resolution of ~150 nm was acquired. Also, no chromatic aberration was confirmed by taking images at an X-ray energy from 8 to 11.5 keV.

8851-7, Session 2

Efficient full-field x-ray microscopy with Zernike phase contrast having suppressed halo at Petra III

Ismo J. Vartiainen, Christian David, Paul Scherrer Institut (Switzerland); Alke F. Meents, DESY (Germany)

Imaging with multi-keV X-rays can reveal new nanoscale structural information even from thick specimens. However, due to a large penetration depth of X-rays, the absorption contrast is low especially when imaging biological samples. The contrast can be greatly enhanced similarly to the case of the visible light by applying phase contrast technique invented by Zernike. We report on the implementation of a full field X-ray microscope using Zernike phase contrast at 6.2keV at Petra III P11 in DESY Hamburg. The setup is well suited for high resolution imaging of samples that have low absorption contrast. Illumination of the sample is optimized by using a beam shaper as a condenser lens. This scheme enables uniform illumination over the FOV without scanning the optics. Illumination based on a beam shaper is very photon efficient compared to a classical hollow cone illumination as the whole incident beam can be exploited. Moreover, we show how the halo artifacts, often encountered in Zernike phase contrast can be suppressed by an optimized design. We present the first experimental results in phase and absorption contrast. In addition, quantitative phase imaging based on phase subtraction will be discussed.

8851-8, Session 2

Development of large-field high-resolution hard x-ray imaging microscopy with Fresnel zone plate objective

Yoshio Suzuki, Akihisa Takeuchi, Yasuko Terada, Kentaro Uesugi, Japan Synchrotron Radiation Research Institute (Japan)

Spatial resolution of hard x-ray imaging microscopy is now below 100 nm using Fresnel zone plate (FZP) objective lens. However, for practical use, large field of view (FOV) and high throughput are as important as the spatial resolution. The FOV of FZP microscope is restricted by the physical diameter of the objective FZP, and x-ray imaging detectors with high spatial resolution and high efficiency are very difficult at present. Therefore, a simple solution for the large-FOV high-resolution high-throughput x-ray microscopy is achieving large magnification by expanding the length of microscope system using a long experimental station. The beamline 37XU of SPring-8 was recently modified, and it is capable to construct very long (~30 m long) microscope system by combining three experimental hitches. Some configurations of microscope systems were tested. In a typical condition, a magnification of 133 and a FOV of 123 µm are attained using a FZP with a diameter of 310 µm and an outermost zone width of 100 nm. In this case, the effective pixel size is 60 nm. Spatial resolution was also evaluated by observing resolution test chart, and the spatial resolution of about 180 nm in full pitch of periodic object is achieved with an exposure time of 1 s. When a FZP with 50 nm outermost zone width, FOV of 50 µm and spatial resolution better than 100 nm are also achieved with an exposure time of 4 s. Three dimensional measurement by CT technique is also being carried out.

8851-9, Session 3

5D visualization of phase transitions *(Invited Paper)*

Yijin Liu, SLAC National Accelerator Lab. (United States); Junyue Wang, Carnegie Institution (United States); Wendy L. Mao, Stanford Univ. (United States); Wenge Yang, Carnegie Institution (United States)

The most substantial advancements in X-ray imaging techniques in the past decades are closely related to the availability of the synchrotrons and the development of advanced X-ray optics. The combination of the X-ray energy scanning and the full-field imaging technique has been demonstrated and recognized as a powerful tool for materials science studies. This functionality provides significant additional chemical information to the 3D geometry of the sample which is available through conventional imaging techniques. Utilizing to this newly developed imaging technique and a specially designed Diamond Anvil Cell pressure vessel, we investigated the pressure induced phase transition in BiNiO3 and present FIVE dimensional (X, Y, Z, Energy, Pressure) visualization, which is the morphology and chemical distribution change as a function of external pressure. We expect the presented method have significant impact in the application of X-ray imaging in materials science.

8851-10, Session 3

In-situ TXM of dynamic electrochemical systems

Johanna L. Nelson, Joy C. Andrews, Michael F. Toney, SLAC National Accelerator Lab. (United States)

Benefiting from the penetrating power, long focal length, and large depth of focus of transmission (hard) X-ray microscopy (TXM), we have developed a robust experimental program of in situ imaging. High resolution, in situ microscopy allows the visualization of dynamic systems in time, capturing a wealth of information inaccessible to ex situ imaging methods.

A global shift towards clean, renewable energy relies on the availability of cheap, high capacity, and high power energy storage devices. Li-ion batteries show promise as a clean alternative to the internal combustion engine; however, setbacks such as capacity fading hinder the full capability of these rechargeable batteries. With in situ TXM we can track the morphological changes of electrode material within operating Li-ion batteries such as the high capacity Li-S [1] and Li-Ge systems. By studying Li-ion batteries in situ we can better understand their electrochemical dynamics and failure mechanisms.

ZnO holds great promise for the development of low-cost electronic and photonic devices such as sensors, solar cells and light-emitting diodes because of its unique electrical, optoelectronic and luminescent properties. Using electrodeposition, ZnO nanostructures can be synthesized cheaply and the morphology can be precisely tuned by controlling deposition conditions (temperature, applied potential, time, and chemical composition of the deposition bath). By imaging this system in situ we can better understand the nucleation and growth of these nanostructures, which directly affect the properties of the final structure.

8851-11, Session 3

Development of in-situ full-field spectroscopic imaging analysis and application on Li-ion battery using transmission x-ray microscopy

Yu-Chen K. Chen-Wiegart, Jiajun Wang, Jun Wang, Brookhaven National Lab. (United States)

Transmission x-ray microscopy (TXM), a full-field x-ray imaging method, can provide sub-30 nm spatial resolution with hard x-ray. In addition to observing morphology, TXM can also provide elemental and chemical information via spectroscopic imaging. A newly developed TXM at beamline X8C of National Synchrotron Light Source has brought new capabilities. One of them is motorizing the detector along x-ray beam direction to provide a fixed magnification and therefore to utilize the best resolution of the instrument during spectroscopic imaging. With this new feature, we advanced in experimental method and image analysis to conduct TXM spectroscopic imaging in an in situ fashion. First, by tuning the incident x-ray energy, we obtain a series of energy-dependent full field images where each pixel (~10-40 nm in size) contains a full X-ray Absorption Near Edge Structure spectrum. By performing least-squares linear combination fitting on each pixel, the full-field imaging provides the capability to reveal the chemical state distribution within the sample. Then by conducting in situ imaging during a chemical/electrochemical reaction, a time-dependent and spatially resolved composition mapping series can be obtained. Coupling with the morphology observed during in situ imaging, we can correlate the reaction conditions, chemical states distribution change, and morphological evolution within the sample. We successfully applied this method to study the electrochemical evolution of CuO, an anode material of Li-ion battery, during the lithiation-delitiation cyling. This in situ TXM spectroscopic imaging can also be applied to other functional and energy storage materials where morphological and reduction-oxidation together play critical roles.

8851-12, Session 3

Development of in-line furnace for in-situ high-resolution x-ray microscopy

Christopher Eng, Yu-Chen K. Chen-Wiegart, Jun Wang, Brookhaven National Lab. (United States)

Full field transmission x-ray microscopy (TXM) is a newly developed x-ray imaging technique to provide quantitative and non-destructive 3D characterization of the complex microstructure of materials at nanometer resolution. A key missing component is an in situ apparatus enabling the imaging of the complex structural evolution of the materials and to correlate the structural change with a material's functionality under real operating conditions. This work describes the design of an environmental cell which satisfies the requirements for in situ TXM studies. The limited space within the TXM presents a spatial constraint which prohibits the use of conventional heaters, as well as requiring consideration in designing for safe and controlled operation of the system and alignment of the cell with the beam. A gravity drip-fed water cooling jacket was installed in place around the heating module to maintain critical components of the microscope at safe operating temperatures. A motion control system consisting of pulse width modulated DC motor driven XYZ translation stages was developed to facilitate fine alignment of the cell. Temperature of the sample can be controlled remotely and accurately through a controller to temperatures as high as 1200K. Heating zone measurement was carried out and shows a 500 x 500 x 500 µm3 homogeneous zone volume for sample area, which is a critical parameter to ensure accurate observation of structural evolution at nanometer scale with a sample in size of tens of microns. Application on Ni particles for in-situ oxidation experiment is also discussed.

8851-13, Session 4

High-resolution high-aspect ratio zone plate fabrication

Anne Sakdinawat, Chieh Chang, SLAC National Accelerator Lab. (United States)

We have developed a method to fabricate high aspect ratio, dense Si structures required for high resolution, high efficiency x-ray diffractive optics. This method utilizes metal assisted chemical etching and requires

only a single lithographic patterning step and a single pattern etching step. It is scalable to large-area features (larger diameter zone plates), and is compatible with programmable patterning (variations on zone plate structure), basic mechanical stacking, and metallization techniques such as atomic layer deposition or electroplating. Fabrication of very high aspect ratio structures exhibiting smooth sidewalls has been achieved at 1:50 aspect ratio for 50 nm half period structures. This fabrication method is a simple route to creating high resolution, high aspect ratio diffractive optics for various x-ray sources.

8851-14, Session 4

Deposition of elliptical-shaped KB mirrors for ESRF microfocus beamline ID13

Bing Shi, Jun Qian, Argonne National Lab. (United States); Raymond Barrett, Amparo V. Rommeveaux, Robert Baker, European Synchrotron Radiation Facility (France); Lahsen Assoufid, Argonne National Lab. (United States)

A pair of Platinum coated Kirkpatrick-Baez (KB) mirrors, a 40 mm long vertical focusing mirror (VF) and a 25 mm long horizontal focusing mirror (HF), was fabricated for the microfocus beamline ID13 at European Synchrotron Radiation Facility (ESRF) using magnetron sputtering technique. They were designed to achieve a focal spot size ≤ 150 x 150 nm2. Specially designed spherically shaped silicon substrates with were achieved to fit the compact KB system developed by the ESRF. For all of the previous KB mirrors that were fabricated using the profile coating method, typically two to more deposition steps are required. However, both of the two mirrors used just one deposition step and the surface figure (height) errors are 0.43 nm (VF) and 0.37 nm (HF) from the metrology measurements at Advanced Photon Source (APS). The metrology measurements from ESRF matched with APS's metrology results and also gave the rms slope errors of the two mirrors of 0.27 µrad (VF) and 0.25 ?rad (HF). The detailed fabrication process and the metrology measurement results of these mirrors are introduced in this paper. Preliminary beamline test results showed that the mirror pair achieved the design goal [1].

8851-15, Session 4

Design optimization of ultra-precise elliptical mirrors for hard x-ray nanofocusing at Nanoscopium

Cameron M. Kewish, François A. Polack, Synchrotron SOLEIL (France); Riccardo Signorato, Bruker ASC GmbH (Germany); Andrea Somogyi, Synchrotron SOLEIL (France)

The design and implementation of a pair of 100 mm-long grazing-incidence total-reflection mirrors for the hard X-ray beamline Nanoscopium [1] at Synchrotron Soleil is presented. A vertically and horizontally nanofocusing mirror pair, oriented in Kirkpatrick-Baez geometry have been designed and fabricated using deterministic polishing, with the aim of creating a diffraction-limited high-intensity 5-20 keV beam with a focal spot size as small as 50 nm (full-width at half-maximum, FWHM). We describe the design considerations, including wave-optical calculations [2] of figures-of-merit that are relevant for spectromicroscopy, including the focal spot size, depth of field and integrated intensity. The mechanical positioning tolerance in the pitch angle that is required to avoid introducing high-intensity features in the neighborhood of the focal spot is demonstrated with simulations to be of the order of microradians, becoming tighter for shorter focal lengths and therefore directly affecting all nanoprobe mirror systems. Metrology results for the completed mirrors are presented, showing that better than 2 Å-rms figure error over spatial frequency bandwidths from 100 µm to full substrate length (and in the sub-100µm regime better than 1 Å-rms) has been achieved, with respect to the designed elliptical surfaces, with less than 61 nrad-rms slope errors.

8851-16, Session 5

Focus characterization of multilayer Laue lens using phase retrieval

Xiaojing Huang, Hanfei Yan, Evgeny Nazaretski, Brookhaven National Lab. (United States); Ross Harder, Argonne National Lab. (United States); Ian Robinson, Univ. College London (United Kingdom); Kenneth Lauer, Dennis Kuhne, Yong S. Chu, Brookhaven National Lab. (United States)

It is of critical importance to quantitatively characterize the performance of X-ray optics, when advanced X-ray lenses can produce focal sizes to sub-10 nm range. Ptychography, a phase-retrieval based method, is capable to reconstruct the complex-valued wavefront of X-ray beam, thus provide precisely characterization of lenses. We designed and built a dedicated instrument for ptychographical measurement of Multilayer Laue Lens (MLL). The X-ray wavefront focused by a MLL with 43 micron aperture and 4.2 mm focal length was successfully reconstructed from experimental data. 12 nm line focus was obtained. This method will be matured as a characterization tool to examine MLL lenses fabricated under various conditions for the purpose of rational optimization of fabrication process.

8851-17, Session 5

Ronchi interferometry for characterization of nanofocusing hard x-ray optics

Ulrich Vogt, Fredrik Uhlen, Daniel Nilsson, Hans M. Hertz, Royal Institute of Technology (Sweden); Frank Seiboth, Technische Univ. Dresden (Germany); Andreas Schropp, SLAC National Accelerator Lab. (United States); Christian G. Schroer, Technische Univ. Dresden (Germany)

Hard x-ray nanobeams have become an important tool in modern synchrotron radiation research. These nanobeams are usually created by focusing undulator radiation with highly specialized nanofocusing optics like reflective Kirkpatrick-Beaz mirror systems, diffractive zone plates or refractive compound lenses to focal spot sizes below 100 nm in diameter. The optics should in the best case not introduce any aberrations into the wavefield to ensure diffraction-limited focusing performance, and therefore the characterization of the hard x-ray nanobeam behind the focusing optic has become an important issue. We have introduced a classical scheme for this task, the so-called Ronchi test. A periodic pattern, normally a grating, is placed close to the focal plane of an optical system, and a detector is placed at a certain distance behind. The different diffraction orders of the grating can then interfere with each other, giving rise to a characteristic fringe pattern that can be evaluated to obtain information about the quality of the wavefront. Although well-known from visible optical metrology, it has not been applied for hard x-ray radiation. We believe that this test could offer a number of advantages compared to existing methods for hard x-ray beam

characterization. We will present results from experiments with both diffractive and refractive nanofocusing optics and using synchrotron as well as free electron laser radiation. We will show that the Ronchi method is simple to implement and can, in the case of free electron laser, provide single-shot information about focusing quality.

8851-34, Session PWed

High-efficiency x-ray nanofocusing using the kinoform stacking of binary zone plates

Istvan Mohacsi, Christian David, Petri Karvinen, Ismo J. Vartiainen, Paul Scherrer Institut (Switzerland); Andrea Somogyi, Cameron M. Kewish, Pascal Mercère, Synchrotron SOLEIL (France); Ana Diaz, Paul Scherrer Institut (Switzerland)

The efficiency of binary Fresnel zone plate lens is limited by the fact that they have equally strong positive and negative diffraction orders. To surpass this limitation, a kinoform lens profile is required. The multi-step approximation of this profile can be achieved by several aligned layers of fabrication. This approach is very challenging for small zone width and high photon energies, where high zone structures are required. Here we demonstrate an alternative method by the stacking of two binary zone plates in each others near-field to produce an effective 4-step profile. By using a “coarse” zone plate with giving a π phase shift and a “fine” zone plate with double line density giving a $\pi/2$ phase shift, theoretical diffraction efficiency up to 71% can be obtained for nickel zone structures at 6.5 keV photon energy. This is almost twice the value of the corresponding binary zone plate. The approach has been verified using a compact experimental setup based on piezo actuators for fine alignment. For a zone plate pair with 500 µm diameter and 200 nm effective outermost zone widths, we measured a diffraction efficiency of 47.1%, which is clearly beyond the limitations of binary zone plates. This zone plate is meant to provide high intensity illumination for ptychographic experiments at the Nanoscopium beamline of the synchrotron SOLEIL.

8851-35, Session PWed

Recent developments in cryogenic synchrotron and laboratory x-ray microscopy

Benjamin Hornberger, Michael Feser, Claus Flachenecker, Jeff Gelb, Jeffrey Irwin, Xradia, Inc. (United States); Chris J. Jacobsen, Argonne National Lab. (United States); Andrei Tkachuk, Dave Trapp, Wenbing Yun, Xradia, Inc. (United States)

For specimens from the life sciences like cells and tissue, cryogenic sample handling is essential for limiting the effects of radiation damage and preservation of the sample structure when imaging at high resolution (tens of nanometers). We present here recent instrumentation developments and initial experimental results of a new suite of cryogenic x-ray microscopes.

A full-field microscope operating in the water window range (280 to 540 eV) has been developed for cryogenic tomographic imaging of individual cells or similar specimens. The microscope can operate at a synchrotron beamline as well as with a laboratory soft x-ray source. Tomographic images of frozen hydrated yeast at about 40 nm resolution, obtained with a nitrogen plasma laboratory source operating at 430 eV, will be presented. A hard x-ray version operating from 5 to 11 keV for imaging of tissue sections and other thicker specimens is currently in commissioning. Furthermore, a scanning nanoprobe has been developed for trace element mapping in frozen hydrated life science samples. It operates in the 5 to 20 keV energy range at a resolution down to 30 nm.

All instruments described here share a common cryogenic sample handling system based on cartridges that allow offline sample preparation with subsequent sample transfer into the microscope under cryogenic conditions and robotic sample exchange inside the microscope. The system further allows cryogenic sample transfer to other instruments like cryogenic light or electron microscopes for imaging of the same specimen with different methodologies, correlating for example structure and function.

8851-36, Session PWed

Development of a high-resolution imaging system at the Polish Synchrotron

Marian Cholewa, Politechnika Rzeszowska (Poland); Marek J. Stankiewicz, Jagiellonian Univ. in Krakow (Poland); Czeslaw Koziol, ELMITEC Elektronenmikroskopie GmbH (Germany)

This presentation will describe our work towards a new high resolution imaging system considered for the Polish Synchrotron SOLARIS in Krakow, Poland. The inspiration for this development derives from earlier research projects covering two fields:

A. Development of high resolution the photo electron emission microscopy (PEEM) systems where resolution down to 2 nm has been already achieved. To follow this direction it is necessary to develop and apply in the system a highly efficient materials for secondary electron emission (SEE).

B. Investigation of new materials with high SEE. The SEE yield of heterostructures of ZnO nanoneedles coaxially coated with AlN or GaN has been studied for the first time using electron, ion, and X-ray beams. The SEE yield of the heterostructures is enhanced significantly by the intrinsic nanostructure of the ZnO nanoneedle templates as compared to the AlN and GaN thin films on Si substrates.

Combination of these two projects will allow development of a high resolution imaging system (with resolution down to 50 nm) with reduced cost when compared with traditional X-ray imaging systems. A 300 nm spatial resolution has already been demonstrated by several groups. Details of the project will be presented at the conference.

Analysis of impact of sintering temperature on microstructure of LSCF-SDC composite cathodes using nano-CT

Yong Guan, Xin Pan, Gang Liu, Xiaobo Zhang, Ying Xiong, Yangchao Tian, Changrong Xia, Univ. of Science and Technology of China (China)

Composites of La0.4Sr0.6Co0.8Fe0.2O3Nd (LSCF) with samarium doped ceria (SDC) has been extensively used as cathodes for solid oxide fuel cells (SOFCs) to lower its operation temperature. The ability to visualize three-dimensional (3D) microstructural changes in LSCF-SDC composite cathodes caused by processing can help elucidate the impact of microstructure on cathode performance. This study reports that we utilize the nano-computed tomography (nano-CT) technique to image the 3D microstructures of La0.4Sr0.6Co0.2Fe0.8O3 (LSCF) - Ce0.8Sm0.2O1.9 (SDC) composite cathodes which were sintering at 800, 1000, and 1200°C, respectively, for 2 h based on the Fe K-absorption edge. Using the reconstructions of LSFC-SDC composite cathodes submitted to different temperatures, the key microstructural properties, such as volume fraction of each phase, connected volume fraction, surface area, triple-phase boundary length, and pore size were measured. The effect of sintering temperature on the microstructure of LSFC-SDC cathodes was discussed and compared with theoretical simulation. With increasing sintering temperature in the range from 800 to 1200oC LSFC-SDC composite cathode microstructure was found that the volume fraction and grain size of LSCF material increased, while the volume fraction of SDC decreased. Furthermore, the triple-phase boundary length per volume increased as the sintering temperature increasing, which is consistent with the theoretical simulation data from previous literature1. This study had revealed that the nano-CT can provide a powerful tool to investigate the 3D microstructure of energy materials and optimize its preparation condition to gain better functional performance.

Reconstruction of yeast cells imaging using algebraic reconstruction technique

Zhiting Liang, Yong Guan, Xiangxia Song, Rui Bian, Gang Liu, Xiaobo Zhang, Ying Xiong, Yangchao Tian, Univ. of Science and Technology of China (China)

Full-field hard X-ray tomography based on Fresnel zone-plates has been applied to obtain nanoscale internal-structures of biological samples. The imaging of the yeast based on Zernike phase contrast imaging technique and heavy metal staining method has better contrast than that based on absorption imaging. Generally, there are two key aspects influencing the sufficiency of projections of biological samples for precise image reconstruction. One is that the maximum rotation angle of the sample stage has been limited for yeast imaging. The other is that long time imaging may cause the serious environmental noise pollution which would reduce the quality of the projection image. In condition that the projection data is insufficient, Algebraic Reconstruction Technique (ART) is the better choice than Filtered Back Projection (FBP). The ART would obtain a better spatial resolution of the reconstructed image. It is also possible to incorporate some types of priori knowledge about the image into the solution to improve the robustness of the algorithm proposed and speed up the convergence. In this work we applied the ART to numerical demonstration and the reconstruction of yeast cells. Different parameters were used for the ART to obtain a better result. The results show ART is a suitable tool for reconstructing the insufficient projection data.

A LabVIEW-based nano-CT image alignment software platform

Shenghao Wang, Univ. of Science and Technology of China (China); Kai Zhang, Chinese Academy of Sciences (China); Zhao Wu, Zhili Wang, Kun Gao, Univ. of Science and Technology of China (China); Ziyu Wu, Univ. of Science and Technology of China (China) and Chinese Academy of Sciences (China)

As a uniquely non-destructive high resolution visualization tool, X-ray nanometer computed tomography (nano-CT) has been found wide application in scientific research and industrial area. However in practical experiment, because of the mechanical vibration and thermal expansion, the rotation axis of the sample room would always jitter during its rotating procedure, which would cause blurring and additional streaking artifacts in 3D reconstruction if without an accurate calibration of the center of rotation. Here based on National Instrument's Laboratory Virtual Instrumentation Engineering Workbench (LabVIEW), by means of gray value barycenter and circle fitting method, the gold particles acting as the reference point in each projective image would be automatically detected, after relevant adjustment in horizontal and vertical direction, almost no artifacts in latter 3D reconstruction exist. This nano-CT image alignment software platform dedicated for nano-CT equipment at Beijing Synchrotron Radiation Facility (BSRF) facilitates users during their experiments.

Quantitative data from in-line phase contrast: analytical phase-retrieval methods

Anna Burvall, Ulf Lundström, Daniel H. Larsson, Hans M. Hertz, Royal Institute of Technology (Sweden)

In-line phase-contrast x-ray imaging is a method readily used for obtaining phase information, but the generation of quantitative data requires phase retrieval. We identify and analyze the seven existing analytical approaches, and integrate those into a single method [1]. Each method is then presented as a variation of this unified method, and a scheme for choosing a relevant phase-retrieval method presented.

Using in-line phase-contrast imaging, edge-amplified images are obtained. The edges of a sample are clearly shown, and the images provide excellent data on, e.g., the presence or location of an object. But for quantitative data, such as the thickness of an object, and for tomographic reconstruction and surface rendering, the raw data must be processed to reconstruct the object. This procedure is phase retrieval, and can be done analytically or iteratively.

Concentrating on the analytical methods for speed and simplicity, and considering only the single-distance setup, we identify seven existing approaches, show that these methods all follow the same pattern, and present them as a unified method. The different approaches are separated by differences in specific steps of the methods. We also outline the assumptions and approximations of those approaches and from that information can provide a simple scheme for choosing the correct phase-retrieval approach in a specific situation. Examples of phase retrieval for biological or material samples are presented.

Conceptual design for the hard x-ray nanoprobe beamline at the SSRF

Aiguo Li, Hua Wang, Yan He, Hui Jiang, Chengwen Mao, Shanghai Institute of Applied Physics (China)

The hard X-ray nanoprobe beamline (HXN) planned at Shanghai Synchrotron Radiation facility (SSRF) will be of capability to realize a focal spot size of below 30 nm for hard X-rays to satisfy urgent requirements in material, biology, environment sciences and etc. The cryogenic permanent magnet undulators (CPMU18) will be selected and cover the energy range of 5-30 KeV. A plane mirror will be put in front of monochromator to decrease heat load and a toroidal mirror in front of secondary slit to realize pre-focusing. The beamline includes two modes of operation, high flux mode and high energy resolution mode respectively. High flux mode is based on a double multilayer monochromator (DMM) and a multilayer-based Kirkpatrick-Baez mirror system, which can obtain 4E+9 photons/s flux at the sample position at 15 KeV. A pair of Montel nested multilayer-based K-B mirror with Pt/C periodic structure can afford large numerical aperture and enough working space. By precise mechanical control and wavefront correction, it is possible for focusing beam to reach down to 30 nm and even to 10 nm. This mode will offer high flux for elemental mapping at low concentration. A double crystal monochromator (DCM) serves for high energy resolution mode to obtain energy resolution ($\Delta E/E$) of 2E-4. Multilayer Laue lens or transmission zone plate of large diameter is planned to focus X-rays to 30 nm with 4E+8 photons/s flux at the sample position at 10keV. The second mode will mainly be used for XANES and diffraction applications in nanoscale.

A soft x-ray beamline for quantitative nanotomography using ptychography

Grant A. van Riessen, La Trobe Univ. (Australia); Mark Junker, La Trobe Univ. (Australia) and ARC Ctr. of Excellence for Coherent X-Ray Science (Australia); Bruce Cowie, Australian Synchrotron (Australia); Andrew G. Peele, La Trobe Univ. (Australia) and Australian Synchtron (Australia)

Soft X-ray nanotomography using ptychographic coherent diffractive imaging allows quantitative imaging of the internal structure of biological and materials samples with high sensitivity. In this work, we describe the experimental development of soft X-ray nanotomography at the Australian Synchrotron. An undulator beamline provides a highly coherent X-ray beam of variable polarization over an energy range 200 to 2000 eV. Illumination of the sample with a divergent beam produced using a zone plate provides a pathway to improving X-ray dose efficiency and the reliability of recovering images from diffraction data. However, this demands nanometre stability between the sample and optics, which is achieved using an interferometric metrology system. Data from characterisation studies and recent experiments are presented to illustrate the potential for fast, highly dose efficient nanotomography.

Nanoparticle assembly local order characterization by angular correlation analysis of soft x-ray coherent scattering patterns

Konstantine Kaznatcheev, Brookhaven National Lab. (United States); David Shapiro, Lawrence Berkeley National Lab. (United States); Shengyu Wang, Fang Lu, Oleg Gang, Brookhaven National Lab. (United States)

Materials that lack long range translational order present a substantial difficulty for characterizing their “atomistic” structure. As a result, property-to-structure relation for glasses, gels, foams or colloidal crystals are not well established. Coherent x-ray scattering speckle pattern uniquely defines a spatial distribution of scatters and the recent development of coherent diffraction imaging (CDI) is meant to be a route for reconstruction of their spatial distribution. Unfortunately, even with the development of ptychography -- a robust image reconstruction technique not limited by isolated specimen requirement or a priori knowledge of incident illumination -- real experiments often fail, especially when only incomplete (with missing portion of Q space) or noisy data set are available. If one is primarily interested in symmetry of scatters local arrangement, a full CDI inversion is not needed and parameters of hidden structural ordering can be revealed by employing x-ray cross-correlation analysis (XCCA) directly to the speckle map (1). Smaller spot size (fewer effective scatters probed) help to divulge distinct angular correlation even for a disordered structures, where a raster scanning provide needed statistical averaging over the large ensemble. As XCCA is done on a point-by-point basis, the spatial distribution of particular structural motif can be mapped this way. Alternatively, one can measure a decrease of angular correlation XCCA as probe size increases (as in fluctuation microscopy (2)) to extract the spatial extent (correlation length) of distinct structural motifs for a given specimen point. Using a dense nano-particle 2D assembly, as a model system, we present and discuss experimental results stressing advantage and practical limitations of XCCA approach to accurate and systematic characterization of disorder systems.

Recent advances in use of atomic layer deposition and focused ion beams for fabrication of Fresnel zone plates for hard x-rays

Kahraman Keskinbora, Max-Planck Institut für Intelligente Systeme (Germany); Anna-Lena Robisch, Friedrich-Schiller-Univ. Jena (Germany); Corinne Grévent, Marcel Mayer, Max-Planck Institut für Intelligente Systeme (Germany); Adriana V. Szeghalmi, Friedrich-Schiller-Univ. Jena (Germany); Mato Knez, CIC nanoGUNE Consolider (Spain) and IKERBASQUE. Basque Foundation for Science (Spain); Markus Weigand, Max-Planck Institut für Intelligente Systeme (Germany); Anatoly A. Snigirev, Irina I. Snigireva, European Synchrotron Radiation Facility (France); Tim Salditt, Georg-August-Univ. Göttingen (Germany); Gisela Schütz, Max-Planck Institut für Intelligente Systeme (Germany)

Developments and advances in e-beam lithography (EBL) made it possible to reach resolutions in a single digit nanometer range in the soft x-ray microscopy using Fresnel Zone Plates. However, it is very difficult to fabricate efficient Fresnel zone plates for hard x-rays via this conventional fabrication technique due to limitations in the achievable aspect ratios. Alternative focusing methods such as MLL and K-B mirrors also showed remarkable advances, although 2-D imaging in the real space remains to be demonstrated . Recently, we have been working on a couple of alternative methods. In one method, we fabricate a multilayer type FZP via atomic layer deposition (ALD) followed by focused ion beam (FIB) machining. In this method a ML-FZP with very high aspect ratio can be fabricated from a wide variety of materials. We already demonstrated diffraction efficiencies up to >15 % at 8 keV as well as both direct and indirect estimation of resolutions down to 30 nm. Some future projections in terms of available materials and target resolutions regarding this method will be discussed. In an other approach, we demonstrated previously, that a FZP can be fabricated easily in a single step, via ion beam lithography (IBL). Such IBL-FZPs were already successfully employed in the soft X-ray range enabling higher order imaging. Here, we show and discuss how this new method may be extended to the fabrication of Fresnel zone plates for hard X-ray range.

Simplicity from complexity: Non-negative matrix analysis applied to x-ray spectromicroscopy

Rachel Mak, Northwestern Univ. (United States); Chris J. Jacobsen, Argonne National Lab. (United States) and Northwestern Univ. (United States); Mirna Lerotic, 2nd Look Consulting (Hong Kong, China); Holger Fleckenstein, Deutsches Elektronen-Synchrotron (Germany); Stefan Vogt, Argonne National Lab. (United States); Yefim Sheynkin, Stony Brook Univ. (United States)

In a sample containing mixed chemical states, it is important to be able to correctly identify the individual spectral components in order to characterize the chemical structure and composition of the sample, with applications such as environmental remediation and understanding biological complexes. Using data from x-ray spectromicroscopy, where an optical density (or transmission) spectrum is obtained at each pixel, principal component analysis can be used to reduce the dimensionality of the dataset and provide an orthogonal basis of abstract components which describes the variability in the data; these results can be complemented with cluster analysis to identify more realistic (rather than abstract) spectra.

However, given an optical density spectrum, which is a product of the absorption of each component and its corresponding thickness, the above methods may sometimes reconstruct negative thickness regions in the sample. To eliminate this non-physical result, we employ the method of non-negative matrix approximation (NNMA), which imposes a non-negative constraint on the reconstructed spectra and thicknesses. NNMA takes two initially random factor matrices, representing the component spectra and their thicknesses respectively, and uses iterative gradient descent until their product converge with the observed optical density within some set tolerance measured by the minimization of a cost function. Additional constraints may be added to the cost function, such as imposing smoothness to improve spectra reconstruction. It can also be shown that correctly constraining the sparseness of the thickness matrix can lead to an improvement in the speed and quality, as well as accuracy, of the spectra reconstruction.

Parallel high-resolution x-ray imaging

Konstantine Kaznatcheev, Brookhaven National Lab. (United States); Jian Wang, Canadian Light Source Inc. (Canada) and Univ. of Saskatchewan (Canada); Weilun Chao, Eric H. Anderson, Lawrence Berkeley National Lab. (United States)

Many x-ray optical element (refractive, as compound refractive and kinoform lenses or diffractive - zone plates) that pushed imaging below 100nm spatial resolution is produced using microfabrication technology and their production can be scaled from single element to a fabrication of x-ray optical array. When combined with 2D x-ray detection, such approach leads to a development of novel concept of x-ray imaging, particular useful for measurements of extended objects, such as medical and biological specimens or industrial components (MEMS devices, ??) on conventional x-ray sources at spatial resolution previously not achieved. Following we report first measurements using x4 ZP array on a scanning x-ray microscope outfitted with x-ray CCD and discuss advantages and limitations of x-ray parallel imaging.

Endstation development for the HXN nanoprobe at the NSLS-II

Evgeny Nazaretski, Brian Mullany, Hanfei Yan, Kenneth Lauer, Kazimierz J. Gofron, Dennis Kuhne, Xiaojing Huang, Sebastian Kalbfleisch, Brookhaven National Lab. (United States); Deming Shu, Argonne National Lab. (United States); Yong S. Chu, Brookhaven National Lab. (United States)

In this work we present our approach to develop a scanning microscope for x-ray imaging in the hard x-ray regime. We implement two types of nanofocusing optics e.g. Fresnel zoneplates and Multilayer Laue Lenses to achieve nanoscale imaging. Fresnel zoneplates will enable imaging with the spatial resolution down to 30 nm and Multilayer Laue Lenses will be used to perform nanofocusing down to 10 nm respectively. Two individual modules will accommodate different types of nanofocusing optics; they can be moved and swapped inside the vacuum chamber without interference. In addition, temperature regulation of the sample in the range between 85 and 1000 K will enable phase transition studies in materials science and condensed matter physics experiments. Novel approach which includes modular design, state-of-the-art fiber optic interferometry and compact, high stiffness piezo-based positioners will be discussed. Extensive R&D work has been performed to thoroughly evaluate and characterize individual components integrated into a microscope. We present preliminary results for resolution, thermal stability and vibrations characteristics for the prototype module equipped with the Multilayer Laue Lenses. Sub-nm sensing resolution, nm-size stepping and drifts less than 4nm/hour have been demonstrated.

Full-field x-ray nano-imaging at SSRF

Biao Deng, Yuqi Ren, Yudan Wang, Guohao Du, Honglan Xie, Tiqiao Xiao, Shanghai Institute of Applied Physics (China)

A new full field X-ray nano-imaging beamline based at a bending magnet source is included in the SSRF phase-II project. The beamline aims at 3D nano-imaging of nanoscale inner structures. The photon energy range is of 5-14 keV. The design goals of FOV of 20 µm and spatial resolution of 20 nm are proposed at 8 keV with 25 nm FZP outermost zone width. The beamline is composed of, a parabolic cylindrical mirror, a toroidal mirror, double crystal monochromator with 2 sets of crystals for on-line exchange: standard Si (111) crystals and asymmetrically cut crystals. We propose to use asymmetrically cut crystals to regain most of the flux at an acceptable increase in bandwidth. In addition, an X-ray nano-imaging microscope is under developing at SSRF BL13W beamline, in which large field of view will be imaged and the spatial resolution is set to sub 100nm. This microscope is based on beam shaper [1] and zone plate using absorption contrast and zernike phase contrast, with the optimized energy set to 10keV. The detailed design and the progress of the project will be introduced.

8851-18, Session 6

Development of synchrotron-radiation-based low-temperature scanning tunneling microscopy (SXSTM) *(Invited Paper)*

Nozomi Shirato, Argonne National Lab. (United States); Heath Kersell, Saw Wai Hla, Ohio Univ. (United States); Marvin Cummings, Curt A. Preissner, Volker Rose, Argonne National Lab. (United States)

High resolution scanning tunneling microscopy (STM) combined with synchrotron X-rays provide an exciting scientific tool to explore surface science. Synchrotron x-ray scanning tunneling microscope (SXSTM), is capable of probing not only topographic and electronic properties but also elemental uniqueness and magnetic states of surfaces from mesoscopic lengths down toward the atomic level. The underlying fundamental mechanism is that the inner-shell electron excitation at a specific level by X-rays can be locally probed by the STM tip, and it allows us to identify chemical and magnetic signals with high spatial resolution. Here we will discuss the ongoing development of a next-generation SXSTM featuring low temperature and high resolution STM with X-ray radiation. The project is based on a prototype instrument that has been developed in our group. Some additional features are incorporated with the new system. For instance, the new compactly designed STM utilizes a flow cryostat to cool the microscope. It helps to meet overall size limitation of an instrument at a synchrotron beamline. The microscope is supported by a three-axis translation and a single axis rotation stage to facilitate the alignment of the tip and sample with respect to the incoming X-ray beam. The challenges and unique opportunities of developing the system will also be discussed.

8851-19, Session 6

Development of an in-vacuum x-ray microscope with cryogenic sample cooling for beamline P11 at PETRA III

Alke F. Meents, Bernd Reime, Nicolas Stuebe, Pontus Fischer, Martin Warmer, Dennis Goeries, Jan Roever, Jan Meyer, DESY (Germany); Ismo J. Vartiainen, Christian David, Paul Scherrer Institut (Switzerland)

Beamline P11 at PETRA III is dedicated to structural investigations of biological samples. In provides two experimental stations, one for macromolecular crystallography and one for X-ray microscopy. The microscope will provide full field Zernike phase contrast and scanning microscopy both in 2D and in tomographic mode. Full field microscopy with a field of view of 50 x 50 µm2 will allow to generate an overview of the sample and to select regions of interest for later inspection of the element distribution by X-ray fluorescence in scanning mode.

Central part of the microscope is an inhouse developed flexure based x,y,z scanner on top of a rotation stage. The scanner is operated in closed loop with piezo motors, has a travel range of 4 mm in horizontal and of 3 mm in vertical direction. With laser interferrometers for closed loop operation a positioning accuracy of better than 5 nm is achieved in all directions. For precise sample rotation an in-vacuum air-bearing has been developed. An open bore in the center of the air-bearing will allow for cryogenic sample cooling by a cold He or N2 gas stream.

Different optical elements such as beam defining pinholes, a condensor, zone plates, OSA, phase rings, etc. can be centered in the beam path by piezomotoer driven x,y flexure elements mounted on a rail system which allows further positiong along the beam path. Different 2D detectors and two fluoresence detectors can be attached to the microscope.

The microscope design and first results will be presented.

8851-20, Session 6

NanoMAX: a hard x-ray nanoprobe beamline at MAX IV

Ulf Johansson, MAX IV Lab. (Sweden); Ulrich Vogt, Royal Institute of Technology (Sweden); Anders Mikkelsen, Lund Univ. (Sweden)

NanoMAX is the name of the first x-ray imaging beamline at the new Swedish synchrotron radiation source MAX IV. It is a hard X-ray undulator beamline for micro- and nanobeams and will enable imaging applications exploring diffraction, scattering and fluorescence methods. A major consideration for the construction of NanoMAX is to utilize MAX IV's exceptional low emittance, high brilliance and coherence properties of the x-ray beam. This should make the NanoMAX beamline a flagship beamline for MAX IV showcasing the full potential of the ring.

NanoMAX aims for a final resolution goal of 10 nm while keeping the option of flexible beam sizes up to about 1 um providing the possibility of matching spot size and divergence to the experimental requirements. The beamline will feature two endstations: One with beamsizes down to 300 nm, extremely well suited for scattering and coherence experiments in very flexible sample environments. A second endstation will make it possible to reach the highest resolution with the options of doing diffraction and fluorescence experiments on very small nanoscale objects.

The technical design of the beamline will be presented, including details on beamline optics layout and simulations, undulator parameters and experimental station equipment. The design of the dedicated experimental station building and other infrastructure will also be described.

The NanoMAX beamline project got funded late 2011 and the beamline is planned to open to users late 2016.

8851-21, Session 6

A dedicated hard x-ray diffraction nanoprobe beamline for materials studies at APS

Zhonghou Cai, Wenjun Liu, Jonathan Z. Tischler, Ruqing Xu, Deming Shu, Oliver Schmidt, Argonne National Lab. (United States)

Aiming at studies of the micro/nanostructures of a broad range materials and electronic devices, Advance Photon Source (APS) is developing a diffraction nanoprobe beamline for the needs arising from a multidiscipline research community. The planed facility integrates the K-B mirror based polychromatic Laue diffraction and the Fresnel zone-plate based monochromatic diffraction techniques that currently support 3D/2D microdiffraction programs at the 34-ID-E and 2-ID-D of the APS, respectively, and both are designed to have a 50-nm or better special resolution. As a part of the APS Upgrade Project, the nanoprobe beamline has been preliminarily designed and will be constructed at the sector 34-ID. The nanoprobe facility uses an APS-3.0-cm period undulator, a liquid-nitrogen cooled mirror as its first optics, and a water cooled small gap silicon double-crystal monochromator of an energy range of 5-30 keV. The ultra-precision focusing mirror with low figure error and surface roughness and a set of zone plates have been designed to optimize for focusing efficiency and the working distance based on the attainable beamline length and the beam coherence. To ensure the nanoprobe performance, high stiffness and high precision flexure stage systems have been designed for optics mounting and sample scanning, and high precision temperature control of the experimental station will be implemented to reduce thermal instability. Designed nanoprobe beamline has a good management on thermal power loading on optical components and allows high degree of the preservation of beam brilliance for high focal flux and coherence. Integrated with variety of X-ray techniques, planed facility provides nano-XRD capability with the maximum reciprocal space accessibility and allows micro/nano-spectroscopy studies with K-edge electron binding energies of most elements down to Vanadium in the periodic table. We will discuss the preliminary design of the diffraction nanoprobe beamline and its technical relevance to a broad range of scientific applications.

8851-22, Session 6

Data analysis for x-ray fluorescence microscopy: unique challenges and opportunities

Stefan Vogt, Siwei Wang, Jesse Ward, Stefan Wild, Argonne National Lab. (United States); Martin D. de Jonge, Australian Synchrotron (Australia); Barry Lai, Sven Leyffer, Chris J. Jacobsen, Argonne National Lab. (United States)

X-ray fluorescence microscopy (XFM) is a powerful technique to map and quantify trace element distributions in biological specimens. It is perfectly placed to map nanoparticles and nanovectors within cells, at high spatial resolution. Advances in instrumentation, such as faster detectors, better optics, and improved data acquisition strategies are fundamentally changing the way experiments can be carried out, giving us the ability to more completely interrogate samples, at higher spatial resolution, higher throughput and better sensitivity. We have also developed software tools such as 'MAPS', that enable routine data processing of XFM datasets, including per-pixel fitting of full spectra and quantification of acquired elemental maps, principle component as well as cluster analysis.

Yet one thing is still missing: the next generation of data analysis and visualization tools for multidimensional microscopy that can interpret data, identify and classify objects within datasets, visualize trends across datasets and instruments, and ultimately enable researchers to reason with abstraction of data instead of just with images. We will report on the software tools for X-ray fluorescence microscopy at the APS, including on the latest developments. For example, we will demonstrate automated analysis by locating cells positions in a complex XFM dataset via image segmentation, determining exact cell regions via models of elemental content and cell shape, accounting for overlapping structures, and successfully distinguishing different cell types.

We will also identify unique challenges and opportunities brought about by instrumentation advances, and discuss steps we have taken to exploit these opportunities through advances in data analysis.

8851-23, Session 7

CSI using XFM: chemical state imaging using fast x-ray fluorescence microscopy

David J. Paterson, Martin D. de Jonge, Daryl L. Howard, Kathryn Spiers, Australian Synchrotron (Australia); Chris G. Ryan, Robin Kirkham, Commonwealth Scientific and Industrial Research Organisation (Australia)

X-ray fluorescence microscopy (XFM) can be used for elemental and chemical microanalysis across length scales from the millimeter to the nanometer. Advances in X-ray fluorescence detection schemes such as the Maia detector now enable high definition images at mega-pixel per hour rates. Fast XFM also enables 3D scans such as fluorescence tomography to be acquired in realistic times. Chemical speciation (valence) imaging (CSI) is a 3D technique where the third dimension becomes incident energy producing an X-ray Absorption Near Edge Structure spectra at each pixel. Recent examples of CSI at the Australian XFM beamline will be presented.

8851-24, Session 7

Simultaneous fast scanning XRF, dark field, phase-, and absorption contrast tomography

Kadda Medjoubi, Nicolas Leclercq, Florent Langlois, Pascal Mercère, Andrea Somogyi, Synchrotron SOLEIL (France)

Hard X-ray nanoprobe imaging provides a unique tool for probing specimens with high sensitivity and large penetration depth. Moreover, the combination of complementary techniques such as X-ray fluorescence, absorption, phase contrast and dark field imaging gives complete quantitative information about the sample structure, composition and chemistry.

The multi-technique fast “Flyscan” data acquisition scheme developed at Synchrotron SOLEIL [1] makes scanning tomography techniques feasible in a time-frame well-adapted to typical user experiments. Here we present the recent results of simultaneous fast scanning multi-technique tomography performed at Soleil. This fast scanning scheme will be implemented at the Nanoscopium beamline for large field of view 2D and 3D multimodal scanning imaging.

8851-25, Session 7

The Maia detector array and x-ray fluorescence imaging system

Chris G. Ryan, Commonwealth Scientific and Industrial Research Organisation (Australia); David P. Siddons, Brookhaven National Lab. (United States); Robin Kirkham, Commonwealth Scientific and Industrial Research Organisation (Australia); Zhi Yong Li, Brookhaven National Lab. (United States); Martin D. de Jonge, David J. Paterson, Australian Synchrotron (Australia); James S. Cleverley, Commonwealth Scientific and Industrial Research Organisation (Australia); Anthony J. Kuczewski, Brookhaven National Lab. (United States); Paul A. Dunn, Murray Jensen, Commonwealth Scientific and Industrial Research Organisation (Australia); Gianluigi De Geronimo, Brookhaven National Lab. (United States); Daryl L. Howard, Australian Synchrotron (Australia); Gareth F. Moorhead, Commonwealth Scientific and Industrial Research Organisation (Australia); Simon A. James, Kathryn Spiers, Australian Synchrotron (Australia); Gerald Falkenberg, Gerd Wellenreuther, Ulrike Boesenberg, DESY (Germany); Stacey Borg, Commonwealth Scientific and Industrial Research Organisation (Australia)

X-ray fluorescence images collected using the Maia detector array and integrated real-time processor [1] on the X-ray Fluorescence Microscopy (XFM) beamline at the Australian Synchrotron [2] capture fine detail in element images up to ~100M pixels. Maia combines a large solid-angle annular energy-dispersive 384 detector array, stage encoder and flux counter inputs and dedicated FPGA-based real-time event processor enabling high definition imaging and enhanced sensitivity to capture the complex hierarchical detail in natural samples and detect rare trace structures and place them in a detailed spatial context. Methods have been developed for the real-time display of deconvoluted SXRF element images and for the acquisition of 3D data-sets for fluorescence tomography and chemical state (XANES) imaging.

This paper describes recent refinements in Maia hardware performance, methods for per pixel correction for pixel dwell and beam flux variation aimed at high quality images, methods for efficient processing of XANES image stacks, quantitative on-line images and off-line parallel processing methods for enhanced throughput, illustrated using complex geological, environmental and biological sample high definition data-sets acquired at the XFM beamline and recent data collected on the Hard X-ray Micro/Nanoprobe beamline P06 HASYLAB at DESY [3].

Ultrafast pulse processing electronics for high-flux florescence microscopy

Paul A. Scoullar, Southern Innovation (Australia); Peter M. Grudberg, XIA LLC (United States)

Many applications of florescence microscopy are severely limited by detector dead time. Historically, analogue pulse shaping was used to analyze detector output, however, digital pulse processing has been recognized as having advantages including: robustness against noise; and extended operational count rate range. We present a novel approach to detector pulse processing utilizing model based signal processing techniques and accurate parameter estimation. Using these techniques pile-up can be decomposed into the individual component events in real-time. By decoding pulse pile-up on the fly, little data is rejected resulting in a dramatic improvement in throughput without the traditional loss of energy resolution.

8851-27, Session 8

Hard x-ray scanning microscopy with coherent radiation: beyond the resolution of conventional x-ray microscopes *(Invited Paper)*

Christian G. Schroer, Technische Univ. Dresden (Germany); Andreas Schropp, Technische Univ. Dresden (Germany) and SLAC National Accelerator Lab. (United States); Robert Hoppe, Jens Patommel, Dirk Samberg, Frank Seiboth, Sandra Stephan, Technische Univ. Dresden (Germany); Gerd Wellenreuther, Gerald Falkenberg, DESY (Germany)

Based on nanofocusing refractive x-ray lenses we have built a hard x-ray scanning microscope at the synchrotron radiation source PETRA III at DESY in Hamburg. This instrument can make use of conventional x-ray analytical techniques, such as x-ray fluorescence, absorption, and diffraction in order to image an object with elemental, chemical, or nano structural contrast, respectively. In addition, it is optimized for coherent x-ray diffraction imaging techniques. We demonstrate x-ray scanning coherent diffraction microscopy (ptychography) with 10 nm

spatial resolution, clearly exceeding the resolution limits of conventional hard x-ray microscopy. The spatial resolution in a ptychogram is shown to depend on the shape (structure factor) of a feature and can vary for different features in the object. In addition, the resolution and contrast is shown to increase with increasing coherent fluence. For an optimal ptychographic x-ray microscope this implies a source with highest possible brilliance and ultimately an x-ray optic with a large numerical aperture to generate the optimal probe beam. The current limitations and future opportunities are discussed.

8851-28, Session 8

Coherent diffraction imaging of a complex sample with partially coherent source

Bo Chen, Brian Abbey, Mark Junker, La Trobe Univ. (Australia); Harry M. Quiney, The Univ. of Melbourne (Australia); Alberto Cereser, Mac Luu, Grant A. van Riessen, Keith A. Nugent, La Trobe Univ. (Australia)

Coherent Diffraction Imaging (CDI) is an important imaging method to look at the sample with the resolution of tens to several nanometers. With the development of modern X-ray source such as third-generation synchrotron and X-ray Free Electron Laser(XFEL), it is now possible to observe the inside structure or even molecular interaction in the sample without the need of section like traditional scanning electron microscopy (SEM). This is very important for a situ imaging. Because of the potential of its application in sciences, CDI has been used widely in material and biological sample since its first demonstration in experiment.

Although CDI has shown particular promise in applications involving X-ray free electron lasers and third generation synchrotron, the limited coherent output of these sources is the barrier to its application in practice. To get a successful data in traditional CDI experiment, the source is usually monochromated and spatially filtered so that the sample is illuminated with a highly coherent source. By doing this way, the most concerned issue is the loss of the flux. Due to the decrease of flux, the exposure time is usually much longer than 1s for every shot, thus the requirement to the stability of the experimental system is high. And it will prevent scientist from investigating the sample in real time. The problem can be solved by using a polychromatic source in the experiment. This was first realized in high-harmonic generation (HHG) imaging by using all harmonics in the experiment. Recently, a new CDI method with broadband beam ("polyCDI") has been demonstrated. In polyCDI, the source is considered as the combination of many monochromatic coherent modes with different frequencies. This requires that the spatial coherence of the source should still be high. For a real source, however, the coherent length is not always necessarily longer than the sample. So most likely, the sample is illuminated with a partially coherent source, which will blur the diffraction pattern thus decrease the resolution of the reconstruction. When the blur is serious, it is proved that the traditional CDI algorithm will fail and a partial CDI (PCDI) algorithm is needed for a good reconstruction .

In this presentation, we demonstrated that it is possible to include both spatially partial and temporally partial coherence in CDI reconstruction (pink PCDI) for a complex sample. We also analyzed the limit of the coherence length and bandwidth to this method.

8851-29, Session 8

Simultaneous x-ray fluorescence and ptychographic microscopy

David J. Vine, Argonne National Lab. (United States)

Combining X-ray fluorescence microscopy with ptychography is powerful because the contrast mechanisms of the two techniques are complementary. The X-ray fluorescence signal is sensitive to the elemental composition whereas ptychography, which images the complex transmission function, is sensitive to the electron density. Progress toward implementing ptychography at scanning X-ray fluorescence beamlines at the APS will be described as well as recent results.

8851-30, Session 8

Development of coherent x-ray zoom condenser lens for diffractive and scanning imaging

Takashi Kimura, Hokkaido Univ. (Japan); Satoshi Matsuyama, Hiroki Nakamori, Takumi Goto, Yasuhisa Sano, Osaka Univ. (Japan); Tetsuya Ishikawa, RIKEN (Japan); Yoshinori Nishino, Hokkaido Univ. (Japan); Kazuto Yamauchi, Osaka Univ. (Japan)

In this presentation, we propose a new optical system which adds a zooming function to x-ray diffraction microscope by controlling the x-ray beam size of coherent illumination. We propose two-stage deformable Kirkpatrick-Baez (KB) mirror optics to keep diffraction-limited focusing condition, ideal for x-ray diffraction microscope, with varying beam sizes. By extending our previous studies [1] to use deformable mirrors to compensate the figure error of condenser mirrors, we control the numerical aperture of condenser mirrors.

The proposed two-stage deformable KB mirror optics is designed to keep the focal length. It realizes diffraction-limited focused beam with variable sizes at a fixed sample position, as we confirmed by wave-optical simulation. This feature considerably simplifies microscope instruments and one can more easily zoom up regions of interest in sample in x-ray diffraction microscopy measurement.

We also propose a new image-reconstruction algorithm for extended objects from a single diffraction pattern by using the two-stage deformable KB mirror optics. The optics has two focal points, and one can create a spatially confined illumination by adequately putting a spatial filter at the first focal point. With this illumination, an extended sample can be regarded as isolated object, and sample images can be reconstructed without ptychographic procedures.

8851-31, Session 9

Optimized cavity-enhanced x-ray sources for x-ray microscopy *(Invited Paper)*

John M. Madey, Eric B. Szarmes, Michael Hadmack, Jeremy Kowalczyk, Univ. of Hawai'i (United States)

Assuming an electron beam emittance small in comparison to the wavelength of the colliding IR or optical photons, it can be shown that the total average power radiated by an inverse Compton light source with optimally focussed colliding electron and optical beams scales simply as the product of the instantaneous peak optical power and average electron current of the colliding optical and electron bunches. The principal challenge in designing such a source is therefore to find the combination of optical and accelerator technologies that can maximize this product at the desired final state photon energy subject to the constraints imposed by the limits on the peak power of the colliding optical pulses, the limits set by optical damage and thermal expansion of the optics for the system, and the available ebeam accelerator technology. A substantial enhancement in the radiated power at x-ray wavelengths can be attained in principal through the use of a high finesse optical storage cavity to integrate the output of a lower power phase. coherent pump laser. But it is generally impossible to achieve the required performance using a simple two-mirror resonator. We will describe a project at the University of Hawai'i to demonstrate the optical and accelerator technology needed to operate such an optimized high performance X-ray source at photon energies from 10-20 keV.

8851-32, Session 9

Establishing nanoscale laboratory hard x-ray microscopy in the Central Microscopy Laboratory

Michael Feser, Xradia, Inc. (United States)

3-D X-ray Microscopes with sub-50nm spatial resolution are establishing themselves in the central microscopy laboratory alongside optical and particle based microscopy techniques. Advances in x-ray optics, instrumentation, automation and algorithms have made these type of microscopes attractive to complement established microscopy tool sets. The ability to perform repeated non-destructive 3-D scans of larger samples and hierarchically focusing in on features of interest make x-ray microscopes an indispensable tool for 4-D (time, evolution) studies before preparing the sample for a destructive (FIB/e-beam) microscopy technique. Current performance, application and correlative workflow examples are presented.

8851-33, Session 9

Tabletop coherent diffractive imaging of extended objects in transmission and reflection geometry

Matthew D. Seaberg, Bosheng Zhang, Daniel E. Adams, Dennis F. Gardner Jr., Henry C. Kapteyn, Margaret M. Murnane, Univ. of Colorado at Boulder (United States)

Recent breakthroughs in high harmonic generation have extended the reach of bright tabletop coherent light sources from a previous limit of ≈100eV, in the extreme ultraviolet (EUV), all the way beyond 1keV in the soft X-ray region. Due to its intrinsically short pulse duration and spatial coherence, this light source can be used to probe physical processes at the femtosecond timescale, with nanometer-scale spatial resolution using a technique called coherent diffractive imaging (CDI).

CDI is an aberration-free technique that replaces image-forming optics with a computer phase retrieval algorithm, which recovers the phase of a measured diffraction amplitude. This technique typically requires the sample of interest to be isolated; however, it is possible to relax this constraint by imposing this requirement on the illumination. One such modification to the technique has been termed keyhole CDI, in which a hard edge is placed on the beam on its way to the focus.

Here we extend previous tabletop results, in which we demonstrated the ability to image a test object with 22nm resolution with 13nm light, to imaging of more complex samples using the keyhole technique adapted to our source. We have recently demonstrated the ability to image extended objects in a transmission geometry with ≈100nm resolution. Finally, we have taken preliminary CDI measurements of extended nanosystems in reflection geometry. We expect that this capability will soon allow us to image dynamic processes in nanosystems at the femtosecond and nanometer scale.

Conference 8852: Hard X-Ray, Gamma-Ray, and Neutron Detector Physics XV

Monday - Wednesday 26–28 August 2013

Part of Proceedings of SPIE Vol. 8852 Hard X-Ray, Gamma-Ray, and Neutron Detector Physics XV

8852-1, Session 1

Physics of scintillator light yield nonproportionality *(Invited Paper)*

Stephen A. Payne, Nerine J. Cherepy, Steven L. Hunter, Lawrence Ahle, Lawrence Livermore National Lab. (United States); Gregory A. Bizarri, William W. Moses, Lawrence Berkeley National Lab. (United States)

This presentation is on our work in elucidating the physics of light yield nonproportionality in scintillators. We have recently recorded the temperature dependence of the nonproportionality curves for doped CsI and NaI, and for several oxides; we have interpreted the results in terms of the impact on the migration of excitons. We have also studied a large number of Cerium-doped garnet-structure materials, and observed the impact of both composition and defects on the nonproportionality. We will summarize our experimental and modeled results on a large variety of different halide and oxide hosts, and finally describe the (expected) differences in the energy resolution and light yields characteristic of gammas versus electrons due to Compton scattering and the distribution of electrons created by photoelectric absorption.

Acknowledgements: This work was performed under the auspices of the U.S. DOE by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344, and has been supported by the US Department of Energy, Office of Nonproliferation Research and Development.

8852-2, Session 1

Time-encoded imaging of energetic radiation

Erik Brubaker, James Brennan, Peter Marleau, Kyle McMillan, Aaron Nowack, Nathalie Renard-Le Galloudec, Patricia Schuster, Sandia National Labs. (United States)

Time-encoded imaging (TEI) is a new approach to directional detection of energetic radiation that produces images by inducing a time-dependent modulation of detected particles. TEI-based detectors use single-scatter events and have a low channel count, reducing complexity and cost while maintaining high efficiency with respect to other radiation imaging techniques such as double-scatter or coded aperture imaging. The scalability of TEI systems makes them a very promising detector class for weak source detection. Extension of the technique to high-resolution imaging is also under study.

Experimentally, we have focused on fast neutron detection and imaging using TEI. Briefly, in time-encoded neutron imaging, a time modulation of a detected neutron signal is induced—for example, a moving mask that attenuates neutrons with a time structure that depends on the source position. Time-encoded imaging is in many ways analogous to coded aperture imaging; the spatial modulation of a particle flux induced by a fixed mask on a position-sensitive image plane is replaced by the time modulation of a particle flux induced by a moving mask on one or a few time-sensitive detectors.

With a prototype time-encoding detector, we demonstrated detection of a neutron source at 60 m with neutron output equivalent to an IAEA significant quantity of WGPu. We have since designed and built a full-scale detector based on the time-encoding concept. We will present results from characterization of very large liquid scintillator cells, including pulse shape discrimination, as well as from studies of the detector system performance in weak source detection scenarios.

8852-3, Session 1

Theoretical investigation of potential low-band gap scintillators

David J. Singh, Mao-Hua Du, Oak Ridge National Lab. (United States)

Most well developed scintillators for spectroscopic gamma detection have emission energies compatible with photomultiplier tubes. However, alternate light detection components, such as silicon photodiodes, allow for the use of lower emission energy scintillators. This is enabling for lower band gap scintillators which may potentially have higher light yield, and ultimate energy resolutions better than conventional materials. Here we present results from theoretical studies of lower band gap heavy halide materials and their activation to form new scintillator materials.

8852-4, Session 1

First-principles study of electronic structure, defects, and activators in LiCaAlF6

Mao-Hua Du, David J. Singh, Oak Ridge National Lab. (United States)

LiCaAlF6 (LiCAF) is a promising inorganic neutron scintillator material. Here, we report the electronic structure as well as properties of the small hole polaron, F center, and activators (e.g., Ce) in LiCAF based on first-principles calculations. These results are discussed in the context of carrier transport and trapping in LiCAF. We also discuss the approach to reduce reabsorption of Ce emission by the F centers, thereby suppressing afterglow in LiCAF:Ce after exposure to X- or gamma-ray.

8852-5, Session 2

Performance of 3D position-sensitive CdZnTe pixelated detectors *(Invited Paper)*

Aleksey E. Bolotnikov, Giuseppe S. Camarda, Yonggang Cui, Brookhaven National Lab. (United States); Václav Dedic, Charles Univ. in Prague (Czech Republic); Gianluigi De Geronimo, Jack Fried, Matthew Marshall, Brookhaven National Lab. (United States); Kisung Lee, Korea Univ. (Korea, Republic of); Utpal N. Roy, Matthew Petryk, Emerson Vernon, Ge Yang, Ralph B. James, Brookhaven National Lab. (United States)

We will describe the effects of the pixel geometry, readout electronics, and crystal defects on the performance of CdZnTe (CZT) pixelated detectors. The presented results provide insight into important details about the performance of CZT pixelated detectors and the relationship to pixel dimensions and crystal quality.

8852-6, Session 2

Drift time dependent CPG pulse height correction

Christian Disch, Alex Fauler, Andreas Zwerger, Freiburger Materialforschungszentrum (Germany); Markus Dambacher, X-RAY IMAGING EUROPE GmbH (Germany); Michael Fiederle, Freiburger Materialforschungszentrum (Germany)

High detector efficiency, especially at high photon energies, requires thick

detectors with large absorption. However, thick detectors with planar contacts usually show a strong correlation between pulse shape/height and interaction depth, causing low energy tailing and degraded energy resolution. Several different approaches circumvent this problem:

A) Low temperature detectors, e.g. LN2 cooled Germanium, with increased charge carrier lifetime and minimized charge carrier loss;

B) Coplanar Grid (CPG) detectors based on (Cd,Zn)Te, using a special anode configuration and subtraction of anode signals in order to remove nearly all hole contribution from the resulting signal;

C) Pixelated detectors, which effectively count the number of electrons reaching each anode pixel.

While low temperature detectors require constant and expensive cooling, and pixelated detectors demand complex read-out electronics, CPG detectors offer good compromise if one is only interested in energy information coupled with cheap room-temperature detector material and simple read-out electronics.

It has been shown, that multi-hit events degrade the energy resolution of detectors. Identifying and suppressing or correcting these events can increase detector performance. We will introduce a new method that uses hole drift times to correct standard CPG anode signals for interaction-depth dependent charge loss in case of multi- and single-hit events. 7 mm thick material is used with a CPG anode structure and modified cathode contact, enabling the precise measurement of drift times and subsequent correction of electron signals. Energy spectra with and without correction are presented, as well as a discussion of theoretical and actual improvements.

8852-7, Session 2

Etch-pit analysis of Cd(Zn,Mn)Te crystals grown by different methods

Anwar Hossain, Aleksey E. Bolotnikov, Giuseppe S. Camarda, Yonggang Cui, Genda Gu, Utpal N. Roy, Ge Yang, Ralph B. James, Brookhaven National Lab. (United States)

We evaluated the etch-pit distribution on the surface of cadmium zinc telluride (CZT) and cadmium manganese telluride (CMT) crystals grown by high-pressure Bridgman (HPB), travelling heater method (THM) and floating zone (FZ) method. Etch pits have been revealed on the crystals' surfaces by using different chemical etchants (e.g., Nakagawa, EAg with different silver concentrations, and Saucedo solutions). We have analyzed the pits' geometry, sizes, and densities to correlate them with the nature of the crystal's defects. We evaluated the areal densities and distributions of the etch pits associated with dislocations and other crystallographic defects using IR transmission microscopy and a scanning electron microscopy (SEM) combined with energy-dispersive x-ray spectroscopy (EDS). Results of these studies will be presented.

8852-8, Session 2

Atomic and electronic structure of dislocations in CdTe

Daniel Aberg, Vincenzo Lordi, Lawrence Livermore National Lab. (United States)

Cadmium telluride (CdTe) and related alloys such as CdZnTe are leading candidates for high energy-resolution, room-temperature semiconductor gamma and X-ray radiation detectors. Present limitations in performance are mainly due to defects found in large melt-grown crystals. Such defects range in scale from point defects to dislocations to twins and grain boundaries. These defects degrade detector performance primarily by reducing carrier lifetimes in the material through the introduction of deep electron traps. Understanding the electronic structure of the defects therefore is critical to optimizing material performance.

This work focuses on a theoretical determination of the impact of dislocations on the electronic properties of CdTe. First-principles calculations based on density functional theory are used to study the atomic and electronic structure of prototypical screw and edge dislocation cores in CdTe. The accuracy of the description of long-range strain around the dislocation core is studied by carefully examining finite-size and edge termination effects in the atomic models. From the atomic-scale structural descriptions of the dislocation cores, we obtain their associated spectra of gap electronic states using large-scale electronic structure calculations, allowing direct assessment of the impact on device electrical performance.

Prepared by LLNL under Contract DE-AC52-07NA27344; funded by the National Nuclear Security Administration Office of Nonproliferation and Verification Research and Development (NA-22).

8852-9, Session 3

Heavy metal ternary halides for room-temperature x-ray and gamma-ray detection

Zhifu Liu, John A. Peters, Maria Sebastian, Bruce W. Wessels, Northwestern Univ. (United States); Constantinos Stoumpos, Mercouri Kanatzidis, Northwestern Univ. (United States) and Argonne National Lab. (United States); Jino Im, Arthur J. Freeman, Northwestern Univ. (United States)

Efficient x-ray and gamma-ray radiation detectors have attracted interest for nondestructive testing, medical imaging, and security applications. For radiation detection at room temperature, semiconductor compounds with wide bandgaps, high average atomic numbers, high resistivity, and high mass densities are sought after. Compound semiconductors such as CdZnTe, CdTe, HgI2, PbI2, and TlBr are finding applications as detector development continues. We report our recent developments on synthesis, crystal growth, and characterization of the ternary heavy metal halides CsPbBr3 and CsPbCl3 for room temperature radiation detectors. The compounds are grown by a modified Bridgman method. The size of cut crystals is 2.1mm in thickness, 7.0mm in diameter. At room temperature, CsPbBr3 has an orthorhombic Pnma structure, and CsPbCl3 has the I4/mmm tetragonal structure. CsPbBr3 and CsPbCl3 have melting points at 567, and 610 degree Celsius, respectively. The absorption coefficients and bandgap energies were determined from UV-Vis-near IR transmission and reflection spectra. The energy bandgaps of CsPbBr3 and CsPbCl3 are 2.24 eV and 2.86 eV, respectively. The mobility-lifetime products for electron and hole carriers were determined from photoconductivity measurements. The measured mobility-lifetime products of CsPbBr3 for electron and hole carriers are 1.7x10^(-3), 1.3x10^(-3) cm^2/V, respectively. A key property that affects detector performance is the minority carrier lifetime. The lifetime of minority carrier (electron) is 2.54 microseconds as measured by photoconductivity decay. Photoluminescence spectroscopy was used to determine radiative defects present in these materials. Band edge emission in the 2.29 - 2.38 eV spectral region was observed at 30-80 K. We measured the x-ray spectral response of CsPbBr3 detector to Ag x-ray radiation at 295 K. It has a well-resolved spectral response to the 22.4 keV Ka radiation peak. Its efficiency is comparable to that of a commercial CdZnTe detector.

8852-10, Session 3

Basic studies on x-ray fluorescence analysis for active x-ray spectrometer on SELENE-2

Hiroki Kusano, Nobuyuki Hasebe, Hiroshi Nagaoka, Takuro Kodama, Yuki Oyama, Reiko Tanaka, Yoshiharu Amano, Waseda Univ. (Japan); Kyeong J. Kim, Korea Institute of Geoscience & Mineral Resources (Korea, Republic of); Jose A. Matias Lopes, Univ. de Coimbra (Portugal) and Instituto Superior de Engenharia de Coimbra (Portugal)

The active X-ray spectrometer (AXS) is now being developed as a payload candidate for SELENE-2, a next Japanese lunar exploration mission. The AXS is an in-situ X-ray fluorescence analyzer, which is to

determine the concentrations of major and sub-major elements and to characterize the geochemistry of lunar rocks and regolith around the landing site. The AXS will provide better understandings of the present lunar surface and its formation process. The AXS consists of a silicon drift detector (SDD) and multiple pyroelectric X-ray generators, and is to be installed on the top of rover arm together with a rock abrasion tool (RAT). The surface of lunar rock samples is needed to be grinded using the RAT because the surface of lunar rocks is weathered by the space weathering effect due to meteoroids and energetic particles. In this study, we have been investigating the X-ray fluorescence analysis (XRF) of rocks for evaluating the requirements for AXS on the Moon. The effect of surface roughness of rocks and the angle between incident and outgoing X-rays in XRF were studied from experiments and simulations. The XRF experiments were carried out using a SDD and an X-ray tube in a vacuum chamber. Geochemical reference samples with different surface roughness were used for the experiments. The XRF simulations were also carried out using the PENELOPE code. Fluorescent X-ray counts for some chemical elements were found to depend on the roughness and angle. The results of XRF for the AXS on SELENE-2 will be presented and discussed.

8852-11, Session 3

ZnO thin-film transistors for radiation environment applications

J. Israel Ramirez, Yuanyuan V. Li, Hitesh Basantami, The Pennsylvania State Univ. (United States); Gregg H. Jessen, Air Force Research Lab. (United States); Thomas N. Jackson, The Pennsylvania State Univ. (United States)

Radiation tolerance is of interest for space use and harsh environment applications such as nuclear reactors, and high-energy particle accelerators. While properly designed Si MOSFETS are usefully radiation resistant, most thin-film transistors (TFTs), including polysilicon and a-Si:H, are severely degraded by relatively low irradiation dose (typically <1 MRad). ZnO is a versatile semiconductor with a wide bandgap (Eg = 3.37 eV). The bonding in ZnO is strongly ionic and states near the conduction band minimum arise almost completely from cation (zinc) s-orbitals. This is in strong contrast to covalent or nearly covalent semiconductors like Si or GaAs where sp-bonding is sensitive to both bond angle and bond length disorder that easily generates localized states (traps). In ZnO, the nearly spherical and relatively large orbitals that form the conduction band result in electronic transport that is largely unaffected by bond angle or bond length disorder and disorder does not easily result in localized states.

We have done 60Co gamma ray irradiation testing of ZnO TFTs with and without electrical bias. The ZnO semiconductor and Al2O3 dielectric films used in these TFTs were deposited by weak oxidant plasma enhanced atomic layer deposition (PEALD). Devices irradiated without bias have only small changes in electrical properties for dose up to 100 Mrad; TFTs irradiated while biased in the linear or saturation region have somewhat larger changes. Irradiation induced changes for both biased and unbiased TFTs are nearly completely removed by a 60 s anneal at 200 °C.

8852-12, Session 3

Fabrication of high-resolution n-type 4H-SiC epitaxial layer alpha particle detectors and electronic noise analysis

Kelvin J. Zavalla, Sandeep K. Chaudhuri, Krishna C. Mandal, Univ. of South Carolina (United States)

In the present work high-resolution alpha particle detectors have been fabricated on high quality 20 micron thick n-type 4H-SiC epitaxial layers. A micropipe density lower than 1 cm^-2 was evaluated in the epilayers using Nomarski optical microscopy and scanning electron microscopy. Schottky barrier detectors have been fabricated by depositing 10 nm thick nickel contacts on the Si face of the epilayers. The detectors were characterized using current-voltage (I-V), capacitance-voltage (C-V) and alpha spectroscopic measurements. I-V measurements revealed a typical barrier height of ~1.6 eV, diode ideality factor of 1.09, and leakage current of the order of 14 pA at an operating bias of 110 V. C-V measurements revealed low effective doping concentrations of 2.4 x 10^14 cm^-3 in the epilayers. Pulse-height spectroscopy exhibited energy resolution as high as 0.37 % for 5.48 MeV alpha particles with a detector active area of 11 mm^2. A diffusion length of ~13.2 micron for holes has been determined in these detectors following a calculation based on a drift-diffusion model. Detailed electronic noise analysis in terms of equivalent noise charge (ENC) was carried out to study the effect of various noise components that contribute to the total electronic noise in the detection system. Shaping time and bias dependence of ENC has been studied in details. The noise analysis revealed that the white series noise due to the detector capacitance has substantial effect on the detector's overall performance.

8852-13, Session 3

Photoemission spectroscopic analysis of chemically modified TlBr surfaces for improved radiation detectors

Art J. Nelson, Lawrence Livermore National Lab. (United States); Jun-Sik Lee, SLAC National Accelerator Lab. (United States); Lars F. Voss, Patrick R. Beck, Robert T. Graff, Erik Swanberg, Adam M. Conway, Rebecca J. Nikolic, Stephen A. Payne, Lawrence Livermore National Lab. (United States); Hadong Kim, Leonard J. Cirignano, Kanai S. Shah, Radiation Monitoring Devices, Inc. (United States)

Device-grade TlBr was subjected to various chemical treatments used in room temperature radiation detector fabrication to determine the resulting surface composition and electronic structure. Samples of as polished TlBr were treated separately with 10%HCl, 96%SOCl2, 2%Br:MeOH and 10%HF solutions. High-resolution photoemission measurements on the valence band electronic structure and Tl 4f, Br 3d, Cl 2p and S 2p core lines were used to evaluate surface chemistry. Results suggest anion substitution at the surface with subsequent shallow heterojunction formation. Surface chemistry and valence band electronic structure were further correlated with the goal of optimizing the long-term stability and radiation response.

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. The Domestic Nuclear Detection Office in the Department of Homeland Security also supported this work. Portions of this research were carried out at the Stanford Synchrotron Radiation Lightsource, a Directorate of SLAC National Accelerator Laboratory and an Office of Science User Facility operated for the U.S. Department of Energy Office of Science by Stanford University.

8852-14, Session 4

pnCCDs for imaging and spectroscopy of x-rays up to 100 keV *(Invited Paper)*

Lothar Strueder, Sebastian Ihle, Robert Hartmann, Julia Schmidt, Martin Huth, Heike Soltau, Dieter Schlosser, Gerhard Lutz, PNSensor GmbH (Germany); Sebastian Send, Ullrich Pietsch, Ali Abboud, Univ. Siegen (Germany)

X-ray CCDs have been used in the past for imaging and spectroscopy of X-rays in the energy band from 100 eV up to 10 keV in X-ray astronomy, material and synchrotron science. An extension towards higher energies was realized in several applications by coupling the CCDs to scintillators. Only a few attempts were made to simultaneously exploit the good spectroscopic properties of the direct detection of X-rays in the silicon

bulk and the conversion of the X-rays into visible light in a scintillator coupled to the same CCD. We report on a concept of a pnCCD coupled to an inorganic scintillator (CsI (Tl)) for use in synchrotron experiments with hard X-rays up to 100 keV like PETRA3, BESSY 2 or ESRF. In case the X-rays are interacting in the 500 μm volume of the fully sensitive pnCCD bulk, the created electron-hole pairs deliver position and amplitude with high resolution. In case the interaction takes place in the scintillator the generated light spreads over many pixels. At that point the quantum detection efficiency is close to one, position can be precisely reconstructed but the energy resolution is poor. As the scintillation light levels in the pixel are low, the system must be operated with very low noise. Signals from X-rays directly converted in the silicon and the light from the scintillator may overlap, but can be separated offline. The relevant parameters of such a system were studied and the perspectives for the use in dedicated diffraction experiments at synchrotrons were derived.

8852-15, Session 4

Compact low-noise preamplifier for noise spectroscopy with biased photodiodes in cargo inspection systems

Bob Benetti, Advanced Design Services Corp. (United States); Willem G. J. Langeveld, Rapiscan Systems Labs. (United States)

Noise Spectroscopy, a.k.a. Z-determination by Statistical Count-rate ANalysis (Z-SCAN), is a statistical technique to determine a quantity called the “noise figure” from digitized waveforms of pulses of transmitted x-rays in cargo inspection systems. Depending only on quantities related to the x-ray energies, it measures a characteristic of the transmitted x-ray spectrum, which depends on the atomic number, Z, of the material penetrated. The noise figure can thus be used for material separation [1][2]. In an 80-detector prototype, scintillators are used with large-area photodiodes biased at 80V and digitized using 50-MSPS 12-bit ADC boards. We present an ultra-compact low-noise preamplifier design, with one high-gain and one low-gain channel per detector for improved dynamic range. To achieve adequate detection sensitivity and spatial resolution, each dual-gain preamplifier channel must fit within a 12.7 mm wide circuit board footprint and maintain adequate noise immunity to conducted and radiated interference from adjacent channels. The novel design included iterative SPICE analysis of transient response, dynamic range, frequency response, and noise analysis to optimize the selection and configuration of amplifiers and filter response. We discuss low-noise active and passive components and low-noise techniques for circuit board layout that are essential to achieving the design goals, and how the completed circuit board performed in comparison to the predicted responses.

Exploitation of geometric occlusion and covariance spectroscopy in a gamma sensor array

Sanjoy Mukhopadhyay, Richard J. Maurer, Stephen E. Mitchell, Paul P. Guss, Jack Meade, Kendall G. Braithwaite, Ronald E. Guise, National Security Technologies, LLC (United States)

The National Security Technologies, LLC, Remote Sensing Laboratory has recently used an array of six small-footprint (1-inch diameter by 3-inch long) cylindrical crystals of thallium-doped sodium iodide scintillators to obtain angular information from discrete gamma ray emitting point sources. Obtaining angular information in a near-field measurement for a field-deployed gamma sensor is a requirement for radiological emergency work. Three of the sensors sit at the vertices of a 2-inch isosceles triangle, while the other three sit on the circumference of a 3-inch-radius circle centered in this triangle. This configuration exploits occlusion of sensors, correlation from Compton scattering within a detector array, and covariance spectroscopy, a spectral coincidence technique.

Careful placement and orientation of individual detectors with reference to other detectors in an array can provide improved angular resolution for determining the source position by occlusion mechanism. By evaluating the values of, and the uncertainties in, the photopeak areas, efficiencies, branching ratio, peak area correction factors, and the correlations between these quantities, one can determine the precise activity of a particular radioisotope from a mixture of radioisotopes that have overlapping photopeaks that are ordinarily hard to deconvolve. The spectral coincidence technique, often known as covariance spectroscopy, examines the correlations and fluctuations in data that contain valuable information about radiation sources, transport media, and detection systems. Covariance spectroscopy enhances radionuclide identification techniques, provides directional information, and makes weaker gamma-ray emission—normally undetectable by common spectroscopic analysis—detectable. A series of experimental results using the concept of covariance spectroscopy are presented.

8852-19, Session 4

Characterization of the Yale PIXeY two-phase xenon detector

Nicholas E. Destefano, Moshe Gai, Univ. of Connecticut (United States); Daniel McKinsey, Yale Univ. (United States); Ethan Bernard, Univ. of Connecticut (United States); Sidney B. Cahn, Yale Univ. (United States); Blair Edwards, Alexey Lyshenko, Nicole Larsen, Christopher G. Wahl, Univ. of Connecticut (United States)

PIXeY (Particle Identification in Xenon at Yale) is a two-phase (liquid/gas) xenon prototype detector with 3-kg active mass. The two-phase xenon technology has many applications that include gamma-ray imaging, neutrinoless double beta decay searches, and dark matter searches. PIXeY was built to optimize energy resolution and gamma/neutron discrimination, with a number of technological improvements over previous work. Parallel-wire grids, which control the drift and proportional-scintillation fields, are optimized both for light collection efficiency and field uniformity. High quantum efficiency Hamamatsu R8778 PMTs, high-reflectivity Teflon walls, and charge-light anti-correlation techniques are also incorporated. PIXeY will serve as a platform for future improvements, including multiple optical volumes and single wire readout for R&D on gamma-ray imaging and track-imaging studies. The latest progress on the detector will be presented.

8852-20, Session 5

Experimental and computational results on exciton/free-carrier ratio, hot/thermalized carrier diffusion, and linear/nonlinear rate constants for scintillator proportionality *(Invited Paper)*

Richard T. Williams, Joel Q. Grim, Qi Li, Kamil B. Ucer, Wake Forest Univ. (United States); Gregory A. Bizarri, Lawrence Berkeley National Lab. (United States); Sebastien Kerisit, Fei Gao, Pacific Northwest National Lab. (United States); Pijush Bhattacharya, Eugene Tupitsyn, Emmanuel Rowe, Vladimir Buliga, Arnold Burger, Fisk Univ. (United States)

Various models of nonproportional response in scintillators have highlighted the importance of parameters such as branching ratios, carrier thermalization times, diffusion, kinetic order of quenching and associated rate constants, and radius of the electron track. For example, the fraction ηeh of excitations that are free carriers versus excitons was shown by Payne et al to have strong correlation with the shape of electron energy response curves from Compton-coincidence studies. Rate constants for nonlinear quenching are implicit in almost all models of nonproportionality, and some assumption about track radius must invariably be made. Diffusion, affecting time-dependent track radius and thus density of excitations, has been implicated as an important factor in nonlinear light yield, and several groups have recently highlighted diffusion of hot electrons in addition to thermalized carriers and excitons in scintillators. However, experimental determination of many of these parameters in the insulating crystals used as scintillators has seemed difficult. Subpicosecond laser techniques including interband z scan light yield, fluence-dependent decay time, and transient optical absorption are now yielding experimental values for several of the rates and ratios needed for modeling scintillator response. First principles calculations can fill in additional parameters still unavailable from experiment. As a result, quantitative modeling of scintillator electron energy response from independently determined material parameters is becoming possible in a small but growing number of materials. This paper describes our recent laser experiments, calculations, and numerical modeling of scintillator response. Supported by NNSA, Office of Nonproliferation Research and Development (NA-22) contracts DE-NA0001012 and DE-AC02-05CH11231.

8852-21, Session 5

Photosensor characterization for the Cherenkov Telescope Array: SiPM vs MAPMT

Aurelien Bouvier, David C. Williams, Andrey Kuznetsov, Caitlin Johnson, Lloyd Gebremedhin, Univ. of California, Santa Cruz (United States)

The Cherenkov Telescope Array (CTA) is an advanced facility for ground-based gamma-ray astronomy which is currently in its preparatory phase. Using an array of optical telescopes deployed over >1 km^2, CTA will detect flashes of Cherenkov light from electromagnetic showers originating from the interaction of GeV-TeV gamma rays with the Earth's atmosphere. The telescope cameras consist of hundreds to thousands of fast photosensors to discriminate gamma-ray showers from the unavoidable light of the night sky background.

It is envisioned that the array will be partly composed of telescopes using a Schwarzschild-Couder two mirror design which has never been built before. With its improved optics compared to the conventional Davies-Cotton design, the Schwarzschild-Couder design will allow larger field of view with smaller pixel and camera size opening the door to new types of photodetectors in the field of gamma-ray astronomy.

In this talk, we will present an extensive and detailed study of the two most promising devices being considered for this telescope design: silicon photomultipliers and multianode photomultiplier tubes. We evaluated the most critical performance characteristics for imaging gamma-ray showers: photo-detection efficiency, cross-talk, dark noise, pulse shape, afterpulsing, temperature dependence, and aging. We present our results in a cohesive manner to clearly evaluate the advantages and disadvantages that both types of device have to offer in the context of GeV-TeV gamma-ray astronomy.

8852-23, Session 5

A hybrid detecting system based on position sensitive scintillation detector and HPGe detector

Ivan Kojouharov, GSI Helmholtzzentrum für Schwerionenforschung GmbH (Germany); Tugba Arici, GSI Helmholtzzentrum für Schwerionenforschung GmbH (Germany) and Istanbul Univ. (Turkey); Jürgen Gerl, GSI Helmholtzzentrum für Schwerionenforschung GmbH (Germany); Nizamettin Erduran, Istanbul Sabahattin Zaim Univ. (Turkey)

In the last years great attention is paid on segmented HPGe detectors as a powerful tool for gamma-spectroscopy of exotic nuclei and gamma imaging. The measurement technology relies on pulse shape analysis followed by tracking of the photon interactions inside the detector [1], [2]. Such an approach requires very large number of electronics channels, each one connected to the corresponding segment, resulting in an enormous complexity of the apparatus.

For some gamma-spectroscopy applications as e.g. in-beam spectroscopy at high beam energies, where the Doppler correction of the photon energy deposited in the detector is crucial, or the gamma-camera, where the granularity of the front detector is of paramount importance, another less complex detection approach has been studied. It is based on a hybrid telescope-like system of a scintillation detector (Scatterer) and an HPGe detector (Absorber). The first photon interaction, most likely Compton scattering, occurs with high probability in the front placed position sensitive scintillation detector [3] and the scattered photon enters an HPGe crystal placed behind where its absorption is expected. The coincidence of these two events determines an useful event whose energy is the sum of the energy deposited in the both detectors. By using of a modern scintillation material as LaBr, CeBr or SrI, the good energy resolution of the HPGe detector will not be severely destroyed at the same time the position resolution of the Scatterer would enable Doppler correction. Additionally, fast timing may be achieved.

We studied experimentally by coincidence scanning technique [4] and by simulations the performance of such a hybrid detecting system. Special attention has been paid on the scintillation detector performance and its optimization, e.g. the detector thickness and the self-activity problem. The results of this study and the ongoing analysis and optimization of the system will be presented.

8852-24, Session 6

Effect of inclusions on thermal neutron detection with a semiconducting 6LiInSe2 crystal *(Invited Paper)*

Ashley C. Stowe, Y-12 National Security Complex (United States); Eugene Tupitsyn, Pijush Bhattacharya, L. Matei, Michael Groza, Brenden Wiggins, Arnold Burger, Fisk Univ. (United States)

Chalcopyrite semiconductors such as 6LiInSe2 potentially can be used as efficient alternatives to gas or scintillator thermal neutron detectors. Including a neutron absorber (6Li) into the regular stoichiometry of a bulk semiconductor increases the detection volume compared to layered detector. 6LiInSe2 crystals were synthesized from enriched 6Li metal which was chemically purified to 99.999% and grown by the Vertical Bridgman method. A single crystal of 12.8 mm diameter and 1.98 mm thickness has successfully detected a series of alpha, gamma, and thermal neutron signatures. 6LiInSe2 crystals have high resistivity (>10^12 Ω*cm); however, many inclusions are present. Laser induced breakdown spectroscopy and IR microscopic studies have been undertaken to determine the composition and orientation of these inclusions. Subsequent optimization of crystal growth has been undertaken to improve upon inclusion concentrations and thereby improve charge collection in a detector. Radiation measurements were conducted on these improved crystals.

8852-25, Session 6

Solid-state thermal neutron detectors based on hexagonal boron nitride epilayers

Hongxing Jiang, Sam Grenadier, Tri D. Doan, Sashikanth Majety, Jing Li, Jingyu Lin, Texas Tech Univ. (United States)

Boron-10 isotope has a capture cross-section of 3840 barn for thermal neutrons (with 0.025 eV energy), which is orders of magnitude larger than many isotopes. Hexagonal boron nitride (hBN) semiconductor epitaxial films have been synthesized by metal organic chemical vapor deposition. Thermal neutron absorption lengths have been measured to be about 238 µm and 67 µm for natural and 10B enriched hBN epilayers, respectively.

Neutron detectors were fabricated from hBN epilayers. Systematic studies were carried out on the correlation between the material growth conditions, carrier mobility-lifetime product, dark current and the neutron detector performance. Excellent performance of hBN neutron detectors has been demonstrated through high thermal neutron conversion efficiency, low leakage current, and low operating voltages. At room temperature, the leakage current (or dark current) density of hBN detectors is about 10^-11 A/cm^2 at a bias voltage of 10 V [1].1 A continuous irradiation with a thermal neutron beam generated an appreciable steady current response in hBN detectors, corresponding to an effective conversion efficiency approaching ~80% for absorbed neutrons [2]. Radiation damage to the hBN neutron detectors is being assessed by subjecting the devices to a prolonged irradiation by the 252Cf source and the results will be reported. Our results indicate hBN neutron detectors have the potential to replace He-3 gas detectors, which faces the very serious issue of He-3 gas shortage.

8852-27, Session 7

Spectral resolution in pixel detectors with single-photon processing *(Invited Paper)*

Christer Frojdh, Mid Sweden Univ. (Sweden)

Pixel detectors based on photon counting or single photon processing are becoming popular for spectral X-ray imaging. The detector is based on deep submicron electronics with functions to determine the energy of each individual photon in every pixel. The system is virtually noiseless when it comes to the number of the detected photons. However noise and variations in system parameters affect the determination of the photon energy.

Several factors affect the energy resolution in the system. In the readout electronics the most important factors are the threshold dispersion, the gain variation and the electronic noise. In the detector contributions come from charge sharing, variations in the charge collection efficiency and the statistical nature of the charge generation, as described by the Fano factor.

The MEDIPIX technology offers a powerful tool for investigating these effects since energy spectra can be captured in each pixel. In addition the TIMEPIX chip, operating in Time over Threshold mode, offers an opportunity to analyze individual photon interactions, thus addressing charge sharing and fluorescence. Effects of charge sharing and the properties of charge summing are investigated using MEDIPIX3RX. Experiments are performed using both Si and CdTe detectors operating in hole collection and electron collection mode.

In this paper we discuss the various contributions to the spectral noise and how they affect detector response. The statements are supported with experimental data from MEDIPIX-type detectors.

8852-28, Session 7

Zn effects on the reconstructions of the Cd-terminated CdTe (111) surface

Jin Li, Nicholas Kioussis, California State Univ., Northridge (United States); Suleyman Tari, Christoph H. Grein, Fikri Aqariden, Sivananthan Labs., Inc. (United States)

Cadmium telluride (CdTe) and cadmium zinc telluride (CZT) are known to have great potential in room-temperature X-ray and gamma ray semiconductor detector applications. Besides the quality of bulk crystal, the quality of the CdTe (CZT) surfaces and interfaces are often the dominant factors influencing the detector performance. Various surface reconstructions have been observed by experiments which remain controversial. Our previous theoretical study demonstrated that the most stable structure of Cd-terminated CdTe (111) A surface is the (2?2) reconstruction at high temperatures corresponding to the surface cadmium-vacancy model and the (√3x√3)R30° reconstruction is not stable for the pure CdTe (111) A surface [1]. However, we found that the Zn alloy can change the relative stability of surface reconstructions of CdZnTe (111) A surface. In this work, we studied the the phase transitions between (2?2) to (√3x√3)R30° reconstruction by employing ab initio thermodynamics calculations. The mechanism of the transition is the large local deformation and the surface relaxation induced by Zn. Our theoretical study has explained the experimentally observed (√3x√3)R30° reconstruction for the Cd0.96Zn0.04Te alloyed surface.

8852-29, Session 7

Development of a high-performance detection system for the hard x-ray astronomy (1-200 keV) based on a germanium double-sided strip detector

Isidre Mateu, Jean-Pierre Roques, Odile Coeur-Joly, David Murat, Elsa Andre, Jacques Lande, Elisabeth Jourdain, Institut de Recherche en Astrophysique et Planétologie (France); Patrice Medina, Observatoire Midi-Pyrénées (France); Cedric Mathieu, Ctr. National de la Recherche Scientifique (France)

The development of a high purity germanium (HPGe) double sided strip detector prototype for X-ray astronomy is presented. The proposed design will cover energies between 1 and 200 keV, and consists of a 4x4x1cm bulk with contacts on each side orthogonally segmented into 100 strips of a width of 350µm, with 50µm of gap between strips. Both spectrometry and imaging capabilities have been taken into account in the design of the detector: on one hand, the use of germanium guarantees high spectral resolution; on the other hand, finely segmented contacts provide high sensitivity on the position determination in the plane of the detector. In addition, the depth of the interaction can be estimated by looking at the difference of pulse raise time between the anode and the cathode. Pulse shape analysis and advanced algorithms are used for this purpose, obtaining a three-dimension localization of the point of impact of the photons. Furthermore, multiple interaction occurring simultaneously can be located, which makes the detector a suitable instrument for polarization measurements. The detection system relies on the extensive use of digital signal processing, with an early sampling of the signal at the output of the charge amplifier. This paper presents the measurement chain, including the detector itself, the electronic readout system and the signal processing methods that have been used. The main results of the laboratory tests carried out at this stage are presented, and finally the observed performances of the detector are discussed.

8852-30, Session 7

New modification of xenon gamma-ray detector with high-energy resolution

Alexander S. Novikov, Sergey E. Ulin, Valery V. Dmitrenko, Zietdin M. Uteshev, Konstantin F. Vlasik, Victor M. Grachev, Irina V. Chernysheva, Alexander E. Shustov, National Research Nuclear Univ. MEPhI (Russian Federation)

The results of the development of the new modified xenon gamma-ray detector (XGD) are presented. This detector differs from the previously created ones in improved energy resolution ((1.7±0.1) % at 662 keV) and ability to work in hard acoustic conditions (up to 100 dB) practically without changes of spectrometric characteristics. These results have been achieved by developing a digital method of processing of each electric signal from XGD. On the basis of this method the digital electronics based on FPGA have been created.

The new gamma-ray detector can be widely used for different fundamental and applied tasks such as ecological radiation monitoring, nuclear reactor control, countering nuclear terrorism, radiation customs control, etc. In particular it is planned to use this device onboard unmanned aircraft vehicles for ecological monitoring of areas close to nuclear industry objects. Furthermore, XGD is included into the scientific equipment of the spacecraft "Interheliozond", which will approach the Sun to a distance of its 60-70 radiuses along a spiral trajectory.

8852-31, Session 7

Metal contacts on chemo-mechanically polished CdZnTe for radiation detector applications

Suleyman Tari, Fikri Aqariden, Yong Chang, Sivananthan Labs., Inc. (United States); Christoph H. Grein, Univ. of Illinois at Chicago (United States); Jin Li, Nicholas Kioussis, California State Univ., Northridge (United States)

Advanced radiation detectors with high gamma-ray energy resolution, linear energy response and the capability of room temperature operation in both normal counting and spectroscopic modes are highly desirable for many applications such as medical diagnostics, non-destructive industrial evaluation, homeland security and counter-terrorism inspections, as well as non- or counter-proliferation detection to ensure national and international nuclear safety. State-of-the-art room temperature, high resolution x-ray and gamma-ray detectors are usually based on CdZnTe semiconductors. The structural and electronic properties of CdZnTe surfaces, especially surface/contact metal interfaces, have a significant impact on radiation detector performance, such as leakage current, signal to noise ratio and energy resolution, especially for relatively soft x-ray photons and large pixilated arrays. Atomically smooth and defect-free surfaces are desirable for high performance CdZnTe-based detectors; chemo-mechanical polishing is typically preformed to produce such smooth CdZnTe surfaces. We present a detailed study on the structural and electronic properties, and hence detector performance, of various metal contacts on chemo-mechanically polished CdZnTe surfaces of about 1 nm roughness. The surface morphology and surface electronic properties were studied with atomic force microscopy and x-ray photoelectron spectroscopy (XPS), and devices with current voltage (I-V) measurements and energy resolution analyses. XPS results indicate that the as-polished and metal-contacted surfaces are not stoichiometric. I-V measurements show either ohmic or rectifying behaviour depending on the contact metal and deposition procedures.

8852-32, Session 8

Optical design and signal processing for high-resolution gamma spectroscopy with large-volume scintillator detectors *(Invited Paper)*

Nerine J. Cherepy, Stephen A. Payne, Erik Swanberg, Patrick R. Beck, Robert D. Sanner, Thomas M. Tillotson, Lawrence Livermore National Lab. (United States); Kanai S. Shah, Rastgo H. Hawrami, Radiation Monitoring Devices, Inc. (United States); Arnold Burger, Fisk Univ. (United States); Lynn A. Boatner, Oak Ridge National Lab. (United States); Michael Momayezi, Bridgeport Instruments, LLC (United States)

This presentation will describe the challenges of large volume scintillator detector design for high energy resolution gamma spectroscopy. Surface finish, optical geometry and diffuse reflector optimization can be implemented for improved readout with analog electronics. In addition, for scintillator materials that exhibit light-trapping (scintillation emission is re-absorbed and re-emitted prior to detection), digital scintillation trace acquisition and processing can be employed to improve the energy resolution for large volume scintillators. Europium-doped Strontium Iodide and Bismuth-loaded plastics in 3-15 in3 sizes will be presented as example scintillators amenable to this approach.

8852-33, Session 8

Analysis of scintillator crystal production via the edge-defined film-fed growth method

Andrew Yeckel, Univ. of Minnesota (United States); Robert S. Feigelson, Stanford Univ. (United States); Jeffrey J. Derby, Univ. of Minnesota (United States)

A model of edge-defined film fed (EFG) crystal growth is developed to study melt growth of cylinders of the scintillator crystal cesium iodide (CsI). This system is characterized by strongly nonlinear interactions of heat transfer, capillarity, and die geometry that give rise to multiple solution states under a single set of operating conditions. Purely capillary instabilities are identified that result from the interaction of surface tension with gravity. These give rise to two solution families distinguished by a difference in gap width between die face and growth interface. The narrow gap solutions are shape stable, and the wide gap solutions are shape unstable, though these can be stabilized by heat transfer similar to Czochralski growth. Additionally we identify several instabilities of convective heat transfer, which generally are of two types. One type is mostly convective in nature and largely independent of the interface or meniscus shapes. The other type is characterized by a strong interaction of convection with the geometry of the growth interface. Stronger convection moves the interface to a higher position, forming a larger gap. The larger gap allows a stronger flow to form, which enhances convection. This reinforcing behavior enables a family of solutions to exist in which the growth interface shape is concave in the central region, though it is convex elsewhere.

8852-34, Session 8

GYGAG(Ce) detector array with silicon photodiode readout

Erik Swanberg, Nerine J. Cherepy, Stephen A. Payne, Zachary M. Seeley, Patrick R. Beck, Lawrence Livermore National Lab. (United States); Joel M. Kindem, Digirad Corp. (United States)

Cerium doped GYGAG, (Gd,Y)(Ga,Al) Garnet, scintillators offer high light yields of ~50,000 Ph/MeV for high energy resolution, relatively high density of 5.8 g/cm3 for good stopping power and high Zeff of 48 for good photoelectric absorption. However, GYGAG(Ce) emission is centered in the green at ~550 nm, resulting in poor quantum efficiency of ~10% with typical photomultiplier tubes (PMTs). Fortunately, the longer wavelength emission couples well to Si photodiodes, offering quantum efficiency of ~80% in the green-red range. Further, photodiodes are smaller, lighter and more rugged than typical PMTs.

In order to minimize dark current, small area (3mm x 3mm) photodiodes are used. Using an array of small (3mm x3 mmx 6mm) GYGAG scintillators maintains the good resolution of GYGAG while allowing larger volumes of material to be used. We report here on our progress in engineering high resolution (<4% at 662 keV), low-power, lightweight GYGAG-Si photodiode arrays for hand held radioisotope identification devices (RIID's).

8852-35, Session 8

Temperature behavior of CLYC/MPPC detectors

Jarek Glodo, Andrey K. Gueorguiev, Rastgo H. Hawrami, Joshua P. Tower, Kanai S. Shah, Radiation Monitoring Devices, Inc. (United States)

Current radiation detection systems rely on He-3 tubes for thermal neutron detection. He-3 tubes are popular due to their good performance, simplicity and good intrinsic gamma-ray discrimination. Due to low stockpiles of He-3 gas and increased prices many manufacturers are looking to replace these detectors in their instrumentation. Since fissioning materials emitting neutrons are rare, detection of any neutrons above the natural background is a strong indication of special nuclear materials presence.

In order to meet the need of a replacement for He-3 detectors, during the last year we have been developing a detector based on the combination of Cs2LiYCl6 (CLYC) scintillator and a Multi-Pixel Photon Counter photo-detector (MPPC). CLYC offers efficient thermal neutron detection, excellent discrimination between gamma rays, and gamma-ray energy resolution. The detection efficiency of 1 cm3 of Li-6 enriched CLYC is more than twice as high as the same volume of He-3 at 8 atmospheres. Discrimination between gammas and neutrons is achieved through pulse height and pulse shape analysis. CLYC/MPPC detectors can also be used to detect gamma rays. These properties and a small size of overall detector not only make it a very promising He-3 tube replacement, but provide added capability not found in He-3 detectors.

In this presentation, we report on temperature dependencies of a CLYC/MPPC detector in the range of -20C to 50C (ANSI N42.34-2006) expected from hand-held instrumentation. This includes the changes in pulse height spectra, energy resolution for the gamma and neutron peaks, and pulse shape discrimination.

8852-36, Session 8

GaN as an ultrafast robust scintillator

Ke-Xun Sun, Univ. of Nevada, Las Vegas (United States)

We propose to use GaN as an ultrafast and robust scintillator for radiation detection. We have measured GaN photoluminescence spectral profile, which is centered at 365-369 nm [1]. Other groups have measured the GaN scintillation efficiency be 1E6 photons per MeV. We have also demonstrated the extreme proton radiation hardness of AlGaN/GaN optoelectronics devices [2, 3]. The AlGaN UV LED and UV photodiodes maintained their optical output or response up to 3E12 protons per square centimeter, which is equivalent to even better neutron radiation hardness. Further, GaN carrier relaxation time can be subpicoseconds, in both GaN material and quantum well structure. Currently we are working towards more detailed characterization of GaN optical photoluminescence using tunable ultrafast lasers, and GaN particle scintillation properties using neutron sources. This presentation will give an overview of our efforts.

8852-37, Session 9

Understanding fundamental mechanisms of nonproportionality in inorganic scintillators

(Invited Paper)

Fei Gao, Sebastien Kerisit, Yulong Xie, Micah Prange, Luke W. Campbell, Renee Van Ginhoven, Pacific Northwest National Lab. (United States)

We will review recent progress on computational approaches to understand the fundamental mechanisms that give rise to nonproportionality in inorganic scintillator materials. First, we will discuss Monte Carlo simulations of gamma-ray interaction with SrI2 and LaBr3, two promising scintillator materials, and resulting predictions of important intrinsic properties that include W (the mean energy required to create an e-h pair), the Fano factor, and maximum theoretical light yield as a function of incident energy. It is of interest to note that the photon energy at which W becomes constant is about 150 eV in SrI2, while it is about 2 keV in LaBr3 and 10 keV in CsI. This suggests that the light yield of SrI2 is nonlinear only at very low incident energies, which is consistent with experimental observations and in contrast to CsI in which the initial rise in the relative light yield with increasing incident energy extends up to a few keV. Furthermore, the distribution of electron-hole pairs in SrI2 shows a linear track behavior, while it is clustered along the tracks in LaBr3, which give rise to regions of high excitation density along the ionization track in LaBr3. Also, it is observed that most electron-hole pairs are produced by interband transitions in SrI2, but a significant number of electron-hole pairs are created by plasmon excitations (in addition to interband transition) in LaBr3. This increase in the number of effective energy loss channels may lead to nonproportionality at higher energies in LaBr3, as compared to that in SrI2.

Second, we will discuss recent kinetic Monte Carlo (KMC) simulations of nonlinear quenching in CsI, CsI(Tl) and NaI(Tl). In these simulations, the interactions between STEs are described via dipole-dipole Förster transfer and are parameterized using experimental data on the excitation density dependent light yield following ultraviolet excitation. The KMC simulations reveal that nonlinear quenching occurs very rapidly (within a few picoseconds) in the early stages of the scintillation process. In addition, the KMC simulations enable us to compare and contrast the extent and mechanism of nonlinear quenching in CsI(Tl) and NaI(Tl), whereby mixed second/third quenching is observed for the former whereas pure second order quenching is found for the latter at 5.9-eV excitation. Finally, the ability of the KMC model to reproduce available experimental data allows for elucidating the elementary processes that give rise to the kinetics and efficiency of scintillation observed experimentally for a range of conditions.

8852-38, Session 9

Growth and characterization of CdTeSe for room-temperature radiation detector applications

Utpal N. Roy, Aleksey E. Bolotnikov, Giuseppe S. Camarda, Ge Yang, Anwar Hossain, Yonggang Cui, Ralph B. James, Brookhaven National Lab. (United States); Alex Fauler, Michael Fiederle, Albert-Ludwigs-Univ. Freiburg (Germany); Malgorzata Sowinska, Gilbert Hennard, Paul Siffert, Eurorad S.A. (France)

The ternary compound CdTexSe1-x can be a good choice for room-temperature radiation detector applications. The compound has several advantages over CdZnTe, particularly the near unity segregation coefficient of Se in CdTe, which ensures axial and radial compositional uniformity of the grown ingots. The ability to obtain larger and more uniform detector-grade crystals has the potential to drastically reduce the production cost of detectors compared to CdZnTe. In the present paper we will discuss the growth and characterization of CdTexSe1-x crystals and offer some preliminary results on device properties.

8852-39, Session 9

Bulk growth of uniform and near stoichiometric cadmium telluride

Santosh K. Swain, Sachin Bhaladhare, Amlan Datta, Kelvin G. Lynn, Washington State Univ. (United States)

Non-stoichiometry related extended defects in CdTe/CZT, such as tellurium inclusions and precipitates are known to be detrimental bulk defects in both detector grade and mercury cadmium telluride substrate grade materials. Conventional approaches to maintain or restore crystal stoichiometry rely on the use of a separate Cd reservoir integrated to the ampoule and maintaining an appropriate temperature field near the source or post growth thermal treatment in Cd/CdZn environment. We prove that it is possible to grow inclusion (secondary phases > 1 micron) free bulk CdTe in a cost-time effective way without post growth processing or requiring any ampoule and furnace modifications. As part of a systematic approach to eliminate these defects, undoped bulk CdTe crystal growth was accomplished in a vertical Bridgman configuration. As grown wafers were characterized with respect to infrared transmission, foreign impurity concentration determined by glow discharge mass spectrometry (GDMS), and bulk electrical resistivity. Excepting for grain boundaries and twins, the wafers were found to be completely free of inclusions of sizes >1 micron and the distribution at different parts of the grown boule were found to be identical. Star shaped cadmium inclusions were observed at some places near middle section of the ingot. The samples tested from this ingot exhibited high bulk resistivity values of 108 to 109 ohm.cm, which was in conformity with the low density of nonstoichiometric defects. GDMS results indicated that the concentration of unintentional impurities were low enough for the electrical behavior to be explained uniquely on the basis of native defects.

8852-40, Session 9

Post-growth annealing of CdZnTe crystals: an analysis of defect-structures and opto-electronic properties

Ge Yang, Aleksey E. Bolotnikov, Brookhaven National Lab. (United States); Petro M. Fochuk, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Yonggang Cui, Giuseppe S. Camarda, Anwar Hossain, Utpal N. Roy, Ralph B. James, Brookhaven National Lab. (United States)

In this work, we investigate post-growth annealing to improve the properties of CdZnTe (CZT) crystals. Defect structures and opto-electronic properties of as-grown and annealed CZT crystals are characterized by IR transmission microscopy, white X-ray beam diffraction topography, current-voltage measurements, and low-temperature photoluminescence spectroscopy. New results from recent low-temperature and long-term annealing experiments will be presented and discussed.

8852-41, Session 10

Trap level analysis in CdZnTe and CdMnTe by I-DLTS, PICTS, TEES, and PL

Ki-Hyun Kim, Pilsu Kim, Korea Univ. (Korea, Republic of); Rubi Gul, Aleksey E. Bolotnikov, Giuseppe S. Camarda, Anwar Hossain, Brookhaven National Lab. (United States); Anna Cavallini, Univ. degli Studi di Bologna (Italy); Jan Franc, Charles Univ. in Prague (Czech Republic); Ralph B. James, Brookhaven National Lab. (United States)

Charge trapping and recombination are typical effects in semiconductors and generally prevent the complete charge collection in an X- and gamma-ray detector. Several experimental techniques such as photo-induced thermally stimulated current (TSC), current transient spectroscopy (PICTS), thermo-electric emission spectroscopy (TEES), photoluminescence (PL) and current deep-level transient spectroscopy (I-DLTS) had been applied for the trap analysis of CdTe and CdZnTe (CZT) material. However, the assigned trap energy levels were not same all the time due to the different sample properties and/or the different measurement technique. In this paper, we will present trap levels analysis of CZT:In and CdMnTe:In (CMT:In) measured by four different technique with same samples.

8852-42, Session 10

X-ray Response of CZT detectors for high-flux applications

Giuseppe S. Camarda, Aleksey E. Bolotnikov, Yonggang Cui, Brookhaven National Lab. (United States); Václav Dedic, Brookhaven National Lab. (United States) and Charles Univ. in Prague (Czech Republic); Anwar Hossain, Brookhaven National Lab. (United States); Ki-Hyun Kim, Kisung Lee, Korea Univ. (Korea, Republic of); Utpal N. Roy, Ge Yang, Ralph B. James, Brookhaven National Lab. (United States)

Several CZT detectors were evaluated by using the Micron-scale X-ray Detector Mapping (MXDM) system of beamline X27B at National Synchrotron Light Source (NSLS) of Brookhaven National Laboratory (BNL). The uniformity of the X-ray response maps for fabricated detectors is indicative of the performance of the detectors for high flux applications. The results will elucidate the defects responsible for the observed non-uniformities.

8852-43, Session 10

Contact scaling to high-resistivity compensated Cd1-xZnxTe

Arie Ruzin, Tel Aviv Univ. (Israel)

High resistivity semiconductors are essential for radiation detectors. The high resistivity in detector tailored semiconductors must be achieved by low concentration of free carriers rather than by low mobility. The semi-insulating resistivity implies semi-intrinsic charge carrier concentrations and it is seldom achieved by high material purity and crystalline perfection. In most cases a compensation mechanism is responsible for

the low material conductivity. Such is believed to be the case of wide bandgap II-VI compound semiconductors (CdTe, Cd1-xZnxTe, etc.). Depositing electrical contacts with reproducible macroscopic behavior remains challenging. Furthermore, detailed understanding of electrical contacts to such materials remains elusive.

In this study finite element calculations are used to investigate the contact scaling effects and surface states impact for various compensation mechanisms. The computation results shed light on the conditions inside the metal-semiconductor-metal (MSM) structures with various contacts. It is shown that the current-voltage dependence in the presence of the velocity saturation phenomena even for ideal Ohmic contacts become very dependent on the compensating level properties. In the case of Schottky contacts the deep levels properties strongly affect the current-voltage characteristics and the internal electric field distribution

8852-44, Session 10

Breakthrough development of large-volume high-performance cadmium zinc telluride radiation detector *(Invited Paper)*

Henry Chen, Jason M. MacKenzie, Joseph Kumar, Eric Chen, Adam Grosser, Jim Balcom, Glenn K. Bindley, Redlen Technologies (Canada); Feng Zhang, Zhong He, Univ. of Michigan (United States)

Latest development of Cadmium Zinc Telluride (CZT) radiation sensor grown by the traveling heater method (THM) is reported. Excellent detector performance, close to 1% energy resolution at 662 keV gammas at room temperature has been achieved on pixellated 20x20x15 mm3 CZT detector without spectral correction. Detector energy resolution reached 0.6% FWHM after depth of interaction (DOI) correction. This breakthrough of the technology has been achieved via our recent development in THM crystal growth in combination with our proven device fabrication technique. The achievement commends CZT as the material of choice for mass production of room temperature radiation detectors for applications in homeland security, medical imaging and space applications such as that used in Compton imaging (1).

Developing a high-resolution x-ray imager using electron multiplying (EM) CCDs

James H. Tutt, David J. Hall, Neil J. Murray, The Open Univ. (United Kingdom); James Endicott, e2v technologies plc (United Kingdom); Andrew D. Holland, The Open Univ. (United Kingdom)

Applications at synchrotron facilities such as macromolecular crystallography and high energy X-ray diffraction require high resolution imaging detectors with high dynamic range and large surface area. Current systems can be split into two main categories: hybrid pixel detectors and scintillator-coupled Charge-Coupled Devices (CCDs). Whilst both have limitations, CCD-based systems (coupled to fibre-optics to increase imaging area) are often used in these applications due to their small pixels and the high resolution. Electron-Multiplication CCDs (EM-CCDs) are able to suppress the readout noise associated with increased readout speed offering a low noise, high speed detector solution. A previous pilot study using a small-area (8mm x 8mm) scintillator-coupled EM-CCD found that through high frame-rates, low noise and novel uses of photon-counting, resolution could be improved from over 80 um to 25 um at 2 fps. To further improve this detector system, the high speed readout electronic developed for “lucky imaging” by the Institute of Astronomy, Cambridge, UK, can be used alongside a fibre-optic taper and EM-CCD to create a “best of both worlds” solution consisting of the high resolution of a CCD, along with the low noise, high speed (high dynamic range) and large effective area of pixel detectors. This paper details the developments in the study and discusses the latest results and their implication on the system design.

Direction-sensitive hand-held gamma-ray spectrometer

Sanjoy Mukhopadhyay, Stephen E. Mitchell, Jack Meade, Paul P. Guss, National Security Technologies, LLC (United States)

A novel, light-weight, hand-held gamma-ray detector with directional sensitivity is being designed. The detector uses a set of multiple rings around two cylindrical surfaces, which provides precise location of two interaction points on two concentric cylindrical planes, wherefrom the source location can be traced back by back projection and/or Compton imaging technique. The detectors are 1.5 x 1.5 mm europium-doped strontium iodide (SrI2: Eu2+) crystals, whose light output has been measured to exceed 120,000 photons/MeV, making it one of the brightest scintillators in existence. The crystal’s energy resolution, less than 3% at 662 keV, is adequate enough to bridge the resolution gap between sodium iodide and cadmium zinc telluride. The emission of SrI2: Eu2+ is well-matched to both photomultiplier tubes and blue-enhanced silicon photodiodes. The solid-state photomultipliers used in this design (each 1.5 x 1.5 mm) are arrays of active pixel sensors (avalanche photodiodes driven beyond their breakdown voltage in reverse bias); each pixel acts as a binary photon detector, and their summed output is an analog representation of the total photon energy, while the individual pixel accurately defines the point of interaction. This article will discuss Monte Carlo simulations made to determine if segmented crystal and/or position-sensitive photomultiplier tubes will increase directional sensitivity. A simple back-projection algorithm involving cone-surface mapping was modeled. The back projection for an event cone is a conical surface defining the possible location of the source. The cone axis is the straight line passing through the first and second interaction points.

This work was done by National Security Technologies, LLC, under Contract No. DE-AC52-06NA25946 with the U.S. Department of Energy.

8852-46, Session PWed

Design and construction of large-volume scintillation detector for pulsed neutron detection

Noushin Hajihassani, Atomic Organization of Iran (Iran, Islamic Republic of); Fereydoon Abbasi Davani, Shahid Beheshti Univ. (Iran, Islamic Republic of); Mohammad Javad Safari, Amirkabir Univ. of Technology (Iran, Islamic Republic of); Navid Delkash Rudsary, Shahid Beheshti Univ. (Iran, Islamic Republic of)

In this work, an NE-102 plastic scintillator has been chosen for neutron detection. The neutron energy deposition in any point of the detector has been calculated by MCNPX code, and then by using the light response curve of the scintillator the number of photons generated due to neutron energy deposition has been determined. Finally, light photon transport has been carried out by the OPTICS code, and the effect of detector surface paint on light collection has been investigated. Considering the paint effect, a 15x12x50 cm3 plastic scintillator cell was manufactured. After making the detector and calculating detector efficiency and comparing it with the results of simulations, the uniformity process can be observed between them. Then the large volume plastic scintillator detector is used for observing plasma focus neutron pulse as well as hard X-ray pulse. Because of the speed difference between produced neutrons and X-ray photons, if the detector is located in a proper

distance from the Plasma Focus, the neutron and X-ray pulses could be seen separately. Measurement results showed that 3.5 meters distance between the detector and the plasma focus is appropriate for observing neutron and X-ray pulses separately. A pulsed neutron and X-ray source in this experiment is a 2.5kJ Mather type plasma focus device (SBUPF1) in Shahid Beheshti University with average neutron flux~3x107[3].

GHz hard x-ray imaging using fast scintillators

Zhehui Wang, Elena Guardincerri, Los Alamos National Lab. (United States); Dennis D. Rathman, MIT Lincoln Lab. (United States); M. E. Azzouz, Cris W. Barnes, Los Alamos National Lab. (United States); Robert Berger, MIT Lincoln Lab. (United States); E. M. Bond, Los Alamos National Lab. (United States); David M. Craig, MIT Lincoln Lab. (United States); David B. Holtkamp, Jon S. Kapustinsky, Alexei V. Klimenko, Kris Kwiatkowski, R. B. Merl, Christopher L. Morris, J. O. Perry, Los Alamos National Lab. (United States); E. Ramberg, Fermi National Accelerator Lab. (United States); Robert K. Reich, MIT Lincoln Lab. (United States); A. Ronzhin, Fermi National Accelerator Lab. (United States); K. Warner, MIT Lincoln Lab. (United States); Richard T. Williams, Wake Forest Univ. (United States); Ren-Yuan Zhu, California Institute of Technology (United States)

GHz imaging technology will be needed at high-luminosity X-ray and charged particle sources. It is plausible to combine fast scintillators with the latest picosecond detectors and GHZ electronics for multi-frame hard X-ray imaging and achieve an inter-frame time of less than 10 ns. The time responses and light yield of LYSO, LaBr3, BaF2 and ZnO are measured using a MCP-PMT detector. ZnO is an attractive material for fast hard X-ray imaging based on GEANT4 simulations and previous studies, but the measured light yield from the samples is much lower than expected.

8852-48, Session PWed

Calculations of the energy dependence of the sensitivity for planar CdZnTe gamma-ray detectors

Alexandr A. Zakharchenko, Anna I. Skrypnyk, Manap A. Khazhmuradov, Alexandr V. Rybka, Vladimir E. Kutny, National Science Ctr. Kharkov Institute of Physics and Technology (Ukraine); Petro M. Fochuk, Valery M. Sklyarchuk, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Aleksey E. Bolotnikov, Ralph B. James, Brookhaven National Lab. (United States)

Considerable variations in the charge-carrier transport properties lead to the necessity of individual calibrations for CdZnTe gamma-ray detectors. Experimental measurement of the detectors' sensitivity in the gamma-quantum energy range of 0.04-3 MeV requires at least 10 different gamma-ray sources as references. For determining the energy dependence of the sensitivity for CdZnTe-detectors via a Monte-Carlo method, it is necessary to first measure the electron and hole mobility-lifetime products in each detector. Both methods for the determination of sensitivity of CdZnTe gamma-ray detectors require a lot of time, especially for the calibration of the response for multi-detector arrays. We carried out a set of experiments, wherein it was determined that the energy dependence of the sensitivity for planar CdZnTe detectors in the gamma-quantum energy range of 0.04-3.0 MeV can be reconstructed based on the results of measurements of pulse-height distributions with Am-241, Cs-137 and Co-60 sources. The errors for the obtained approximation formulae are compared with detailed calculations of CdZnTe-detectors' sensitivity via a Monte-Carlo method. The maximum error of the approximation formulae in the gamma-quantum energy range between 0.3 and 0.4 MeV was determined. We considered conditions in which the error of the approximation formulae compared with detailed Monte-Carlo calculations does not exceed 10%. The calculated values of the sensitivity are verified with the results of measurements with Eu-152 and Ba-133 sources. The calculated dependencies of the sensitivity of CdZnTe-detectors on the energy of the gamma-quanta can be used for estimating the changes in the charge-carrier transport parameters due to the accumulation of radiation-induced defects.

8852-49, Session PWed

Reasons of low-charge collection efficiency in CdTe detectors with ohmic contacts

Leonid A. Kosyachenko, Olena L. Maslyanchuk, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Toru Aoki, Shizuoka Univ. (Japan); Volodymyr A. Gnatyuk, V. Lashkaryov Institute of Semiconductor Physics (Ukraine)

The problems are analyzed caused by the limitation on operating voltage of CdTe-based X/gamma-ray detectors with ohmic contacts by a value not higher than 80-100 V for the crystal thickness of 1 mm. Electrical measurements at different temperatures show that a rapid increase in the leakage current with rising bias voltage is equivalent to the contribution of an additional temperature-independent current component. Such character of the temperature effect is evidence that an increase in the current at higher voltages is caused by tunneling of minority carriers through the potential barrier created at the crystal surface due to non-ideality of an ohmic contact. The tunneling nature of the excess current does not allow to increase the operating bias voltage of the detector with lowering operating temperature because this leads to a significant reduction of the leakage current only at low voltages but not at higher ones. Optimization of the formation of electrical contacts could make it possible to enhance charge collection, however increasing this indicator of detector (for example, up to 99% instead of present 5-6% for the best samples) is complicated because of a slow sub-linear increase in this factor with rising voltage. Calculations of the charge collection efficiency shows that success is possible by lengthening the charge carrier lifetime in CdTe up to 20-30 microseconds. This obviously will require a decrease in the concentration of deep impurities (defects) in the material that is impossible without addressing the issue of improving the quality of CdTe crystals.

Differential thermal analysis investigation of Cd0.95-xMnxZn0.05Te alloys

Vasylyna Kopach, Oleh Kopach, Petro M. Fochuk, Larysa P. Shcherbak, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Aleksey E. Bolotnikov, Ralph B. James, Brookhaven National Lab. (United States)

Cd0.95-xMnxZn0.05Te with x=0.05-0.25 were synthesized using a double-zone furnace and elemental starting materials. The melting Tm and crystallization Ts temperatures of Cd0.95-xMnxZn0.05Te alloys were determined by differential thermal analysis. The melting-crystallization rate was 5 and 10 K/min with a melt dwell time of 1, 10, 20 and 30 min. Experimental results showed that the melting temperature Tm decreased with increasing "x", and the crystallization temperature Ts increased with increasing "x". The crystallization rate dependencies vs. melt's crystallization temperature were studied. In most cases they decreased with the rise of the crystallization temperature, while the crystallization temperature decreased with decreasing melt dwell time. New results on this alloy will be presented.

8852-51, Session PWed

New neutron detector by using semiconductor BGaN

Katsuhiro Atsumi, Kosugi Naohumi, Aki Miyake, Hidenori Mimura, Yoku Inoue, Toru Aoki, Takayuki Nakano, Shizuoka Univ. (Japan)

Neutron imaging technology is expected as a new tool for non-destructive inspection system for high penetration into heavy metals. Therefore, a high speed and high resolution neutron detector is required for the neutron imaging technique. We have suggested a neutron detector by using semiconductor BGaN. We have considered BGaN which was an alloy of BN and GaN as having the sensitivity for the neutron, because the B atom which is able to capture neutron is contained in BGaN. Due to its poor gamma-rays sensitivity, GaN is used to distinguish neutrons from the background gamma-rays. In this work, we fabricated crystalline BGaN and we investigated its neutron detection properties.

BGaN was grown by metal organic vapor phase epitaxy (MOVPE) using the following precursors: trimethylgallium (TMG), triethylboron (TEB) and NH3 for Ga, B and N, respectively. The epitaxial films structure consisted in a GaN buffer layer and a BGaN layer onto a c-plane Al2O3 substrate.

Radiation detection properties were evaluated using the depletion layer formed by applying reverse bias voltage for the Schottky contact (Au/BGaN). Under neutron irradiation, the generated electrons are detected as electron signal. As a result, we confirmed that electrons were generated at the depletion layer for neutron irradiation. This was the detection signal for alfa-ray which are converted into neutrons by B atoms.

We can conclude that our proposed BGaN system can be successfully used as a neutron detector.

8852-52, Session PWed

Characterization of CdTe and (CdZn)Te detectors with different metal contacts

Jakub Pekarek, Eduard Belas, Roman Grill, Stepan Uxa, Charles Univ. in Prague (Czech Republic); Ralph B. James, Brookhaven National Lab. (United States)

CdTe and (CdZn)Te are very promising materials for room temperature X-ray and gamma-ray detectors with high charge collection efficiency (CCE). The amount of collected charge strongly depends on the internal electric field. The lower the electric field the less photo-generated carriers are collected as they are subject to trapping. One of the main problems of preparation of high performance detectors is still the formation of long-term stable contacts resulting in high charge collection efficiency with the absence of detector polarization. Detectors with ohmic contacts exhibit linear I-V characteristics and constant internal electric field without significant polarization. Detectors with one Schottky contact exhibit distortion of the internal electric field and enhanced polarization.

In this work various metal contacts (Au, In and Pt) with different methods of deposition (electroless deposition and evaporation) are prepared on the same detector and the I-V characteristics and transient-current technique (TCT) are used to characterize the quality of the contacts and spatial distribution of the internal electric field. TCT measurements were performed using a current-sensitive preamplifier and a broadband digital oscilloscope. Utilization of different metals enables us to prepare both ohmic and blocking (Schottky) contacts. 241Am ∞-particles with energy of 5.49 MeV were used to create electron-hole pairs close to the cathode. After processing of the recorded pulses the collected charge, carrier mobilities and the inner electric field distribution are evaluated. All measurements are compared with the CCE measurements using alpha particles and the single carrier Hecht equation.

8852-53, Session PWed

Raman analysis of Zn(1-x)Mn(x)Te polycrystalline films

Oleksii Klymov, Denys Kurbatov, Anatoliy S. Opanasyuk, Sumy State Univ. (Ukraine); Volodymyr V. Kosyak, The Univ. of Utah (United States); Oleh Kopach, Petro M. Fochuk, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Aleksey E. Bolotnikov, Ralph B. James, Brookhaven National Lab. (United States)

Zn1-xMnxTe solid solutions have attracted much attention as a promising material for applications in microelectronics due to their unique photoluminescence, magnetic and magneto-optical properties. However, even basic properties of Zn1-xMnxTe, such as optical and structural parameters, have not been studied systematically.

In this study Zn1-xMnxTe solid solution thin films were deposited on glass substrates by a close-spaced vacuum sublimation technique (CSVS) under the following growth conditions: evaporator temperature was 1073 K; substrate temperature was varied in the range from 423 to 823 K. A high-purity Zn1-xMnxTe powder (10% Mn concentration) was used as a charge for the evaporation. The Raman spectroscopy was performed by a Witec Alpha SNOM confocal microscope with 532-nm laser excitation at room temperature within the frequency range of 100-900 sm-1.

A number of intense lines at 176.5, 206, 416 and 621 cm-1 were observed in the Raman spectra. These lines were interpreted according to reference data as 1TO, 1LO, 2LO, and 3LO phonon modes. The presences of several phonon replicas in the Raman spectra confirm high crystal quality of the samples. The Mn concentration was estimated according to the shift in peak position in Raman spectra of the Zn1-xMnxTe films as compared with pure ZnTe. These results were also compared with the results obtained by energy dispersive X-ray analysis.

8852-54, Session PWed

The electrical properties of Al-doped CdTe crystals

Petro M. Fochuk, Yevgen Levchuk, Andriy I. Kanak, Oleh Kopach, Oleh Panchuk, Z. I. Zakharuk, Igor Nakonechnyj, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Igor Terzin, Vitaliy K. Komar, Institute for Single Crystals (Ukraine); Vladimir E. Kutny, Alexandr V. Rybka, National Science Ctr. Kharkov Institute of Physics and Technology (Ukraine); Yevhen Nykoniuk, National Univ. of Water Management and Natural Resources Use (Ukraine); Aleksey E. Bolotnikov, Ralph B. James, Brookhaven National Lab. (United States)

The behavior of aluminum dopants in II-VI compounds is similar to indium, and both of them can be used to obtain high-resistivity material for Cd(Zn)Te detectors. To understand better the influence of Al dopants on CdTe electrical properties, three ingots with different Al content (10^17-10^19 atoms/cm3) were grown by the Bridgman method. The ingots were cut into wafers, polished and etched. I-V curves and IR images were measured for every wafer. The dependences between the resistance and wafer location in the ingots were determined. The maximal transmittance and resistance were determined in the wafers from the ingot with Al content in the melt of approximately 5x10^18 atoms/cm^3.

8852-55, Session PWed

Detectors of ionizing radiation on the base of surface-barrier Ni-CdZnTe-Ni structure

Valery M. Sklyarchuk, Petro M. Fochuk, Zinajida I. Zakharuk, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Roman

Grill, Charles Univ. in Prague (Czech Republic); Vladimir E. Kutny, Alexandr V. Rybka, Dmitrij Nakonechny, Alexandr A. Zakharchenko, National Science Ctr. Kharkov Institute of Physics and Technology (Ukraine); Yevhen Nykoniuk, National Univ. of Water Management and Natural Resources Use (Ukraine); Aleksey E. Bolotnikov, Ralph B. James, Brookhaven National Lab. (United States)

One of the ways to improve the charge collection in semiconductor X- and gamma-ray detectors is by increasing the electric-field strength. The limiting factor in this case is the amount of leakage current. It is possible to reduce it by forming a rectified Schottky contact instead of an Ohmic one. That allows the creation of a depletion layer in the semiconductor with an electrical resistance that is much larger than the bulk resistivity. In this case, the electromotive intensity increases 10-100 times. A surface-barrier structure on a semi-insulating Ni-CdZnTe-Ni crystal (n-type) with a resistivity of 10^10 Ohm-cm at room temperature was formed. The leakage current was measured to be less than 3 nA at 1500 V. Results on the properties of this detector structure will be discussed.

8852-56, Session PWed

Three-energy radiography method for uniformity control of composite materials including components with different effective atomic numbers

Volodymyr D. Ryzhikov Sr., Oleksandr D. Opolonin, Boris V. Grinyov, Serhiy M. Galkin, Olena K. Lysetska, Evgeniy F. Voronkin, Institute for Scintillation Materials (Ukraine); Sergiy A. Kostyukevych, V. Lashkaryov Institute of Semiconductor Physics (Ukraine)

A receiving-detecting circuit has been developed on the basis of “scintillator-photodiode” detector array with improved spatial resolution.

Tests of the receiving-detecting circuit have been carried out, obtaining shadow X-ray images for evaluation of characteristics of digital radiographic systems for non-destructive testing on its base.

Using high precision of positioning of the inspected object movement mechanism, one can successively obtain three images at three different anode voltages and different filtration conditions with subsequent combination of the three images obtained in different energy ranges.

Using this method, we have obtained three-energy X-ray images of silicon carbide plates impregnated with silicon used for fabrication of bullet-proof vests.

Non-uniform character of impregnation was noted, which substantially affects mechanical strength of the plates. Basic relationships were determined for reconstruction of the absorption coefficient energy dependence in three-energy radiography.

Using a three-coordinate RGB identification palette, differences in the effective number of different plates could be noted.

The three-energy image shows that it is higher amount of silicon, with its atomic number higher as compared with silicon carbide, that enhances the blue component of the RGB palette..

The obtained results lead to conclusion that three-energy radiography can be also used for studies of other multi-component and composite materials if their constituents have even small differences in the values of effective atomic number. Preliminary estimates show that the accuracy of detection of discrepancies is better than 10% for materials with Zeff ? 7.

8852-57, Session PWed

Gamma-ray nonvolatile sensor comparison between SONOS and SOTOS capacitor device

Wen-Ching Hsieh, Minghsin Univ. of Science and Technology (Taiwan); Hao-Tien D. Lee, ETOMS Electronics Corp. (Taiwan); Fuh-Cheng Jong, Southern Taiwan Univ. of Technology (Taiwan); Shich-Chuan Wu, National Nano Device Labs. (Taiwan)

The silicon-oxide-nitride-oxide-silicon (SONOS) and silicon-oxide-TEOS-oxide-silicon (SOTOS) capacitor devices can be candidates for nonvolatile gamma radiation sensors. In case of SONOS and SOTOS gamma radiation sensors, the gamma ray radiation induces significant decrease of threshold voltage. The changes of threshold voltage for SONOS and SOTOS after gamma ray expose can be correlated to the dose of gamma ray exposure as well. In this paper, the performance for SONOS and SOTOS capacitor type gamma ray sensor were compared. The SONOS capacitor device with ONO gate dielectric in this study has demonstrated the better feasibility for gamma ray dosimeter application.

EXPERIMENTAL

In this study, two kind of SIS gate dielectric SiO2- Si3N4- SiO2 (ONO) and SiO2- TEOS- SiO2 (OTO) were compared. We use Silane CVD SiO2-CVD Si3N4- Thermal SiO2 for ONO gate dielectric and Silane CVD SiO2-CVD TEOS- Thermal SiO2 for OTO gate dielectric. The thickness of gate dielectric for O-N-O/O-T-O structure is 50Å-200Å-50Å /50Å-200Å-50Å. In this paper, the changes of threshold voltage between SONOS & SOTOS after Gamma ray expose were compared. To write data on these SONOS and SOTOS capacity devices, gamma radiation was exposed and a positive gate voltage was applied on these SONOS and SOTOS capacity devices simultaneously. For the data read, the change of gate threshold voltage in this case can be correlated to the exposure dosage of Gamma radiation as well. These trapped charges can be always accumulated in gate dielectric layer, so dose record can’t be destroyed by data write and read. For the dosage data erase, data in these SONOS and SOTOS capacity devices can be erased to original null state by opposite charges injection.

RESULTS AND DISCUSSIONS

As illustrated in figure 5 it can be seen that the capacity to voltage curves (C-V curve) of SONOS shifted far to the left after 10 Mrad gamma ray irradiation. This implies that gamma ray radiation induces a significant decrease of threshold voltage for SONOS. The amount of decrease of threshold voltage is about 2 volts. It is considered that the change is due to significant increase of positive trapped charges in the gate dielectric ONO layer after gamma ray irradiation. From figure 6, it also can be seen that the capacity to voltage curves (C-V curve) of SOTOS shifted to the left after 10 Mrad gamma ray irradiation. The amount of decrease of threshold voltage is up to about 1 volts. The electron-hole pairs are generated throughout the insulation layers, when these SONOS and SOTOS capacity devices structure are irradiated by gamma rays. These free carriers are swept by electric field, and some of them are captured by the charge trap centers, especially at the O-N/O-T interface and S-O interface. As shown in experiment data, the change of threshold voltage for SONOS is more significant than that for SOTOS. The dependencies of threshold voltage shifts on radiation dose in ONO gate dielectric is more significant than the one in OTO gate dielectric. It can be explained that the amount of positive trapped charges in the ONO gate dielectric layer is greater than the one in the OTO gate dielectric layer; so the decrease of threshold voltage for SONOS is more significant than the one for

SOTOS. It is suggested that the amount of hole traps at O-N interface in ONO gate dielectric layer is more than the one in the OTO gate dielectric layer. As illustrated in figure 7 and figure 8, it also can be seen that the gate leakage current of SONOS after gamma irradiation are less than that of SOTOS. From figure 9 and figure 10, it also can be seen that the dependencies of the threshold voltage decrease on gamma radiation dose for SONOS received are more significant than that of SOTOS. The decrease of gate threshold voltage in this case can be correlated to the increase of positive trapped charges in the insulator and the increase of exposure dosage for Gamma radiation as well. As illustrated in Figure 11 and figure 12, It also can be seen that the threshold voltage decay of

SONOS after gamma irradiation is less than that of SOTOS. This capacity device with ONO gate dielectric in this study has demonstrated the better feasibility of using SONOS capacity device for Gamma Ray dosimeter.

Radioluminescence dosimetry by scintillating fiber optics: the open challenges

Ivan Veronese, Marie Claire Cantone, Univ. degli Studi di Milano (Italy); Norberto Chiodini, Univ. degli Studi di Milano-Bicocca (Italy); Cristina De Mattia, Univ. degli Studi di Milano (Italy); Mauro Fasoli, Univ. degli Studi di Milano-Bicocca (Italy); Eleonora Mones, Azienda Ospedaliera Maggiore della Carità (Italy); Anna G. Vedda, Univ. degli Studi di Milano-Bicocca (Italy)

In the last decade, the interest in scintillating fiber optics for ionizing radiation monitoring is constantly increasing. Among the fields of possible applications of these sensors, radiation therapy represents a driving force for the research and development of new devices. In fact, the small dimensions of fiber optics based detectors, together with their real-time response, make these systems extremely promising both in quality assurance measurements of intensity modulated radiotherapy beams, and in in-vivo dosimetry. On the other hand, two specific aspects might represent limiting factors: (i) the "stem effect", that is the spurious luminescence originating as consequence of the irradiation of the light guide, and (ii) the "memory effect", that is the radioluminescence sensitivity increase during prolonged exposition to ionizing radiation, typical of many scintillating materials.

These two issues, representing the main challenges to face for the effective use of scintillating fiber as dosimeters in radiotherapy, were studied considering amorphous silica matrices prepared by sol-gel method and doped with various rare earths (i.e. Ce, Eu and Yb). The origin of the stem effect was investigated by means of spectral measurements of the doped fibers irradiated with X-rays and electrons of different energies, field sizes and orientations. New approaches for removing the stem effect on the basis of the radioluminescent spectral analysis and of optical filtering are presented and discussed. Furthermore, the causes and phenomenology of the memory effect are described, considering also the effect of dose accumulation with different dose rates and energies of ionizing radiation.

Boron selenide semiconductors for thermal neutron counting

Alireza Kargar, Radiation Monitoring Devices, Inc. (United States)

Thermal neutron detectors in planar configuration were fabricated from B2Se3 (Boron Selenide) crystals grown at RMD Inc. All fabricated semiconductor devices were characterized for the current-voltage (I-V) characteristic and neutron counting measurement. Pulse height spectra were collected from 241AmBe (neutron source on all samples), as well as 137Cs and 60Co gamma ray sources. In this study, the resistivity of all crystals is reported and the collected pulse height spectra are presented for fabricated devices. Finally, the neutron detection of the B2Se3 detectors is compared with a standard 3He tube for further verification. Note that, the 241AmBe neutron source was custom designed with polyethylene around the source as the neutron moderator, mainly to thermalize the fast neutrons before reaching the detectors. The B2Se3 devices showed response to thermal neutrons of the 241AmBe source.

Improved CZT detectors: innovative contacts and unique surface treatments

Krishna C Mandal, Ramesh M. Krishna, Sandeep K. Chaudhuri, Univ. of South Carolina (United States)

CZT (Cd0.9Zn0.1Te) gamma radiation detectors are presently the best candidates for room temperature operation. At present, the typical energy resolution of CZT detectors is ~1%, rather than the desired ≤0.5%. To achieve this energy resolution, we have employed bandgap engineered novel amorphous contacting techniques, unique post growth treatment, and surface modifications. The approach involved three innovative pathways to improve the resolution of CZT radiation detectors: (1) implementation of high-barrier Schottky contacts to reduce the leakage current to an acceptable level; (2) post growth annealing treatments to eliminate Te-inclusions, which trap the electrons and limit the signals observed in the external circuitry; and (3) surface passivation by unique surface modifying treatments to passivate electrically active surface states which in turn helps to reduce leakage current. Chemical treatment is a very effective method for passivation of semiconductor surfaces. Sulfides (Na2S, xH2O) and selenides (Na2Se, 9H20) pretreatments of Cd0.9Zn0.1Te have been shown to improve the interface properties of metal (M)/Cd0.9Zn0.1Te significantly. The interface state density as obtained from C-V (1 MHz) measurements was found to reduce to 1.2x10^10 from 4.8x10^10 cm^-2eV^-1after surface treatment. The reduced interface state density resulted in increased photoluminescence intensity. X-ray photoelectron spectroscopy studies revealed the formation of Te-S and Te-Se after sulfide and selenide treatments respectively, which are responsible for better interfacial behavior. Final assessments of the detector performance have been carried out using various radio-isotopes in the energy range of 60-662 keV. The improved CZT detectors are cost-effective and highly efficient, and offered substantial performance advantages.

Characterization of amorphous selenium alloy detectors for x-rays and high-energy nuclear radiation detection

Krishna C. Mandal, Abhinav Mehta, Sandeep K. Chaudhuri, Univ. of South Carolina (United States); Yunlong Cui, Michael Groza, Arnold Burger, Fisk Univ. (United States)

Synthesized amorphous selenium (a-Se) alloy samples have been characterized for room temperature x-rays and high-energy nuclear radiation detector applications. The alloy composition has been optimized to ensure good charge transport properties and detector performance. The synthesis of a-Se (As, Cl) alloys has been carried out by thoroughly mixing zone-refined (ZR) Se (~7N) with previously synthesized a-Se(As) and a-Se(Cl) master alloys (MS). The synthesized alloys have been characterized by x-ray diffraction (XRD), glow discharge mass spectroscopy (GDMS), differential scanning calorimetry (DSC), Fourier transform infra-red spectroscopy (FTIR), x-ray photoelectron spectroscopy (XPS), temperature varying current-voltage (I-V) characteristics, capacitance-voltage (C-V) measurements, and thermally stimulated current measurements (TSC). Raman spectroscopy demonstrated that the a-Se(As) master alloy samples were in metastable monoclinic Se8 states, in which seven vibrational modes are located at 40(41), 59(60), 77, 110, 133, 227(228) and 251(252) cm^-1. However, a-Se(Cl) master alloy samples is in stable form of trigonal structure of Se8, in which two modes at 142 and 234 cm^-1 were found. Both Raman and energy dispersive spectroscopy (EDS) exhibited that a small amount of tellurium (Te) existed in a-Se(As,Cl) master alloy samples. DSC measurements showed that a-Se(Cl) MS and a-Se(As) MS samples have one melting point, located at ~219.6C, whereas a-Se-As (0.52%)-Cl and Se-As(10.2%)-Cl(60 ppm) both possess two melting points, located at 221 and 220.3C respectively. The a-Se alloy plate detectors have been fabricated and tested and the results showed high dark resistivity (10^12

- 10^13 ?-cm), good charge transport properties, and cost-effective large area scalability.

THM-grown CdZnTe detectors

Shariar Motakef, Piotr Becla, Stacy Swider, Krzysztof Becla, Matthew R. Overholt, John Fiala, William Higgins, CapeSym, Inc. (United States)

Growth of CdZnTe at temperatures lower than the melting point temperature of the material offers two major advantages relative to solidification from melt. The first advantage is the increase in the segregation coefficient of most impurities, resulting in lower background impurities in the grown material. The second advantage is the possibility of growing single crystal boules, in contrast to boules produced by solidification from melt which generally contain a number of grains.

We report on growth of CdZnTe by the Travelling Heater Method (THM) method. We have established a repeatable process for growth of single crystals boules. The grown crystals have been subjected to post-growth processing to produce materials for radiation detectors. The detectors have a very low density of small Te precipitates of 1-2 microns in diameter and have high resistivity in the range of 109-1010 ohm-cm. The electron lifetime-mobility of detectors have a mean value of 0.9x10-2 cm2/V, with a variation of +/- 0.3x10-2 cm2/V. The energy resolution of planar detectors at high field strengths is in the range of 1.4-1.7%.

The point defect signature of the produced material has been investigated by Photo Induced Current Transient Spectroscopy. The detectors with superior ut are observed to have low concentration of midgap defects relative to the shallow defects.

This work was supported by US Department of Energy, office NA-22 under competitively awarded contract DE-SC0006440.

Measurement of volatile components in iodine- and chlorine-based starting materials for scintillators and neutron detectors

Stacy Swider, William Higgins, Krzysztof Becla, Shariar Motakef, CapeSym, Inc. (United States)

Alkaline-earth binary and ternary halides can be made into bright scintillators when activated with Eu2+ or Ce3+. However the hygroscopic nature of starting material encourages the formation of oxy-halides and carbonates that ultimately lead to cracking and/or poor scintillation performance in the grown crystal. A similar degradation in structural integrity and performance is observed in CLYC crystals used for neutron and gamma detection. In order to develop protocols to minimize contamination, it is of interest to analyze the starting material for water, carbon dioxide, and other species adsorbed on the surface or contained in the bulk. We report on the evolution of volatile species in SrI2, EuI2, CsCl, LiCl YCl3, and CeCl3 when heated in vacuum. Measurements were made via residual gas analysis (RGA). The experiments consist of heating a small amount of the starting material under vacuum and recording the partial pressure of the evolving gases as the sample temperature is increased. We have observed two distinct regimes. First, release of adsorbed gases such as H2O and CO2 at temperatures up to 400 degC. The second regime coincides with the evaporation of iodine or chlorine, where other elements are released. The incongruent melting points and thermal behavior (dissociation, sublimation) of the binary components also pose considerable process challenges. Released elements vary among the materials studied, but generally include water, carbon dioxide, argon, sulfur, and certain chlorine species. These results provide guidelines for removal of adsorbed gases from the starting material, and suggest a need for stoichiometry control.

This work has been supported by the US Department of Homeland Security, Domestic Nuclear Detection Office, under competitively awarded contracts HSHQDC-11-C-00109, HSHQDC-11-C-00110, and HSHQDC-12-C-00093. This support does not constitute an express or implied endorsement on the part of the Government.

Tests of pixilated CZT detectors with slanted-hole collimators in a compact endocavity gamma camera

Yonggang Cui, Brookhaven National Lab. (United States); Terry Lall, Jim Ionson, Gamma Medical Technologies (Canada); Giuseppe S. Camarda, Anwar Hossain, Ge Yang, Utpal N. Roy, Ralph B. James, Brookhaven National Lab. (United States)

We will discuss test results for a small field-of-view endocavity gamma camera that uses CdZnTe pixilated detectors to detect and image gamma-ray sources. The camera uses collimators with slanted holes to obtain limited 3D imaging. A prototype system for planar imaging has already been developed and clinically evaluated, and a new version of the gamma camera is being assembled capable of providing depth information as well as planar images. A ML-EM method will be used for the 3D image reconstruction. Bench-top data using the prototype system with slanted collimators will be reported for sealed Co-57 sources.

8853-1, Session 1

Dark-count-less x-ray photon counting using a YAP(Ce)-MPPC detector and its application to computed tomography *(Invited Paper)*

Eiichi Sato, Yasuyuki Oda, Iwate Medical Univ. (Japan); Hajime Kodama, Osahiko Hagiwara, Hiroshi Matsukiyo, Akihiro Osawa, Toshiyuki Enomoto, Manabu Watanabe, Shinya Kusachi, The Toho Univ. (Japan); Shigehiro Sato, Akira Ogawa, Iwate Medical Univ. (Japan)

To develop a high-speed energy-dispersive X-ray CT, we performed investigation of dark-count-less X-ray photon counting using a YAP(Ce)-MPPC detector. YAP(Ce) crystal with a decay time of 30 ns is stuck on the light-receiving surface of a multipixel photon counter (MPPC) and covered with an aluminum cap with a 0.2 mm-thick aluminum window. Successively, the detector is shielded using an aluminum case and a BNC connector, and the anode electrode of the MPPC is connected to the ground. The photocurrent from the MPPC was amplified by a high-speed current-voltage amplifier, and the event pulse is sent to a multichannel analyzer (MCA) to measure X-ray spectra. The MPPC was driven in pre-Geiger mode at a bias voltage of the MPPC of 70.7 V. Photon-counting computed tomography (PC-CT) is accomplished by repeated linear scans and rotations of an object, and projection curves of the object are obtained by the linear scan. In the PC-CT, we confirmed energy-dispersive effect with changes in the lower level voltage of the event pulse.

8853-2, Session 1

Energy dispersive photon counting detectors for breast imaging *(Invited Paper)*

William C. Barber, DxRay, Inc. (United States); Jan C. Wessel, Nail Malakhov, Gregor Wawrzyniak, Interon AS (Norway); Neal E. Hartsough, Thulasidharan Gandhi, DxRay, Inc. (United States); Einar Nygard, Interon AS (Norway); Jan S. Iwanczyk, DxRay, Inc. (United States)

We report on our efforts toward the development of silicon (Si) strip detectors for energy-resolved clinical breast imaging. Typically, x-ray integrating detectors based on scintillating cesium iodide CsI(Tl) or amorphous selenium (a-Se) are used in most commercial systems. Recently, mammography instrumentation has been introduced based on photon counting silicon Si strip detectors. Mammography requires high flux from the x-ray generator, therefore, in order to achieve energy resolved single photon counting, a high output count rate (OCR) for the detector must be achieved at the required spatial resolution and across the required dynamic range for the application. The required performance in terms of the OCR, spatial resolution, and dynamic range must be obtained with sufficient field of view (FOV) for the application thus requiring the tiling of pixel arrays and scanning techniques. Room temperature semiconductors, operating as direct conversion x-ray sensors, can provide the required speed when connected to application specific integrated circuits (ASICs) operating at fast peaking times with multiple fixed thresholds per pixel, provided that the sensors are designed for rapid signal formation across the x-ray energy ranges of the application at the required energy and spatial resolutions. We present our methods and results from the optimization of prototype detectors based on Si strip structures. We describe the detector optimization and the development of ASIC readout electronics that provide the required spatial resolution, low noise, high count rate capabilities and minimal power consumption.

8853-3, Session 1

Characteristics of a ceramic-substrate x-ray diode and its application to computed tomography

Manabu Watanabe, The Toho Univ. (Japan); Eiichi Sato, Iwate Medical Univ. (Japan); Hajime Kodama, Osahiko Hagiwara, Hiroshi Matsukiyo, Akihiro Osawa, Toshiyuki Enomoto, Shinya Kusachi, The Toho Univ. (Japan); Shigehiro Sato, Toho Univ. School of Medicine (Japan); Akira Ogawa, Iwate Medical Univ. (Japan)

X-ray photon counting was performed using a silicon X-ray diode (Si-XD) at a tube voltages ranging from 40 to 110 kV. The Si-XD is a high-sensitivity Si photodiode selected for detecting X-ray photons, and X-ray photons are directly detected using the Si-XD without a scintillator. Photocurrent from the diode is amplified using charge-sensitive and shaping amplifiers. To investigate the X-ray-electric conversion, we performed the event-pulse-height (EPH) analysis using a multichannel analyzer (MCA). Using an americium-241 (241Am) ?-photon source with an energy of 59.5 keV, the photon count substantially increased with decrease in the channel number of the MCA. Photon-counting computed tomography (PC-CT) is accomplished by repeated linear scans and rotations of an object, and projection curves of the object are obtained by the linear scan. In PC-CT at a constant tube voltage, we observed image-contrast variations with changes in lower-level voltage of the event pulse using a comparator.

8853-4, Session 1

Investigation of x-ray photon counting using a silicon-PIN diode and its application to energy-dispersive computed tomography

Hajime Kodama, The Toho Univ. (Japan); Eiichi Sato, Michiaki Sagae, Iwate Medical Univ. (Japan); Osahiko Hagiwara, Hiroshi Matsukiyo, Akihiro Osawa, Toshiyuki Enomoto, Manabu Watanabe, Shinya Kusachi, The Toho Univ. (Japan); Shigehiro Sato, Toho Univ. School of Medicine (Japan); Akira Ogawa, Iwate Medical Univ. (Japan)

X-ray photon counting was performed using a readymade silicon-PIN X-ray diode (Si-PIN-XD) at tube voltages ranging from 50 to 100 kV. The Si-PIN-XD is a high-sensitivity Si-PIN photodiode selected for detecting X-ray photons, and X-ray photons are directly detected using the 100 MHz Si-PIN-XD without a scintillator. Photocurrent from the diode is amplified using charge-sensitive and shaping amplifiers. Using a multichannel analyzer (MCA), X-ray spectra at a tube voltage of 100 kV could easily be measured. The photon-counting computed tomography (PC-CT) is accomplished by repeated linear scans and rotations of an object, and projection curves of the object are obtained by the linear scan. In the PC-CT, we confirmed the energy-dispersive effect with changes in lower-level voltage of the event pulse using a comparator.

Design and characterization of low-noise multichannel front-end readout ASICs dedicated to CZT detectors for biomedical imaging applications *(Invited Paper)*

Wu Gao, D. Gao, T. Wei, B. Gan, H. Zeng, R. Zheng, Y. Hu, Northwestern Polytechnical Univ. (China)

This talk is on the design techniques of low noise multi-channel front-end readout application-specific integrated circuits (ASICs) for biomedical imaging applications such as PET, SPECT, CT etc. In this presentation, three parts will be included. Firstly, research progresses in analog signal readout and processing, A/D converters and digital signal pre-processing techniques will be given. Moreover, the test results of our four developed ASICs will be presented and discussed in the second part. Thirdly, the conclusions and prospects of low-noise front-end readout ASICs will be described.

8853-8, Session 2

A SPECT imager with synthetic collimation

Ronan J. Havelin, National Univ. of Ireland, Galway (Ireland); Harrison H. Barrett, College of Optical Sciences, The Univ. of Arizona (United States); Brian W. Miller, Pacific Northwest National Lab. (United States); Lars R. Furenlid, College of Optical Sciences, The Univ. of Arizona (United States); J. Mary Murphy, Mark J. Foley, National Univ. of Ireland, Galway (Ireland)

A multi-pinhole SPECT system was designed to produce synthetic-collimator images of a small field of view. A focused multi-pinhole collimator was constructed using rapid-prototyping and casting techniques. The collimator projects the center of the field of view through forty-six pinholes when the detector is adjacent to the collimator. The detector is then moved further from the collimator to increase the magnification of the system. The amount of pinhole projection overlap increases as the system magnification increases. There is no rotation in the system; a single tomographic angle is used in each system configuration. The complexity of the multi-pinhole collimator requires the use of an iterative reconstruction algorithm. To reconstruct an activity distribution, iterative algorithms require an accurate model of the system response. A low-resolution system response is measured by translating a point source through a coarse grid encompassing the field of view, for each configuration. The pinhole projections are individually identified and associated with their respective apertures. A 2D elliptical Gaussian model is applied to the pinhole projections on the detector. These coefficients are associated with the object-space location of the point source, and a finer system matrix is interpolated. The interpolation is validated through comparison with a small, high-resolution system matrix that is experimentally measured. The system is also validated experimentally with a hot-rod phantom. The average spatial resolution of the system along each axis is estimated using the Fourier crosstalk matrix.

Accurate system modeling of positron emission mammography

Bing Bai, The Univ. of Southern California (United States); Weidong Luo, Naviscan, Inc. (United States); Magnus Dahlbom, Univ. of California, Los Angeles (United States)

Objectives

A high-resolution positron emission mammography (PEM) scanner has been developed using two stationary panel detector heads. Due to its unique geometry, the point spread function (PSF) of the system is highly non-uniform. It has been shown from other PET systems that iterative reconstruction techniques using accurate system modeling are able to significantly improve image quality. Our aim of this study is to develop accurate system model of the PEM scanner with fast implementation for clinical PEM scans.

Methods

The Naviscan PEM scanner has been described previously [1]. We use GATE to simulate the system. A low activity point source is positioned inside the field of view (FOV). The source is moved on a grid to measure the PSF at different locations. Due to the symmetry of the scanner, the point source only needs to cover 1/8 of the FOV. A parametric model will be developed for fast implementation, similar to those used in PET scanners [2].

Results

GATE simulation results show that the PSF varies dramatically as the point source is moved across the FOV. The attached figure shows the distribution of counts of LORs in coincidence with a fixed crystal on the opposite panel. The top figure has the point source at the center of FOV, while for the bottom figure the source is moved 9mm toward one panel.

Conclusions

Simulated PSF of PEM scanner shows large variations, which need to be taken into account in reconstruction. We will develop fast implementations of accurate system model based on the GATE simulation. Results will be presented at the conference.

Applying high frame-rate digital radiography and dual-energy distributed-sources for advanced tomosynthesis *(Invited Paper)*

Gil Travish, Univ. of California, Los Angeles (United States); Felix J. Rangel, Mark A. Evans, Kristin Schmiedehausen M.D., Radius Diagnostics Research, Inc. (United States)

Conventional radiography uses a single point x-ray source with a fan or cone beam to visualize various areas of the human body. An imager records the transmitted photons—historically film and now increasingly digital radiography (DR) flat panel detectors—followed by optional image post-processing. Tomosynthesis adds the ability to recreate quasi-3D images from a series of 2D projections. These exposures are typically taken along an arc or other path; and, tomosynthesis reconstruction is used to form a three-dimensional representation of the area of interest. Dual energy (two color) radiography adds the ability to enhance or “eliminate” structures based on their different attenuation of well-separated end-point energies in two exposures. These advanced capabilities come at a high cost in terms of complexity, imaging time, capital equipment, space, and potentially reduced image quality due to motion blur.

Recently, the prospect of creating x-ray sources, which are composed of arrays of micro-emitters has been put forward. These arrays offer a flat-panel geometry and may afford advantages in fabrication methodology, size and cost. They also facilitate the use of the dual energy technology. Here we examine the possibility of using such an array of x-ray sources combined with high frame-rate (~kHz) DR detectors to produce advanced medical images without the need for moving gantries or other complex motion systems. Combining the advantages of dual energy imaging with the ability to determine the relative depth location of anatomical structures or pathological findings from imaging procedures that are nearly identical to general radiology, should prove to be a powerful diagnostic tool. In addition to the requirements for the desired detector, we will present simulation results and use cases that would benefit from the capabilities of this modality.

8853-16, Session 4

A new apparatus of infrared videopupillography for monitoring pupil size

(Taiwan)

People usually neglect the symptoms of glaucoma because they are not usually very obvious. We diagnosed or tracked glaucoma by the intraocular pressure (IOP) generally because IOP is one of the physiology parameters that are associated with glaucoma. This paper propose a platform to study the correlation between glaucoma and the physiology parameter, the pupil size. A device is instrumented to monitor the pupil size in an attempt to bypass the direct IOP measurement. The portable pupil metering device of first generation contains a camera, a beam splitter, the visible-light LEDs for stimulating the eyes, and the infrared LEDs for lighting the eyes. It can be modulated to focus on different eye locations, and can be mounted on an eyeglass frame. Computations correlate eye shapes with pupil size changes. Some drawbacks of first generation device are the large volume, heavy weight, some LED light spot, and less modulating dimensions for the camera focusing. Therefore, the portable pupil metering device of second generation are designed as a smaller and lighter device with more modulating dimensions, and will seek the approach to solve the LED light spots, just like the diffusor. We hope the measurement resulted with the pupil meter proposed in this paper can help measure the pupil contraction and correlate with different eye diseases in future.

Efficient image acquisition design for a cancer detection system

Dung C. Nguyen, MIAO IC Design, LLC (United States); Janet M. Roveda, MIAO IC Design, LLC (United States) and The Univ. of Arizona (United States); Marisa H. Borders M.D., Kimberly A. Fitzpatrick M.D., Hans N. Roehrig, The Univ. of Arizona (United States)

Modern imaging modalities, such as Computed Tomography (CT), Digital Breast Tomosynthesis (DBT) or Magnetic Resonance Tomography (MRT) are able to acquire volumetric images with an isotropic resolution in micrometer (um) or millimeter (mm) range. When used in interactive telemedicine applications, these raw images need a huge storage unit, thereby necessitating the use of high bandwidth data communication link. To reduce the cost of transmission and enable archiving, especially for medical applications, image compression is performed. Recent advances in compression algorithms have resulted in a vast array of data compression techniques, but because of the characteristics of these images, there are challenges to overcome to transmit these images efficiently. In addition, the recently studies raise the low dose mammography risk on high risk patient. Our preliminary studies indicate that by bring the compression before the analog-to-digital conversion (ADC) stage is more efficient than other compression techniques after the ADC. The linearity characteristic of the compressed sensing and ability to perform the digital signal processing (DSP) during data conversion open up a new area of research regarding the roles of sparsity in medical image registration, medical image analysis (for example, automatic image processing algorithm to efficiently extract the relevant information for the clinician), further X-ray dose reduction for mammography, and contrast enhancement.

8854-1, Session 1

Dual gamma/neutron directional elpasolite detector *(Invited Paper)*

Paul P. Guss, Sanjoy Mukhopadhyay, National Security Technologies, LLC (United States)

Some applications, particularly in homeland security, require detection of both neutron and gamma radiation; this is accomplished by combining two detectors registering neutrons and gammas separately. We have investigated a new type of neutron/gamma (n/g) directional detection capability. We explored a new class of scintillator, Ce-doped Elpasolites such as Cs2LiYCl6:Ce (CLYC), Cs2LiLaCl6:Ce (CLLC), Cs2LiLaBr6:Ce (CLLB), and Cs2LiYBr6:Ce (CLYB). These materials provide energy resolution as good as 2.9% at 662 keV (FWHM), which is better than that of NaI:Tl. Because they contain 6Li, Elpasolites can also detect thermal neutrons. In the energy spectra, the full energy thermal neutron peak appears near or above 3 GEEn MeV. Thus, very effective pulse height discrimination is possible. In addition, the core-to-valence luminescence (CVL) provides Elpasolites with different temporal responses under gamma and neutron excitation, and, therefore, may be exploited for effective pulse shape discrimination. For instance, the CLLC emission consists of two main components: (1) CVL spanning from 220 to 320 nm and (2) Ce emission found in the range of 350 to 500 nm. The former emission is of particular interest because it appears only under gamma excitation. It is also very fast, decaying with a 2 ns time constant. The n/g discrimination capability of Elpasolite detectors may be optimized by tuning the cerium doping content for maximum effect on n/g pulse shape differences. The resulting Elpasolite detectors have the ability to collect neutron and gamma data simultaneously, with excellent discrimination. Further, an array of four of these Elpasolite detectors will perform directional detection in both the neutron and gamma channels simultaneously.

Ca2+-doped CeBr3 scintillating materials

Paul P. Guss, National Security Technologies, LLC (United States); Michael E. Foster, Bryan M. Wong, F. Patrick Doty, Sandia National Labs. (United States); Kanai S. Shah, Michael R. Squillante, Urmila Shirwadkar, Rastgo H. Hawrami, Josh P. Tower, Radiation Monitoring Devices, Inc. (United States); Ding Yuan, National Security Technologies, LLC (United States)

Despite the outstanding scintillation performance characteristics of cerium tribromide (CeBr3) and cerium-activated lanthanum tribromide (LaBr3:Ce), their commercial availability and application are limited due to the difficulties of growing large, crack-free single crystals from these fragile materials. Aliovalent doping was employed to strengthen CeBr3 in an effort to ease crystal growth constraints and improve ingot yields. One divalent dopant (Ca2+) was investigated to determine if it could strengthen CeBr3 without negatively impacting scintillation performance. Ingots containing nominal concentrations of 1.9% of the Ca2+ dopant were grown. Preliminary scintillation measurements are presented for this aliovalently doped scintillator. Ca2+-doped CeBr3 exhibited little or no change in the peak fluorescence emission for 371 nm excitation for CeBr3. The structural, electronic, and optical properties of CeBr3 crystals were investigated using the density functional theory within generalized gradient approximation. The calculated lattice parameters are in good agreement with the experimental data. The energy band structures and density of states were obtained. The optical properties of CeBr3, including the dielectric function, were calculated.

Real-time active cosmic neutron background reduction methods *(Invited Paper)*

Sanjoy Mukhopadhyay, Paul P. Guss, Richard J. Maurer, Ronald S. Wolff, Stephen E. Mitchell, National Security Technologies, LLC (United States)

Neutron counting using large arrays of proportional counters from an aerial system or in a maritime environment suffers from the background counts from the primary cosmic neutrons and secondary neutrons caused by cosmic ray?induced mechanisms such as spallation and charge-exchange reaction. We have attempted two different methods to reduce the cosmic neutron background in real time. As a first step, both methods utilized shielding materials with high concentrations (up to 30% by weight) of neutron-absorbing elements, such as natural boron, to remove the low-energy neutron flux from cosmic neutrons. The goals of the first method were to design, prototype, and test an up-looking plastic scintillator to tag the cosmic neutrons and then create a logic pulse of a fixed time duration (~120 micro-s) to block the data taken by the neutron

counter (pressurized 3He tubes). The second method examined the time correlation between the arrival of two successive neutron signals to the counting array and calculated the excess of variance (Feynman variance) in the neutron count distribution from Poisson distribution. The dilution of this variance from cosmic background values ideally would signal the presence of man-made neutrons. The first method was successful in tagging the neutrons in the cosmic ray flux and preventing them from being counted in the 3He tube array by electronic veto. The second method has successfully derived an empirical relationship between the percentile non-cosmic component in a neutron flux and the Feynman variance Y2F of the measured neutron count distribution.

Preparing for the 100-megapixel detector: reconstructing a multi-terabyte computed-tomography dataset

Laurel J. Orr, Edward S. Jimenez, Sandia National Labs. (United States)

Although there has been much progress in applying GPU-technology to Computed-Tomography reconstruction algorithms, much of the work has concentrated on optimizing reconstruction performance for smaller medical-scale datasets. Industrial CT datasets can vary widely in size and number of projections. With the new advancements in high resolution cameras, it is entirely possible that the Industrial CT community may soon have the need to pursue a 100-megapixel (10Kx10K pixels) detector for CT applications. Simply adding extra GPUs would not be an option as memory and storage bottlenecks would result in prolonged periods of GPU downtime. Additionally, current reconstruction algorithms (CPU and GPU-based) would not be sufficient due to the various bottlenecks in the processor hardware. Past work has shown that CT reconstruction is an irregular problem on a GPU due to the massively parallel environment. This work proposes a high-performance multi-GPU modularized approach to reconstruction such that computation, memory transfers, and disk I/O can occur in parallel while accommodating the irregular nature of the computation kernel. Our approach utilizes a dynamic MIMD-type of architecture in a hybrid environment of CUDA and Open-MP. The modularized approach showed an improvement in load-balancing and performance such that a 1 trillion voxel volume was reconstructed from 10K 100-Megapixel projections in less than a day.
Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energys National Nuclear Security Adminis- tration under contract DEAC04-94AL85000.

High-rate beta decay measurement at Omega and NIF *(Invited Paper)*

Andi Klein, Robert Aragonez, Melissa Boswell, Malcolm Fowler, Jeffrey R. Griego, Gary P. Grim, Robert Rundberg, Carl H. Wilde, Jeremy Wilhelmy, Los Alamos National Lab. (United States)

One of the most challenging problems in high-energy-density physics is the calculation of turbulent mixing in compressible and converging flows with thermonuclear (TN) energy release. This mixing originates from hydrodynamical instabilities at material interfaces, which are created by laser driven ablation and compression of D-T capsules at Omega and NIF. To study the underlying physics, the shell gets doped with different material, which will be activated through either the 14 MeV neutrons of charged particles. We have developed a detector system, which is capable to measure energy and decay time of the resulting Beta Decay, in a high rate environment. We are using a segmented scintillator telescope, which has an energy resolution of 400 keV and can handle rates up to 4 MHz. Th signals from the PMTs are recorded by 4 channel digitizer scopes and a fast 8 channel digitizer card. We will also present results on a new digitizer prototype with higher throughput.

Testing of the Gamma Ray Diagnostic System at Los Alamos Microtron and Omega Laser

Daniel Lemieux, College of Optical Sciences, The Univ. of Arizona (United States)

Abstract: The National Ignition Facility at Lawrence Livermore National Laboratories has had a need for a Gamma Ray Diagnostic System to analyze the ablator symmetry. Ongoing work at the University of Arizona and Los Alamos has resulted in a prototype imaging system. This system has been tested using a Bremsstrahlung Microtron source at Los Alamos National Laboratory. This test demonstrates the proof of concept of the systems ability to image MeV gammas. Further work on characterizing the system will take place at the Omega Laser at the University of Rochester by way of hard x-rays.

Dual view x-ray inspection system based on FPGA technique *(Invited Paper)*

Zhiwen Lu, Ning Song Peng, Shanghai Gaojing Metal Detector Instrument Co., Ltd. (China)

X-ray inspection technique for foreign objects in food products can determine the presence of contaminants within the product and reject by using image process and pattern recognition technique on the X-ray transmission images. This paper presents dual view X-ray inspection system based on FPGA technique for foreign objects in food jar via analyzing the weak point of the traditional single view X-ray inspection technique. In addition, a prototype with the new technique is developed in accordance with glass splinters detection and rejection within the food jar (glass jar especially) which is a typical tickler. This paper describes the rejection control system based on FPGA technique and the concrete realization method, with which, the prototype can detect the NG(not good) jars with 3mm diameter foreign splinter and continuously reject them accurately at the speed of 40m/min. This system effectively reduces the mistake rate and miss rate for food products checking, and greatly improves the production efficiency simultaneously. Finally the actual test results of this prototype are given.

Key words: FPGA technique; dual view X-ray; X-ray machine; X-ray Inspection technique

Trends and Challenges in Open Source Software

Stephen Aylward, Kitware, Inc. (United States)

Over the past decade, the field of medical image analysis research has undergone a rapid evolution. It was a collection of disconnected efforts that were burdened by mundane coding and file I/O tasks. It is now a collaborative community that has embraced open-source software as a shared foundation, reducing mundane coding and I/O burdens, promoting replicable research, and accelerating the pace of research and product development. This talk will review the history and current state of open-source software in medical image analysis research, will discuss the role of intellectual property in research, and will present emerging trends and technologies relevant to the growing importance of open-source software.

8855-1, Session 1

Production, detection, and manipulation of scalar vortex and radially polarized beams *(Invited Paper)*

Ignacio Moreno, Univ. Miguel Hernández de Elche (Spain)

In this work we will describe techniques for the generation of vortex beams, including vortex generating diffraction gratings and diffractive lenses, as well as some possible applications in optical image processing. We will then analyze the description of radially polarized beams in terms of superposition of such vortex beams. We will present some methods for the production of radially polarized light, that include patterned linear polarizers, specially designed liquid crystal devices and spatial light modulators (SLMs). We will analyze the manipulation of this radial polarization by means of wave-plates, in order to obtain other non-standard spatially variant polarized light beams. Theoretical analysis will be presented based on the Jones matrix theory, and experimental results will be included for all cases.

8855-2, Session 1

Optical asymmetric cryptosystem using polarized light

Sudheesh K. Rajput, Naveen K. Nishchal, Indian Institute of Technology Patna (India)

We propose an optical asymmetric image encryption scheme using phase-truncated Fourier transform and polarization encoding. An image bonded with a random phase mask is Fourier transformed and then the spectrum is amplitude- and phase- truncated. The phase-truncated value is encrypted using the concept of polarized light in which two independent optical plane waves are used. The first plane wave illuminates input image and is encoded into a given state of polarization. The second plane wave illuminates an intensity key image and is encoded into another state of polarization. Thus obtained two waves are mixed to obtain first level of encryption. The resultant is then passed through a matrix of linear polarizer (pixilated polarizer), to obtain second level of encryption. For decryption, the encrypted image is passed through the same pixilated polarizer at exact angles. Finally, the decrypted image is obtained by computing Fourier transform of the retrieved phase-truncated value bonded with amplitude-truncated value.

The proposed method offers flexibility in the encryption key design. Due to amplitude- and phase- truncation process the designed keys are asymmetric in nature. We also checked the immunity against special attack if polarization keys are unknown. Results of numerical simulation are presented in support of the proposed scheme.

8855-3, Session 1

Study of the modulation capabilities of parallel aligned liquid crystal on silicon displays

Andrés Márquez, Univ. de Alicante (Spain); Francisco J. Martinez-Verdu, Univ. de Alicante (Spain); Sergi Gallego, Manuel Ortuño, Jorge Francés Monllor, Augusto Beléndez, Inmaculada Pascual, Univ. de Alicante (Spain)

Among the existent technologies of spatial light modulator devices, parallel aligned liquid crystal on silicon displays (PA-LCoS) have found wide acceptance. They are especially interesting since they provide phase-only modulation with no coupling of amplitude modulation. Optimal use of these devices requires proper calibration of their modulation capabilities in order to minimize some degradation effects found in the literature, such as flicker or anamorphic and frequency dependent modulation. In this work we apply calibration techniques developed in our lab, basically the classical linear polarimeter adapted to be able to take into account the existence of flicker. This method enables to obtain both the average retardance and a good estimation of the magnitude of the phase fluctuation when flicker is present. Various addressing formats are considered together with variations in the magnitude of the applied voltages in order to amplify the retardance dynamic range and to enhance linearity in the device. Finally some applications in diffractive optics will be given.

8855-4, Session 1

Cardiac rate detection method based on the beam splitter prism

Lei Yang, Xiaohua Liu, Ming Liu, Yuejin Zhao, Liquan Dong, Ruirui Zhao, Xiaoli Jin, Beijing Institute of Technology (China)

A new cardiac rate measurement method is proposed. Through the beam splitter prism, the common optical system of the transmitting and receiving signals is achieved. By the focusing effect of the lens, the small amplitude motion artifact is inhibited and the signal-to-noise is improved. The cardiac rate is obtained based on the PhotoPlethysmoGraphy (PPG). We use the LED as the light source and use the photoelectric diode as the receiving tube. The LED and the photoelectric diode are on the different sides of the beam splitter prism and they form the optical system. The signal processing and display unit is composed by the signal processing circuit, data acquisition device and computer. The light emitted by the modulated LED is collimated by the lens and irradiate the measurement target through the beam splitter prism. The light reflected by the target is focused on the receiving tube through the beam splitter prism and another lens. The signal received by the photoelectric diode is processed by the analog circuit and obtained by the data acquisition device. Through the filtering and Fast Fourier Transform, the cardiac rate is achieved. We get the real time cardiac rate by the moving average method. We experiment with 30 volunteers, containing different genders and different ages. We compare the signals captured by this method to a conventional PPG signal captured concurrently from a finger. The results of the experiments are all relatively agreeable and the difference is about 2bmp.

8855-5, Session 2

Digital holographic tomography using a light back propagation method and its application for refractive index measurement

Takanori Nomura, Takahiro Kitazawa, Wakayama Univ. (Japan)

Digital holography is one of the two-dimensional measurement methods for refractive index distribution. Refractive index distribution is obtained from phase distribution measured by digital holography.

In digital holographic tomography, which combines digital holography and filtered back projection method, it enables to measure three-dimensional distribution of refractive index. However, a filtered back projection method requires a little phase delay of a measured specimen. The amount of phase delay should be so small that the effect of the refraction is negligible. Therefore, digital holographic tomography using filtered back projection method is used as an imaging digital holography. It can only measure small objects such as pollen cells with a diameter of 30 micrometer. In this paper, a lensless digital holographic tomography using not a filtered back propagation method but a light back propagation method is proposed. In the proposed method, the light propagates along a refracted optical path because the phase distribution of the detector. Therefore the deflection from a true optical path is reduced. For the measurement of specimen with a huge refraction angle, our proposed method improves on measurement accuracy compared with a conventional filtered back projection method. Both numerical simulations and optical experiments are given to confirm the feasibility of the proposed method.

8855-6, Session 2

Designing the acousto-optical cell for optical spectrometer incorporated into the Guillermo Haro astrophysical observatory

Alexandre S. Shcherbakov, Adan O. Arellanes, Vahram Chavushyan, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

Optical spectrometer of the Guillermo Haro astrophysical observatory (Mexico) exploits mechanically removable diffraction gratings as dispersive elements. This spectrometer uses the gratings having 50 – 600 lines/mm with the optical apertures 9 x 9 cm that provide the first order spectral resolution from 9.6 to 0.8 A/pixel, respectively, in the range 400 – 1000 nm. However, the needed mechanical manipulations, namely, replacing the diffraction gratings with various resolutions and following recalibration of spectrometer within studying even the same object are inconvenient and lead to loosing rather expensive time for observation. We suggest exploiting an acousto-optical cell as a dispersive element in that spectrometer. Potentially, involving acousto-optical technique, which can realize tuning both the spectral resolution and the range of observation electronically, makes possible eliminating the above-mentioned demerits. The requirements to the cell combine a large optical aperture with the needed stroke-density and possibly high efficiency of operation under an acceptable acoustic power. This is why initially we consider the stroke-density 300 lines/mm. The analysis shows that at least the following materials can be used for designing similar cell. It can be lithium niobate ($LiNbO_3$)-crystal excited by the longitudinal acoustic mode along the [100]-axis at the frequency 2 GHz. This selection gives 300 lines/mm with total losses ~5.4 dB/aperture. Then, one can consider bismuth germanate ($Bi_{12}GeO_{20}$)-crystal using the shear acoustic mode along the [110]-axis at 0.53 GHz, so that the density 300 lines/mm appears with the losses ~6.3 dB/aperture. The neighboring figures of acousto-optical merit for these materials promise desirable efficiencies of operation, acceptable for astrophysical observations.

8855-7, Session 2

Fast hologram pattern generation by wave field translation

Seok Lee, Samsung Advanced Institute of Technology (Korea, Republic of); Ho-Cheon Wey, SAMSUNG Electronics Co., Ltd. (Korea, Republic of); Dongkyung Nam, Dusik Park, Samsung Advanced Institute of Technology (Korea, Republic of)

Holographic display is considered as ideal 3D display because it can generate whole 3D information of light distribution which can be seen in any direction without visual discomfort. Computer generated hologram (CGH) can be made from discrete input signal such as color plus depth data. In previous work of authors, radial symmetric interpolation (RSI) method which exploits concentric redundancy of point hologram was proposed. In this approach, pattern generation complexity is reduced by substituting calculation of wave equation by copy operation using elemental fringe LUT. However, the performance of point source based method is limited by accumulation complexity. Every point hologram for each object point should be accumulated to obtain final hologram pattern, and as input point number increases, this accumulation complexity becomes dominant compared to pattern calculation complexity. In this paper, we present a 2 step hologram pattern generation method to overcome this accumulation problem of point source based method. Proposed method consists of two steps. In the first step, 2D projection of wave field for 3D object is calculated by RSI method to the predefined reference depth. Then in the second step, 2D wave field which is obtained from first step is translated toward depth direction and hologram pattern in SLM plane is calculated by FFT based algorithm on the Fresnel or Fraunhofer approximation. The effectiveness of method is proved by computer simulation and optical experiment. Experimental results show that proposed method is 3878 times faster than analytic method, and 226.4 times faster than RSI method.

8855-8, Session 2

Improvement of off-axis holographic storage with multi-layer recording medium

Chih-Yuan Cheng, Yeh-Wei Yu, Ching-Cherng Sun, National Central Univ. (Taiwan)

There are many applications of holography, such as three-dimensional image, holographic optical testing, holographic optical element, holographic data storage, etc. The holographic data storage is superior to traditional optical data storage for high transfer rate and high capacity. In general, the recording medium of holographic data storage is single layer. In order to get larger storage capacity, the medium is supposed to be thicker. However, it makes the storage system sensitive to thermal expansion. In this paper, we propose a multi-layer recording medium in the off-axis holographic data storage that improves the thermal tolerance and maintains the shifting selectivity simultaneously. We derive the diffraction formula with thermal expansion based on the VOHIL theory, and then simulate the performance of the single layer recording medium of the system, including shifting selectivity and thermal tolerance. Finally we analyze the shifting selectivity and the thermal tolerance with different arrangement of the multi-layer recording medium.

8855-9, Session 2

Storage density estimation for the phase-encoding and shift multiplexing holographic optical correlator

Tianxiang Zheng, Liangcai Cao, Qingsheng He, Guofan Jin, Tsinghua Univ. (China)

Optical holographic data storage has been a vibrant area of research

[1]. The object and reference beams interfere inside volume holographic memories, e. g. a LiNbO3 crystal, and the stationary interference patterns are formed inside the recording medium by the refractive index modulation [2]. Thousands of the data pages can be stored inside one single location in the crystal through angular, phase-encoded, wavelength, or by more than one of these techniques in combination [3]. The high performance volume holographic correlator is based on the high-density holographic storage and has potential applications in associative retrieval, pattern recognition, target tracking, among others [4].

As the volume information density (VID) is crucial for a storage system, the VID needs to be estimated precisely. The VID follows VID=DA/V, where DA is the amount of data stored and V is the corresponding storage volume where the holograms are recorded. However, V is always estimated by the meeting volume formed by the object beam and reference beam in the traditional method. When multiple locations of a same crystal are applied for data storage, the estimation of V with the method mentioned is not precise. The value of V could be more credible if determined by the experiment. In this manuscript, we propose a system with a precise 2D translation stage for positioning the crystal. With this system, the minimum storing volume for one location is estimated precisely by translating the crystal until the stored data in one location of the crystal cannot be detected. So the optical holographic storage density is estimated with a high accuracy.

A hybrid shift multiplexing method for an off-axis optical holographic storage is proposed. When storing pages of data into different locations in the crystal, multiple phase masks are applied into the object beams. Each phase mask corresponds to one location. Compared with the non-phase-mask method, the minimum storing volume for one storage location is reduced, due to the selectivity introduced by different masks. The VID is enhanced with the phase mask method. The optical storage density of the storage system, with phase mask, is estimated with a translation stage in the experiments. The estimated density is more accurate than with the traditional method and the density rises with the phase-encoded multiplexing method. It enables the optical storage system for the applications as high speed computation.

Integration of coherent optical OFDM with WDM

Khaled S. Alatawi, Fahad M. Almasoudi, Mohammad Matin, Univ. of Denver (United States)

Orthogonal Frequency Division Multiplexing (OFDM) got a great attention in optical communications due to its ability to overcome different limitations in optical fiber such as polarization mode dispersion and chromatic dispersion. Coherent optical OFDM (CO-OFDM) combines the attractive advantages of both OFDM and coherent detection. CO-OFDM has proved to be an efficient technique that can be used in high speed optical transmission and to enhance the data to exceed 100 Gbits/s due to its high spectral efficiency and ability to overcome fiber dispersion. WDM (Wavelength division multiplexing) is an optical technique used to extend the bandwidth and support high data rate where many signals can be combined and transmitted at the same time. This paper proposes a system design that integrates CO-OFDM with WDM to reach data rate of 400 Gbits/s over 1000 Km Single Mode Fiber (SMF). The 400 Gbits/s signal is generated by multiplexing eight OFDM with 50 Gbits/s for each OFDM. Two different scenarios are studied and compared to analyze the performance of the system to find out how the dispersion and the nonlinearities affect the system. The first scenario is to study the performance of CO- OFDM WDM back to back design by measuring the BER and the OSNR (Optical Signal to Noise Ratio) of different WDM channels and studying the constellation diagram of each user. The second scenario is to study the performance of CO-OFDM WDM for 1000 Km SMF by measuring the BER and the OSNR of different WDM channels and studying the constellation diagram of each user.

Theoretical and experimental examination of PQ-PMMA photopolymer material

Yue Qi, Haoyu Li, Univ. College Dublin (Ireland); Elen Tolstik, Friedrich-Schiller-Univ. Jena (Germany); Jinxin Guo, Univ. College Dublin (Ireland); Emily M. Gleeson, National Univ. of Ireland, Maynooth (Ireland); V. Matuevich, Richard M. Kowarschik, Friedrich-Schiller-Univ. Jena (Germany); John T. Sheridan, Univ. College Dublin (Ireland)

Phenanthrenequinone (PQ) doped poly(methyl methacrylate) (PMMA) photopolymer material has been studied extensively due to the growing interest in application involving photopolymers. However, to progress the development a more physical material model has become necessary. In this article, a kinetic model is developed, which includes: (i) the time varying photon absorption, including the absorptivity of a second absorber, i.e., the singlet excited state of PQ, (ii) the recovery/regeneration and the bleaching of the excited state PQ, (iii) the nonlocal effect, and (iv) the diffusion effects of both the ground and excited state PQ molecules and of the methyl methacrylate (MMA). A set of rate equations are derived, governing the temporal and spatial variations of each chemical component concentration. The validity of the proposed model is examined by applying it to fit experimental data for PQ-PMMA layers containing three different initial PQ concentrations, i.e., 1 mol.%, 2 mol.% and 3 mol.%. The effect of different exposure intensities is also examined. Material parameters are extracted by numerically fitting experimentally measure normalized transmission curves and the refractive index modulation growth curve using the theoretical models.

Spatial frequency response of AA/PVA photopolymer material containing four different photosensitizers

Yue Qi, Haoyu Li, Jinxin Guo, Univ. College Dublin (Ireland); Michael R. Gleeson, National Univ. of Ireland, Maynooth (Ireland); John T. Sheridan, Univ. College Dublin (Ireland)

Based on the previous study of the time varying photon absorption effects, the behaviour of four different photosensitizers in an AA/PVA photopolymer material has been further examined by using the developed 1-D Nonlocal Photo-polymerization Driven Diffusion (NPDD) model. In order to characterise the photosensitizers precisely, holographic illuminations with different spatial frequencies are applied. Material parameters, i.e., the nonlocal response parameter, ?, the diffusion rate of monomer, Dm, the chain initiation kinetic constant, ki, and the termination rate, kt, are extracted by numerically fitting experimentally measure the refractive index modulation growth curve using the theoretical models. In this paper, the four different photosensitizers under investigation are Erythrosin B; Eosin Y; Phloxine B; Rose Bengal.

8855-30, Session PWed

Anaglyph stereo images generated from objects topography obtained by projection fringes

Amalia Martínez-García, Yolanda Y. Lopez Dominguez, Juan-Antonio Rayas-Alvarez, Ctr. de Investigaciones en Óptica, A.C. (Mexico); Katia Genovese, Univ. degli Studi della Basilicata (Italy)

The structured light techniques are useful to evaluate the topography of an object. A grid of straight lines is projected onto the surface of a diffusely reflective object. By using the Fourier transform the phase of a fringe pattern is obtained from a single image. With the phase information and the sensibility vector of the optical system the value at each object´s point is determined. On the other hand, 3D visualization is possible by using a stereoscopic system that provides two different images of the same object (one for each eye). One possible technique is that known as the anaglyph method. This is based on the binocular disparity of two images obtained with different color filters. Each one of the images is taken with complementary colors (red-blue or red-green). The tri-dimensional shape is observed by the use of special glasses. In this form, every eye sees an image from its own angle. The object topography is obtained with the fringe projection technique and then one image is selected and pseudo colored. Then, the second image is taken by slightly changing the perspective of the tri-dimensional display and pseudo coloring it with a complimentary color. A computational algorithm is developed to evaluate and visualize the object in real time which uses the spectral absorption curves of the glasses, the spectral density functions of the display primaries and the colorimetric properties of the human observer. Experimental results are shown of the evaluation and visualization of a porcine vascular segment.

Enhancement of nonlinear phase shift for format conversion in silicon waveguides

Ping Zhou, Shiming Gao, Zhejiang Univ. (China); XiBin Li, Centre for Optical and Electromagnetic Research (China) and Zhejiang Univ (China); Kai Hu, Centre for Optical and Electromagnetic Research (China)

Different modulation formats may be required in different optical communications networks. Differential phase-shifted keying (DPSK) format is competitive for long-haul transmission and on-off keying (OOK) format is suitable for metropolitan area networks. As a result, format conversion is needed from intensity format to phase format in edge nodes. Silicon waveguides based on silicon-on-insulator technique have attracted increasing attentions for nonlinear applications due to its strong third-order nonlinearity and large refractive index contrast. Cross-phase modulation (XPM) in silicon waveguides provides a promising way to realize all-optical integrated format conversion since a nonlinear phase shift is induced to the probe by the incident signal power. An OOK format can be converted to DPSK format if nonlinear phase shift of π is generated. In this paper, the nonlinear phase shift caused by XPM have been numerically investigated. The influences of the walk-off effect, group-velocity dispersion, and nonlinear losses (including two- photon absorption (TPA) and free-carrier absorption (FCA)) on the nonlinear phase shift have been analyzed in detail. We tried to enhance the nonlinear phase shift by cancelling these influences. We found that the walk-off effect can be minimized by carefully choosing the zero dispersion wavelength of the used silicon waveguide and the probe wavelength to make the signal and the probe symmetrically. Flat and small dispersion is beneficial to acquire a large nonlinear phase shift. TPA and FCA will greatly reduce the nonlinear phase shift obtained from XPM and they should be effectively suppressed in order to realize high-quality format conversion.

Known plain-text attack on asymmetric cryptosystem

Sudheesh K. Rajput, Naveen K. Nishchal, Indian Institute of Technology Patna (India)

It is believed that asymmetric cryptosystem based on phase-truncated Fourier transform has immunity against known-plaintext attack. However, generation of two asymmetric keys is possible, if plaintext-ciphertext pair is known. In this paper, we show that amplitude- and phase- truncation-based asymmetric cryptosystem is vulnerable to known-plaintext attack. The decryption keys are generated with the help of modified Gerchberg-Saxton phase retrieval algorithm from known-plaintext and cipher-text. The first key is generated from known-plaintext and the second key is generated from the cipher-text. With the help of the generated keys, the encrypted image in one domain is decrypted successfully in another domain. The domains used for this study are Fourier, Fresnel, or fractional Fourier domain. The vulnerability is proved through the results of computer simulation.

Analysis of the fabrication of diffractive optical elements in photopolymers

Sergi Gallego, Andrés Márquez, Roberto Fernández, Álvaro Piera, Francisco J. Martínez-Guardiola, Jorge Francés Monllor, Augusto Beléndez, Inmaculada Pascual, Manuel Ortuño, Univ. de Alicante (Spain)

Recently the possibility to record phase diffractive optical elements (DOEs) onto photopolymers has been explored. The use of a spatial light modulator gives us the possibility to record a wide range of diffractive elements. Sharp profiles may as well present a smoothing of the edges due to various reasons: a low pass filtering of the optical system, material properties, etc. In this work we have analyzed the importance of some of these aspects of the photopolymer and the experimental set-up in order to record high quality DOEs. The photopolymer analyzed is based on polyvinylalcohol/acrylamide.

Spatial attributes of the diffraction field

Javier Muñoz-Lopez, Gabriel Martinez-Niconoff, Gerardo Diaz-Gonzalez, Javier Silva-Barranco, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Patricia Martínez Vara, Benemérita Univ. Autónoma de Puebla (Mexico)

Optical diffraction fields have in general a spatial complex structure and some times can generate focusing regions, in this work we describe the focusing region associated with highly symmetric transmittances, analyzing its associated phase function. We show that generic features can be studied from a differential equation for a focusing geometry, which is obtained through angular representation for diffraction fields, according to the choice of the parameters involved, the diffraction field presents a new focusing region whose geometry and spatial evolution can be described with the only analysis of the phase singularities avoiding the integral representation.

An object boundary detection system based on a 3D stereo monitor

Shuqun Zhang, College of Staten Island (United States)

Finding object boundary is one of the most challenging tasks in image processing, and it has important applications in many areas such as medical and biological imaging. Numerous image segmentation algorithms have been proposed to detect object boundary, among which active contours, level set methods and graph cut are widely used especially for medical images because of their good performance in segmentation. These algorithms are usually computational expensive due to many iterations needed and thus not suitable for real-time processing. Optical processing can be used for real-time object detection through utilizing parallel processing and implementing high-pass filters, but it is impractical due to coherent illumination needed and unsatisfied results. In this paper we propose a novel object boundary detection system based on a 3D stereo monitor. The image processing is based on controlling the polarization of LCD and the way the image is display on a 3D monitor to enhance object boundary. The users can see the enhanced contour of the object through a 3D polarization glasses in real-time, which can be also recorded using a camera for further processing. A software is developed for user interaction to achieve better results. The effectiveness of the system is demonstrated using various medical and biological images. It has the advantages of high speed processing and robustness to noise over the digital methods.

8855-10, Session 3

Implementation of a photonic antenna in optical OFDM link

Salih Kenshil, Gasem Rashwan, Univ. of Denver (United States)

The integration of photonic antennas with radio over fiber (RoF) systems can serve high dense populated areas such as airports, shopping centers, dead-zone area and tunnels. In this paper, we present an optical wireless communication downlink with a photonic antenna. Our proposed radio over fiber (RoF) system is to carry modulated orthogonal frequency division multiplexing (OFDM) signals with a 2.4 GHz radio frequency over a cost effective optical link. A comparison of using the photonic antenna as a passive and an active in the RoF system is presented. The active photonic antenna (APHA) is mounted at the end of the optical link to the photodiode as a package of a band-pass filter (BPF) and a radio frequency power amplifier. The photonic antenna scattering parameters are implemented into the optical system simulation tools at various fiber length and free space loss (FSL). The wireless link is implemented for a transmission distance up to 100 meters. The transmitted signal is fully carried over a radio frequency signal and then optically carried over a standard single mode fiber (SSMF). The measurements of the EIPR and SNR were done with 0 dBm RF input into the directly modulated laser (DML) for all the simulations. The results show that the analog optical wireless link is very suitable to carry the OFDM signals. Moreover, the active photonic antenna provides sufficient service for more than 30 meters compared to passive antenna.

Optical signal impairment study of cascaded optical filters in 40 Gbps DQPSK and 100 Gbps PM-DQPSK systems

Xiaoyong Chen, Paloma R. Rodriguez-Horche, Alfredo Martín-Mínguez, Univ. Politécnica de Madrid (Spain)

The optical filter is a crucial element in optical communications. The influence of cascaded filters in the optical signal will affect the communications quality seriously. In this paper we will study and simulate the optical signal impairment caused by different kinds of filters which include Butterworth, Bessel, Fiber Bragg Grating (FBG) and Fabry-Perot (F-P). Optical signal impairment is analyzed from an Eye Opening Penalty (EOP) and optical spectrum point of view. The simulation results show that when the center frequency of all filters aligns with the laser's frequency, the Butterworth has the smallest influence to the signal while the F-P has the biggest. With an 1-dB EOP, the amount of cascaded Butterworth optical filters with a bandwidth of 50 GHz is 18 in 40 Gbps NRZ-DQPSK systems and 12 in 100 Gbps PM-NRZ-DQPSK systems. The value is reduced to 9 and 6 respectively for Febry-Perot optical filters. In the situation of frequency misalignment, the impairment caused by filters is more serious. Our research shows that with a frequency deviation of 5 GHz, only 12 and 9 Butterworth optical filters can be cascaded in 40 Gbps NRZ-DQPSK systems and 100 Gbps PM-NRZ-DQPSK systems respectively. We also study the signal impairment caused by different orders of the Butterworth filter model. Our study shows that although the higher-order has a smaller clipping effect in the transmission spectrum, it will introduce a more serious phase ripple which seriously affects the signal. Simulation result shows that the 2nd order Butterworth filter has the best performance.

8855-12, Session 3

PAPR mitigation algorithms for OFDM WiMAX link

Gasem Rashwan, Salih Kenshil, Univ. of Denver (United States)

OFDM has been adopted in many high systems due to its high data rates and to its robust performance in fading channel. OFDM distributes the data among number of carriers which are called subcarriers. The subcarriers must be orthogonal to prevent the carrier from interfering to each other. Features such overcoming ISI (inter-symbol interference) and the complexity of Designing both receiver and transmitter made it ideal technique for both wired and wireless communication as long as optical communications. However, OFDM suffers from a defect called Peak Average power ratio (PAPR). APARP is crucial drawback that limits the way that OFDM functions and reducing or mitigating this factor in wireless and optical environment will help overcome and enhance the OFDM date rate. PAPR is the main cause of inter-carrier interference and high out-of-band power, and consequently Bit error rate BER. We investigate some of the techniques that mitigate the effect of PAPR. These techniques are merged together to provide a better PAPR reduction with the existing techniques. In this paper, we are proposing a new reduction algorithm to minimize the effect of the PAPR. The results and simulation are done in Optisystem V-11 and Matlab environment. These approaches will be applied on WiMAX application and the performances between the different techniques are examined.

Electro-optic logic circuits based on silicon microring switches

Lin Yang, Lei Zhang, Yonghui Tian, Institute of Semiconductors (China)

Electro-optic logic is a paradigm which employs the optical switch network to perform the logical operation. The status of each switch in the optical network is determined by an electrical Boolean signal applied to it. The operation of each switch is independent of the operations of other switches in the network and the operation result propagates in the network at the speed of light. The overall latency of the logic circuit is very small and all switches perform their operations almost simultaneously. Therefore, the electro-optic logic has a very high operation speed [1-4]. Silicon microring resonator is an attractive structure owing to its outstanding performances, such as compact size, ultra-low power consumption and CMOS-compatible process. Therefore, the electro-optic logic based on silicon microring switches is easy to realize large-scale integration and low-cost manufacture in a high-volume CMOS-photonics foundry. In the past several years, we proposed and demonstrated a series of electro-optic logic circuits based on silicon microring switches including NOT, XOR/XNOR, OR/NOR, AND/NAND, encoder, decoder and half-adder [5-13]. In this paper, we will review our recent research on electro-optic logic circuits based on silicon microring switches and introduce our new development in this topic.

8855-14, Session 4

On-chip optical matrix-vector multiplier *(Invited Paper)*

Lin Yang, Lei Zhang, Ruiqiang Ji, Institute of Semiconductors (China)

Matrix-vector multiplication is a fundamental operation in modern digital signal processing fields. Inspired by the intrinsic spatial parallelism of optics, much effort has been made to develop optical apparatuses that can perform such a parallelizable operation. The Stanford multiplier [1] is one of the most notable demonstrations, which is composed of light source array, optical lens, spatial light modulator (SLM) matrix and photodetector array. Almost all implementations are large in volume and high in power consumption. Moreover, many removable elements adopted make them extremely sensitive to the environmental vibration. To overcome these limitations, we propose an on-chip optical matrix-vector multiplier (MVM), which is composed of laser-modulator array, multiplexer, splitter, microring modulator matrix and photodetector array. Compared with traditional implementations, the use of wavelength multiplexing simplifies the fan-out and fan-in sub-systems. And the use of high-speed, planar integrated, wavelength specific 2-D matrix simplifies the low-speed, bulk, monochromatic 3-D spatial light modulators. The fan-out and fan-in with optical lenses in the traditional optical MVMs are replaced by the power splitting and wavelength multiplexing with waveguide devices in the proposed optical MVM, which greatly reduces the complexity and size of the system. The discrete components in the traditional optical MVMs are replaced by the integrated ones in the proposed optical MVM, which improves the stability and power efficiency of the system. 8x107 multiplications and accumulations per second is implemented by a demo system with a 4x4 microring modulator matrix [2]. Theoretical maximum performance of the proposed architecture is analyzed based on current technological level.

Highway traffic segmentation and classification using super-resolution and Gaussian mixture model

Amr H. Yousef, Jeff Flora, Khan M. Iftekharuddin, Old Dominion Univ. (United States)

Super-resolution (SR) refers to reconstructing a single high resolution (HR) image from a set of subsampled, blurred and noisy low resolution (LR) images. In many cases, the acquisition sensors such as the video cameras that monitor the highway traffic have very limited quality. The reconstructed image suffers from degradations such as blur, aliasing and photo-detector noise which results in poor performance of the segmentation and classification of high way traffic. Our goal is to identify and extract individual vehicles from a highway traffic scene in these low quality images under different weather conditions. In this paper, we introduce a new fast stochastic Wiener filter to enhance spatial details and reduce acquisition artifacts through SR reconstruction. Wiener filter can be used to remove artifacts and enhance the visual quality of the reconstructed images. Our derivation depends on the continuous-discrete-continuous (CDC) model that represents most of the degradations encountered during the image-gathering and image-display processes. In addition, we incorporate a new parameter that accounts for LR images registration and fusion errors. Also, we speeded up the performance of the filter by constraining it to work on small patches of the images. We subsequently utilize (GMM) method to extract individual vehicles in a frame. Individual vehicles are clustered and detected from the segmented scene through the use of a series of morphological operations, followed by two-dimensional connected component labeling. We evaluate our hybrid approach quantitatively and qualitatively in segmentation and classification of the extracted vehicles.

Object tracking under nonuniform illumination with adaptive correlation filtering

Kenia Picos, Victor H. Díaz-Ramírez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada (Mexico)

A real-time system for illumination-invariant object tracking is proposed. The system is able to estimate at high-rate the position of a moving target in an input scene, that is affected by presence of a high cluttering background and nonuniform illumination conditions. The position of the target is estimated with the help of a filter bank implemented on a graphics processing unit, exploiting massive parallelism. The filters in the bank, adapt their parameters according to the local statistics of the observed scene, in a small region centered at coordinates of a predicted position for the target. As a result, we can reduce the size of the input frame to search for the target, and we can reduce the number of required filters in the bank to increase operation speed. The predicted position for the target is carried out by exploiting information of present and past frames, and by using the coordinated turn motion model of the target in a two-dimensional plane. Computer simulation results obtained with the proposed system are presented and discussed in terms of tracking accuracy, computational complexity, and tolerance to nonuniform illumination.

A novel discretization method with geometric symmetry for image reconstruction

Jun Qiu, Beijing Information Science & Technology Univ. (China); Ming Jiang, Peking Univ. (China); Chang Liu, Beijing Information Science & Technology Univ. (China)

Pixel based discretization is currently applied in image reconstruction for computerized tomography(CT), but it does not take into account the geometry symmetry of scanning configuration. In this work, we propose a discretization method for the image reconstruction of CT. Based on the scanning configuration and image resolution under reconstruction, the Radon transform is discretized to minimize the sampling artifacts. In this discretization, the projection coefficient is weighted by the distance from the pixel to the ray rather than the intersection. So the sampling error by convolution is reduced. Further more, this discretization can lead to faster algorithms implementation because of its symmetric structure. The projection coefficient is the transformation invariance in this discretization, as well as the pixel position and the line position. We propose a block iterative image reconstruction algorithm by incorporating the geometry symmetry of the proposed discretization and projection onto convex sets (POCS) method. Experiments demonstrate the performance of the proposed discretization method and reconstruction algorithm in terms of image resolution and contrast and computing expense. This discretization method can also be applied to other image modalities.

One orthogonal multi-mask spectral image inversion algorithm for computational imaging spectrometry

Yangyang Liu, Bin Xiangli, Qunbo Lv, Mingxiang Huang, Jinsong Zhou, The Academy of Opto-Electronics (China)

Computational imaging spectrometry (CIS) technology dispersed by one prism has been discussed in recent years. It has the advantage of high optical throughput , high resolution of spatial-spectral data-cube by rapid data inversion. However, CIS also has some disadvantages like aliasing in spatial-spectral image and insufficiency of sparse sampling which may reduce the accuracy of reconstructed spatial-spectral data-cube. Therefore, the spectral image inversion is one seriously crucial step for accomplishing its theoretical advantages.

In this paper, focusing on spectral image inversion, the algorithms, including image reconstruction, image compressed sensing and spectral image inversion theories were illustrated briefly . By pointing out the key issue of spectral image inversion ,one improved spectral image inversion algorithm with coded aperture function of orthogonal multi-frame is put forward, named as orthogonal multi-mask spectral image inversion algorithm (shortly for OMSII). OMSII algorithm relies on multi-frame exposures of CIS by the special mask. The newly designed coded aperture function has same characteristics with multi orthogonal and its self-recycle, some similar to the hadamard transform S recycle matrix.

According to computer simulation, compared to traditional spectral image inversion algorithms based on image compressed sensing theories , OMSII algorithm reconstructs spatial-spectral data-cube of higher quality, also the number of spectral band exceeds to ordinary hadamard transform spectral image inversion .Moreover, the spatial-spectral image aliasing is reduced. Based on the principle analysis with simulation results by virtue of OMSII algorithm, the key spatial-spectral sparsity of sampling data is well satisfied which improves the reconstruct accuracy a lot. So it has proved and provided one optimized route for CIS inversion algorithm, has with bigger feasibility for realizing the CIS theoretical advantages and ensuring CIS be more suitable technology for applications.

A recognition method in holographic data storage system by using structural similarity

Yu-Ta Chen, National Central Univ. (Taiwan); Ou-Yang Mang, National Chiao Tung Univ. (Taiwan); Cheng-Chung Lee, National Central Univ. (Taiwan)

With the huge quantities of information increasing, the data storage requires more capacity to fill with the information. Then, the next generation of data storage, holographic data storage system (HDSS) can perform the task. The striking difference between HDSS and the conventional data storage (compact disc) is the record of page-oriented image. The page-oriented image would be influenced by the adverse effects such as thermal noise, misalignment and aberration in the HDSS. For reducing the effects, several methods such as image processing and error correction code have been developed in HDSS. In this article, we proposed a concept of the recognizable method in the image prepossessing of the HDSS by using structural similarity (SSIM) method. As a distorted image is received by the image sensor, the recognizable method utilizes a database of the reference image to compare with part of the distorted image and the degree of similarity between the images of the reference and distorted is determined by the SSIM method. Then, the reference image with maximum degree of similarity is regarded as binary data carried by the part of the distorted image.

Robustness of double random phase encoding spread-space spread-spectrum image watermarking technique

Shi Liu, Univ. College Dublin (Ireland); Bryan M. Hennelly, National Univ. of Ireland, Maynooth (Ireland); John T. Sheridan, Univ. College Dublin (Ireland)

In this paper the robustness of a recently proposed image watermarking scheme is investigated, namely the Double Random Phase Encoding spread-space spread-spectrum watermarking (DRPE SS-SS) technique. In the DRPE SS-SS method, the watermark is in the form of a digital barcode image which is numerically encrypted using a simulation of the optical DRPE process. This produces a random complex image, which is then processed to form a real valued random image with a low number of quantization levels. This signal is added to the host image. Extraction of the barcode, involves applying an inverse DRPE process to the watermarked image followed by a low pass filter. This algorithm is designed to utilize the capability of the DRPE to reversibly spread the energy of the watermarking information in both the space and spatial frequency domains, and the energy of the watermark in any spatial or spatial frequency bin is very small. The common geometric transformations and signal processing operations are performed using both the informed and the blind detections for different barcode widths and different quantization levels. The results presented indicate that the DRPE SS-SS method is robust to scaling, JPEG compression distortion, cropping, low pass and high pass filtering. It is also demonstrated that the bigger the barcode width is, the lower the false positive rate will be.

8855-21, Session 5

Monte Carlo simulation of neutron and other noise effects on beam position determination with real and simulated beam images at the National Ignition Facility

Abdul A. S. Awwal, Richard R. Leach, Philip S. Datte, Lawrence Livermore National Lab. (United States)

Images obtained through charged coupled device (CCD) cameras in the National Ignition Facility (NIF) are crucial to precise alignment of the 192 laser beams to the NIF target-chamber center (TCC). Cameras in and around the target chamber are increasingly exposed to the effects of neutron radiation as the laser power is increased for high energy fusion experiments. NIF was carefully designed to operate under these conditions. The present work examines the degradation of the measured TCC camera position accuracy resulting from the effects of neutron radiation on the sensor and verifies operation within design specifications. Both synthetic and real beam images are used for measuring position degradation. Monte Carlo simulations based on camera performance models are used to create images with added neutron noise. These models predict neutron induced camera noise based on exposure estimates of the cumulative single-shot fluence in the NIF environment. The neutron induced noise images are used to measure beam positions on a target calculated from the alignment images with the added noise. The effects of this noise are also determined using noise artifacts from real camera images viewing TCC to estimate beam position uncertainty.

*This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

Data mining with unsupervised clustering using photonic micro-ring resonators

Alastair D. McAulay, Lehigh Univ. (United States)

Data is commonly located in an optical format or moved through optical fiber in modern data centers. Therefore we review optical supervised and unsupervised systems for performing data mining operations. Chapter 14 in “Optical Computer Architectures” by A.D. McAulay (1992) describes an ultrafast optical dataflow correlator designed and constructed for the military to search for a known word or pattern in a supervised manner. More recently data mining makes extensive use of unsupervised learning (T. Kohonnen, book 1984) to find clusters in a database. The clusters provide significant information on relations between parameters in the database for the purpose of targeting advertising and planning. Micro-ring resonators have the potential to allow photonic circuits that match that of VLSI electronic circuits (SPIE 5595-48, McAulay et al). Therefore we propose that parameters corresponding to points in a database are converted from analog values to frequencies, as in done in the brain’s neurons (SPIE 6775-10, McAulay). We showed in SPIE 5809-49, (McAulay and Tong) that when micro ring resonators of close frequencies are placed near each other, the frequencies will move into step with each other through weak coupling. Therefore, in time, a group of resonators will form clusters of similar frequencies that will indicate the desired parameters having close relations.

8855-23, Session 5

The laser range profile and range imaging of a coarse cone

Yanhui Li, Zhensen Wu, Lu Bai, Haiying Li, Yunhua Cao, Xidian Univ. (China)

Profile information about a three-dimensional target can be obtained directly by analyzing two-dimensional data of the laser range profile and the laser range imaging. A backscattering model of average signal power function for laser radar range imagery obtained by a short pulse laser for a coarse cone is presented in this paper. This model can analyze the laser range profile and range imaging which relate the average power seen by the receiver with laser pulse, target shape, optical scattering properties of surface material, incidence angle and other factors. The optical scattering property of the material is characterized by bidirectional reflectivity distribution function (BRDF). Based on BRDF, the optical scattering is considered. Simulation of the laser range profile and range imaging of a coarse cone is given, and the effects of some parameters including half-cone angle, surface optical scattering property, laser pulse width and incidence angle on the received power can be analyzed. Based on the results of the simulated model and theoretical analysis, the cone can be identified. The model can be used for demonstration of 3D laser radar system and can also be used to generate library of model data sets for automatic target recognition.

8855-24, Session 5

Filling gaps in Landsat ETM+ SLC-off images based on Bayesian estimation and non-local means

Peng Liu, Institute of Remote Sensing and Digital Earth (China)

Since its first launch in 1972, Landsat satellite series have been continuously collecting images of the earth from space. However, the scan-line corrector (SLC) of Landsat-7 Enhanced Thematic Mapper Plus (ETM+) sensor failed permanently on May 31st, 2003. It caused roughly 20% of the pixels to be un-scanned in any ETM+ images. In this paper, Landsat-5 TM images from similar dates and similar scenes are used as reference image to fill gaps of Landsat-7 SLC-off ETM+ images. We use the Bayesian theory to model the relationship between reference images of Landsat-5 and the target images of Landsat-7. Based on the maximum a posteriori criterion (MAP), we get an equation with respect to the pixels scanned in target image, pixel un-scanned in target images and the correspond pixels in the reference image. Based on the conditional posteriori probability, the un-scanned pixels in the target image are referred by the statistical characters of pixels from both neighborhood of target images and reference images. And the non-local means method is introduced into the MAP estimation. Based on non-local means, the most similar pixels to the target pixels are selected and weighted, and as the samples for the estimation of the un-scanned pixels in the target image. The redundant of texture in images and the spectral correlationship between Landsat5 images and Landsat-7 images make our MAP estimation very effective. We compared the proposed method with other state-of-the-art methods, and the better performances are shown in the experiments.

8855-25, Session 5

XOR/XNOR electro-optic logic circuit based on coupled-resonator-induced transparency

Yonghui Tian, Lei Zhang, Lin Yang, Institute of Semiconductors (China)

Electro-optic logic is a paradigm which employs the optical switch network to perform the logical operation. The status of each switch in the optical network is determined by an electrical Boolean signal applied to it. The operation of each switch is independent of the operations of other switches in the network and the operation result propagates in the network at the speed of light. The overall latency of the logic circuit is very small and all switches perform their operations almost simultaneously. Therefore, the electro-optic logic has a very high operation speed [1-4]. The presence of a coupled-resonator-induced transparency (CRIT) effect in parallelly coupled double microring resonators (MRRs) has been widely studied, and various applications based on the CRIT have been demonstrated [5-11]. As an application of the CRIT, we propose and demonstrate an electro-optic logic circuit which can implement XOR/XNOR operations using CRIT. The two electrical signals applied to the two MRRs carry the two operands of the logical operations, and the operation results are encoded on the output optical power. As proof-of-concept, a thermo-optic modulating scheme is employed with an operation speed of 10 kbps.

Research progress of depth detection in vision measurement: a novel project of bifocal imaging system for 3D measurement

Anhu Li, Ye Ding, Tongji Univ. (China); Yongcheng Liang, Shanghai Ocean Univ. (China); Yongjian Zhu, Zhejiang Univ. of Science and Technology (China); Zhizhong Li, Tongji Univ. (China)

Vision measurement technology has been widely used in the industrial measurement fields, which characterizes with the advantages of large range, high accuracy, high efficiency and non-contact measurement. The paper respectively reviews the recent research progresses of the monocular stereo vision measurement, the binocular stereo vision measurement and the multi-eye stereo vision measurement, and focuses on the existing approaches to obtain the depth information by the stereo vision. The advantages and disadvantages of the depth detection through the method of focus, defocus and zoom in monocular stereo vision are compared with each other. According to the above research background, a novel bifocal imaging measurement system based on the zoom method is proposed with the good performance of both the monocular and the binocular stereo vision. This imaging system consists of a primary lens and a secondary one with different focal length matching, in which two images can be acquired in the same exposure time. It can meet the large-range and high-resolution imaging requirements without time delay and imaging errors due to the multiple focus and zoom in the existing imaging system. At the same time, the system can meet the accuracy requirement under different measurement conditions through adjusting the different focal lengths of the secondary lens along the optical axis. This method is especially suitable for the online 3-D vision measurement, which can not only solve the real-time measurement problem of both static and dynamic targets, but also has an important significance for the industrial application.

8856-1, Session 1

Backward compatible JPEG lossy-to-lossless compression of medical data

Heng Chen, Geert Braeckman, Adrian Munteanu, Peter Schelkens, Vrije Univ. Brussel (Belgium) and iMinds (Belgium)

In this paper, we propose a novel reversible DCT-based lossy- to-lossless still image coding system for medical image data. We followed a two-layer design approach with traditional JPEG lossy compression being performed for the base layer, and lossless residual coding yields the enhancement layer. The enhancement layer bitstream is inserted into the base layer (JPEG) codestream and identified by a JPEG extension marker, in order to achieve backward compatibility.

From compression efficiency and functionality perspectives, JPEG 2000 is currently the best image codec available. JPEG-LS and JPEG XR yield competitive lossless compression performance, but none of them offers backward compatibility to the classical JPEG standard. Adding lossy-to-lossless functionality with our proposed system as an extension to the traditional JPEG standard, yields comparable lossless compression performance to that of JPEG-LS and JPEG XR while maintaining backward compatibility to the conventional JPEG. In this way, any imaging system, device, or application supporting JPEG can also decode the codestream produced by the new system without any modification.

8856-2, Session 1

Image enhancement for astronomical scenes

Jacob A. Lucas, Brandoch Calef, Boeing LTS Inc. (United States); Keith Knox, Air Force Research Lab. (United States)

Telescope images of astronomical objects and man-made satellites are frequently characterized by high dynamic range and low SNR. We consider the problem of how to enhance these images, with the aim of making them visually useful rather than radiometrically accurate. Standard contrast and histogram adjustment tends to strongly amplify noise in dark regions of the image. Sophisticated techniques have been developed to address this problem in the context of natural scenes. However, these techniques often misbehave when confronted with low-SNR scenes that are also mostly empty space. We compare two classes of algorithms: contrast-limited adaptive histogram equalization, which achieves spatial localization via a tiling of the image, and gradient-domain techniques, which perform localized contrast adjustment by non-linearly remapping the gradient of the image in a content-dependent manner. We extend these to include a priori knowledge of SNR and the processing (e.g. deconvolution) that was applied in the preparation of the image. The methods will be illustrated with images of satellites from a ground-based telescope.

8856-3, Session 1

Enhancement of image fusion methods

Yotam Ben-Shoshan, Yitzhak Yitzhaky, Ben-Gurion Univ. of the Negev (Israel)

Image fusion methods that can effectively combine information from different imaging sources have become more common due to the growing types and number of imaging sensors, and because it can be difficult for humans to effectively integrate visual information by viewing multiple displays separately. Hence, there is a need for combining streams with complementary information into one coherent representation in order to cope with the data overload. Fusion implementations are broadly common in medical, security, aviation, geoscience and other applications.

In this research we developed two novel techniques that can improve multi modal image fusion quality. The first technique is a decision algorithm that runs at the first stage of the fusion process. The algorithm determines the “polarity” of the images (i.e., assigning brighter or darker gray-level values to larger image intensities), under the assumption that fusion produces better results when the images are more similar. The second technique is a new approach for the composition stage in multi resolution fusion. Instead of fusing all pyramid levels using the combining method, we suggest to choose from the lowest levels in the pyramids only one image. The proposed techniques were implemented to various multi resolution fusion methods, including Lapalce pyramids, Ratio of Low Pass pyramids (ROLP) and Morphological pyramids. Pairs of thermal and either visual or near-IR images were employed in the fusion procedure. The experimental results indicate that the proposed methods lead to a better image fusion quality, with low computational cost, according to both objective and subjective fusion evaluations.

8856-4, Session 1

Adaptive design of composite correlation filters using multi-objective optimization

Alejandra Serrano Trujillo, Víctor H. Díaz Ramírez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Leonardo Trujillo Reyes, Instituto Tecnologico de Tijuana (Mexico)

In the design of composite correlation filters for pattern recognition, it is required to carefully choose a set of training templates for filter synthesis. The performance of these filters will highly depend on the proper selection of the training templates. Therefore, a strategy to choose the best training templates is desirable. In this work, we propose an adaptive algorithm for the design of composite correlation filters for pattern recognition. The algorithm, applies a genetic multi-objective optimization strategy to construct the optimal set of training templates for the synthesis of a composite filter with the best performance in terms of several conflicting metrics. To represent a potential solution within the feasible search space the proposed algorithm uses a variable length coding technique. Computer simulation results obtained by the proposed approach are presented and discussed in terms of several performance metrics, such as, discrimination capability, signal to noise ratio, and average similarity measure. These results are obtained by testing the performance of resulting composite filters in recognizing a geometrically distorted target in synthetic and real input scenes corrupted with overlapped and disjoint noise.

8856-5, Session 1

An improved approach to the cubic-spline interpolation

Tsung-Ching Lin, I-Shou Univ. (Taiwan); Shaohua Hong, Xiamen Univ. (China); Trieu-Kien Truong, I-Shou Univ. (Taiwan) and National Sun Yat-Sen Univ. (Taiwan); Lin Wang, Xiamen Univ. (China)

Cubic-spline interpolation (CSI) scheme is known to be designed to resample the discrete image data based on the least-squares method with the cubic convolution interpolation (CCI) function. It is superior in performance to other interpolation functions for digital image processing. In this paper, an improved cubic-spline interpolation (CSI) that combines the least-squares method with an eight-point cubic interpolation kernel is developed to improve the original CSI scheme. Either the FFT/Winograd DFT or the fast direct algorithm can also be used to perform the circular convolution needed in this improved CSI scheme as the original CSI scheme uses as well. Furthermore, its correlated image data and auto-correlated filter coefficients are also accurately calculated in this paper. Experimental results indicate that the proposed improved CSI scheme yields a much better quality of reconstructed image than existing interpolation algorithms including the original CSI scheme. For

an example of the gray 512*512 Lena image at same compression ratio of 4:1, the PSNR value of the reconstructed image using the proposed improved CSI scheme is higher by 2.3 dB, 1.7 dB, and 0.7 dB than linear interpolation, cubic-convolution interpolation, and the original CSI scheme, respectively.

8856-6, Session 1

Analysis of images obtained from space-variant astronomical imaging systems

Elena Anisimova, Jan Bednar, Martin Blažek, Peter Janout, Petr Pata, Karel Fliegel, Czech Technical Univ. in Prague (Czech Republic)

Most of the classical approaches to the measurement and modeling of electro-optical imaging systems rely on the principles of linearity and space invariance (LSI). In our previous research efforts we have focused on measurement and analysis of images obtained from a double station video observation system MAIA (Meteor Automatic Imager and Analyzer). The video acquisition module of this system contains wide-field input lens which contributes to the space-variant nature of the imaging system. For a precise astronomical measurement over the entire field of view, it is very important to comprehend how the characteristics of the imaging system can affect astrometric and photometric outputs. Space-variance as a property of an imaging system is studied in this paper in order to evaluate precision of astrometric and photometric results. This analysis is based on image data acquired in laboratory experiments and astronomical observations with the MAIA system. Methods for efficient calibration of this system to obtain precise astrometric and photometric measurements are also proposed.

8856-7, Session 1

Modified gradient descent method for image restoration

Artyom Makovetskii, Chelyabinsk State Univ. (Russian Federation); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada (Mexico)

In image restoration a function of two variables distorted by a known linear operator and additive noise is usually used. Numerous restoration techniques optimized with respect to different were introduced. It was shown that to solve the problem one can be used not only metrical characteristics but also topological ones of the function of two variables. Kronrod proposed to describe a function of two variables with two variations. One of them is a total variation for continuously differentiable functions. Another one is referred to as a linear variation. For continuous functions the linear variation is the sum of numbers of regular level set components for all levels. The linear variation is a topological characteristic of a function of two variables whereas the total variation that is a metrical characteristic of a function. The proposed topological method of image restoration modifies the result of the total variation-based method in order to obtain a given number of linear variations (connected components) at the output. It order to explain the ability of the proposed method to improve the restoration performance of the total variation-based method, we analyze the position of local maxima and minima of the function obtained with the gradient descent algorithm. A number of statements about the behavior of the local maxima and minima of the restored function with the total variation-based method for the case of horizontal blurring are proved. Next, we provide a formal explanation why the proposed method improves the restoration performance of the total variation-based method. Computer simulation results are provided to illustrate the performance of the proposed algorithm for restoration of degraded images.

8856-8, Session 2

Quantized embeddings: an efficient and universal nearest neighbor method for cloud-based image retrieval

Shantanu Rane, Petros T. Boufounos, Anthony Vetro, Mitsubishi Electric Research Labs. (United States)

Efficient cloud-based image retrieval requires image features that have low communication overhead, provide an accurate representation of the image, remain robust to misalignment and scale, and allowing fast cloud-based matching with minimal updates to the parameters of the client's algorithm. Most image feature spaces provide only a subset of these desired properties, and are restricted to a particular class of images; E.g., a feature space that is discriminative for searching buildings may not be as useful for discriminating medical images. Furthermore, a feature space may be discriminative for a given class of images, but may incur a large communication overhead. In this paper, we propose to extract quantized random projections of the image features under consideration, transmit these to the cloud server, and perform matching in the space of the quantized projections.

The advantage of using quantized random projections is that, once the underlying feature extraction algorithm is chosen for maximum discriminability and retrieval performance (e.g., SIFT, or eigen-features, or simply the image pixels), the random projections can guarantee a bit-rate efficient representation, as well as fast server-based matching with negligible loss in accuracy. These properties follow from the Johnson-Lindenstrauss Lemma, which states that pair-wise distances between the underlying feature vectors are preserved in the corresponding quantized embeddings.

We report experimental results of image retrieval on two image databases that employ different feature spaces, one uses SIFT features and the other uses face features extracted from the Viola-Jones face detector. For both these feature spaces, using quantized embeddings as mentioned above results in accurate image retrieval with the added advantages of bit-rate efficiency and speed of matching, even though the underlying feature spaces themselves would not have provided these advantages.

8856-9, Session 2

Cloud-based image denosing

Xiaoyan Sun, Feng Wu, Microsoft Research Asia (China); Huanjing Yue, Jingyu Yang, Tianjin Univ. (China)

Traditional image denoising methods recover a digital image from its noisy version by exploring the statistical features inside the noisy image only. They work well when a target image is slightly noisy, but unable to provide a clear result at high noise levels. In this paper, we propose a novel image denoising scheme which recovers an image by exploiting the correlations between the noisy image and the images retrieved from the Cloud. Given a noisy image, we first retrieve the relevant images based on the feature-level similarity. These images are then geometrically aligned to the noisy image to enhance the global statistical correlation. Using the aligned images as references, we recover the image by our proposed patch-level noise removal, in which the local characteristic of each noisy patch is estimated from its similar patches extracted from the references. Finally, the recovered noise free patches are blended together producing the desired noise free image. Experimental results demonstrate that our scheme achieves significant improvement compared with state-of-the-art methods in terms of both objective and subjective qualities.

8856-10, Session 2

vPresent: a cloud based 3D virtual presentation environment for interactive product customization

Xiaoming Nan, Yifeng He, Ling Guan, Ryerson Univ. (Canada)

In modern society, many companies offer customized products to their customers. There are two major challenges in providing customized products. First, product providers need to effectively present their products to the customers who may be located in any geographical area. Second, customers need to be able to provide their feedbacks on the products in real-time. However, the traditional text-based presentation cannot effectively convey sufficient information for the products or efficiently adjust product design according to customers' real-time feedbacks. In order to address the challenges, we propose vPresent, a cloud based 3D virtual presentation environment, in this paper. In vPresent, the product specialists can show the 3D virtual product to the remote customers and dynamically customize the product based on customers' feedbacks, while the customers can provide their opinions in real time when they are viewing a vivid 3D visualization of the product. Since the proposed vPresent is a cloud based system, the customers are able to access the customized virtual products from anywhere at any time, via desktops, laptops, or even smart phones. The proposed vPresent is expected to effectively deliver 3D visual information to customers and provide an interactive design platform for the development of customized products.

8856-11, Session 2

Low-delay cloud based rendering of free viewpoint video for mobile devices

Dan Miao, Univ. of Science and Technology of China (China); Wenwu Zhu, Tsinghua Univ. (China); Chang Wen Chen, Univ. at Buffalo (United States)

Free viewpoint video (FVV) provides immersive experiences in a truly seamless environment. Cloud computing facilitates the possibility to watch the FVV on mobile devices through the remote rendering in which the synthesis view is rendered in cloud server and transmitted to mobile devices. However, how to reduce the interaction delay during the viewpoint switching is a challenging problem in the remote rendering. In this paper, we propose a low-delay cloud-based FVV rendering framework to support FVV on mobile devices with satisfactory video quality and low interaction delay. In our framework, the rendering allocation scheme is proposed in which the local rendering is introduced on mobile devices during the viewpoint switching to conceal the interaction delay. To support the local rendering, the side information is generated based on the viewpoint prediction and 3D warping rule in cloud and then compressed by an edge-based coding scheme. The experiment results show that the proposed remote rendering framework can improve the quality of experience with improved free viewpoint video quality and low interaction delay on mobile devices.

8856-12, Session 2

Mobile panorama view from single picture

Hongzhi Li, Columbia Univ. (United States); Wenwu Zhu, Tsinghua Univ. (China)

Panorama view provides people an informative and natural user experience to represent the whole scene. The advances on mobile augmented reality, mobile-cloud computing, and mobile internet can enable panorama view on mobile phone with new functionalities, such as anytime anywhere query where a landmark picture is and what the whole scene looks like. To generate and explore panorama view on mobile devices faces significant challenges due to the limitations of computing capacity, battery life, and memory size of mobile phones, as well as the bandwidth of mobile internet connection. To address the challenges, this paper presents a novel cloud-based mobile panorama view system that can generate and view panorama view on mobile devices from a single picture, namely "mPano". In our system, first, we propose a novel iterative multi-modal image retrieval (IMIR) approach to get spatially adjacent images using both tag and content information from the single picture. Second, we propose a cloud-based parallel server synthing approach to generate panorama view in cloud, against today's local-client synthing that is almost impossible for mobile phones. Third, we propose predictive-cache solution to reduce latency of image delivery from cloud server to the mobile client. We have built a real mobile panorama view system and perform experiments. The experimental results demonstrated the effectiveness of our system and the proposed key component technologies, especially for landmark images.

The future of 3D and video coding in mobile and the internet

Lazar M. Bivolarski, LZ Associates (United States)

This paper presents a review of the current trends in 3D and video coding in the mobile environment and its continued fusion with the Internet. The technology advances in recent years brought increased interest in the 3D video. There is significant growth in consumer devices capable of 3D including a number of 3D cinema screens. The 3D and video are increasingly considered the most promising technologies fueling the growth of home entertainment. The technological advances and the increased market interest in turn stimulate the new research directions as well as industry efforts in standardization that capture the dynamic of this field. New video standards are emerging and being deployed to facilitate the media content delivery. Real-time collaborative environments and services make are being distributed of heterogeneous networks that use the new 3D content formats and deice rendering capabilities. New search engines and capabilities facilitate content search in a complex virtual environments. The sophisticated representation and delivery of 3D media on the Internet affects the development of new content acquisition and presentation devices that includes mobile devices as well. This environment presents new challenges for video coding of the content and opportunities for future advances.

8856-101, Session 3

Temporally coherent 4D video segmentation for teleconferencing

Jana Ehmann, Onur G. Guleryuz, FutureWei Technologies, Inc. (United States)

We develop an algorithm for 4-D (RGB+Depth) video segmentation targeting immersive teleconferencing applications on emerging mobile devices. Our algorithm extracts users from their environments and places them onto virtual backgrounds similar to green-screening. The virtual backgrounds increase immersion and interactivity, relieving the users of the system from distractions caused by disparate environments. Commodity depth sensors, while providing useful information for segmentation, result in noisy depth maps with a large number of missing depth values. By combining depth and RGB information, our work significantly improves the otherwise very coarse segmentation. Further imposing temporal coherence yields compositions where the foregrounds seamlessly blend with the virtual backgrounds with minimal flicker and other artifacts. We achieve said improvements by correcting the missing information in depth maps before fast RGB-based segmentation, which operates in conjunction with temporal coherence. Simulation results indicate the efficacy of the proposed system in video conferencing scenarios.

8856-20, Session 4

A comparison of Fisher vectors and Gaussian supervectors for document versus non-document image classification

David C. Smith, National Security Agency (United States); Keri Kornelson, The Univ. of Oklahoma (United States)

This research addresses the document vs. non-document image classification problem. The ability to accurately select document images from a data stream containing a wide variety of image types, e.g., animals, scenes, faces, etc., as well as document images intended for subsequent presentation to an OCR system is higly desirable. Without pre-selection of document images, valuable computer resources are wasted performing OCR on the non-document images, and human effort is needlessly expended or automatic queries are unnecessarily performed attempting to glean information from unintelligible OCR transcripts. This is particularly true for high volume OCR systems which process thousands of images daily. Fisher vectors represent images as gradients with respect to the parameters of a global generative probability model (e.g., a Gaussian Mixture Model, GMM) of low level image descriptors (e.g., Sift or Surf). Fisher vectors have demonstrated state-of-the-art performance for object categorization on the Caltech 256 and PASCAL VOC 2007 data sets using low cost linear SVM classifiers. A competing method, Gaussian supervectors, represent images by soft clustering the low level image descriptors according to the posterior probabilities that an observed descriptor comes from a particular Gaussian mixture. Normalized averages of the descriptors in each cluster are computed and concatenated to form a Gaussian supervector. For scene categorization, Gaussian supervectors have significantly improved upon the performance of the traditional bag-of-visual words representation. For the document vs. non-document image classification problem, we compare results obtained when a linear SVM is applied to Fisher vector and Gaussian supervector image representations. We also consider a much simpler classification scheme based only on matching local image descriptors, without recourse to visual vocabularies or generative probalistic models.

8856-22, Session 4

On selecting reference image models for anomaly detection in industrial systems

Xinhua Xiao, Jin Quan, Univ. of Cincinnati (United States); Andrew Ferro, GE Aviation Systems (United States); Chia Yung Han, Xuefu Zhou, William G. Wee, Univ. of Cincinnati (United States)

Automatic X-ray inspection of industrial parts usually uses reference-based methods, in which a set of model images or statistics extracted from the model image set are selected as the benchmark. Based on these methods, many systems are developed and are used extensively for anomaly detection. However, the performance of these systems relies heavily on the model image set. Thus, the selection of the model images is of importance. This paper presents an approach for automatically selecting a set of model images to be used in a reference-based assisted defect recognition (ADR) system for anomaly detection of turbine blades of jet engines. The proposed approach to generating a model image set is based on feature extraction. Features are extracted from callout images of the ADR system, including potential defect indication type, size and location. Experimental results show that the proposed approach is fast and a low false alarm rate with acceptable detection rate is ensured. Moreover, the approach is applicable to different blade types and varied views of the blade. Further validation shows that the approach can be applied to the update of the model image set when more images are generated from new blades.

8856-23, Session 4

Adaptive pattern for autonomous UAV guidance

Chen-Ko Sung, Florian Segor, Fraunhofer-Institut für Optronik, Systemtechnik und Bildauswertung (Germany)

The research done at the Fraunhofer IOSB in Karlsruhe within the AMFIS project is focusing on a mobile system to support rescue forces in accidents or disasters. The system consists of a ground control station which has the capability to communicate with a large number of heterogeneous sensors and sensor carriers and provides several open interfaces to allow easy integration of additional sensors into the system. Within this research we focus mainly on UAV such as VTOL (Vertical takeoff and Landing) systems because of their ease of use and their high maneuverability. To increase the positioning capability of the UAV, different onboard processing chains of image exploitation for real time detection of patterns on the ground and the interfacing technology for controlling the UAV from the payload during flight were examined. The earlier proposed static ground pattern was extended by an adaptive component which admits an additional visual communication channel to the aircraft. For this purpose different components were conceived to transfer additive information using changeable patterns on the ground. The adaptive ground pattern and their application suitability had to be tested under external influence. Beside the adaptive ground pattern, the onboard process chains and the adaptations to the demands of changing patterns are introduced in this paper. The tracking of the guiding points, the UAV navigation and the conversion of the guiding point positions from the images to real world co-ordinates in video sequences, as well as use limits and the possibilities of an adaptable pattern are examined.

Automatic defect detection in video archives: application to Montreux jazz festival digital archives

Philippe Hanhart, Martin Rerábek, Alain Dufaux, Caryl Jones, Alexandre Delidais, Touradj Ebrahimi, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Archival of audio visual data bases has become an important discipline in multimedia. Various defects are typically present in such archives. Among those one can mention recording related defects such as interference between audio and video signals, optical related artifacts, those related to recording and play out such as horizontal lines, and drop outs, as well as those due to digitization such as diagonal lines. An automatic or semi-automatic detection to identify such artifacts is useful, especially for large data bases. In this paper we propose two automatic algorithms for detection of horizontal and diagonal lines, as well as drop outs that are among the most typical artifacts. We then evaluate the performance of these algorithms by making use of ground truth scores obtained from human subjects.

8856-26, Session 4

Early forest fire detection using mid-wave and long-wave infrared cameras

John A. Saghri, Raul-Alexande Aldama, Ansel Boynton, California Polytechnic State Univ., San Luis Obispo (United States); John T. Jacobs, Raytheon Co. (United States)

Long-wave IR (LWIR) is commonly referred to as the “thermal infrared” region where thermal sources are captured without the need of, or interference from, external light/thermal sources. The mid-wave IR (MWIR) displays characteristics in between those of the thermal and reflected infrared regions, where both black-body radiation and its reflections can be detected. This paper examines the differences in the cooled MWIR and LWIR imagery obtained simultaneously from several staged test forest fires. It is shown that the resulting difference images can be effectively exploited to detect and classify heat plumes which are expelled at the early stages of the forest fire. The heat plume detection performance of this dual IR band approach is compared with that of a single IR band approach which is based on application of wavelet transform to consecutives video frames.

8856-27, Session 4

A framework for objective evaluation of privacy filters in video surveillance

Pavel Korshunov, Ecole Polytechnique Fédérale de Lausanne (Switzerland); Andrea Melle, Jean-Luc Dugelay, EURECOM (France); Touradj Ebrahimi, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

The use of video surveillance is increasing to fight against criminal and terrorist activities. At the same time, video surveillance brings various complications regarding protection of privacy of people and goods under surveillance. Several solutions have been proposed in the past to overcome if not completely, at least partially, the degree of impact on invasion of privacy, while still maintaining reasonable mechanisms for monitoring, tracking and surveillance.

In this paper, we propose a new framework for objective evaluation of privacy filters, as en extension of a prior work based on subjective evaluation. After a discussion of the architecture and process for the objective evaluation, the performance of the proposed approach is compared to subjective evaluations from various points of views, and conclusions are drawn.

8856-28, Session 4

Video coding standards performance comparison

Lazar M. Bivolarski, LZ Associates (United States)

Comparing of video codecs has been a subject of many studies of the years. Various parameters and content are used to extract performance of the codecs for specific environments and use cases. The performance evaluation is usually centered on common test conditions to minimize the variation in the interpretation of the results. The overall quality then is measured as relation between the compression the compression ratio the absolute arithmetic difference measured with PSNR. This paper analyses the comparison between different coding schemes and compares the quality as the function of the coding scheme complexity and the relative content complexity. The normalization of both complexities and the coding efficiency with PSNR then will represent a better basis of comparison between the codding schemes since it will include the cost of the efficiency achieved via specific coding scheme. The paper analyses the various quality metrics and presents the value of specific quality metric applicability in the corresponding use cases.

The comparing of different coding schemes is presented using over the same content without a need for synchronized test conditions due to the content and coding scheme the complexity normalization.

8856-29, Session 5

Analysis of view synthesis prediction architectures in modern coding standards

Dong Tian, Feng Zou, Mitsubishi Electric Research Labs. (United States); Chris Lee, National Cheng Kun University (Taiwan); Anthony Vetro, Mitsubishi Electric Research Labs. (United States); Huifang Sun, Mitsubishi Electric Research Labs (United States)

Depth-based 3D formats are currently being developed as extensions to both AVC and HEVC standards. The availability of depth information facilitates the generation of intermediate view points for advanced 3D applications and displays, and also enables more efficient coding of the multiview input data through view synthesis prediction techniques. This paper outlines several approaches that have been explored to realize view synthesis prediction in modern video coding standards such as AVC and HEVC. The benefits and drawbacks of various architectures are analyzed in terms of performance, complexity, and other design considerations.

8856-30, Session 5

Neighboring block based disparity vector derivation for multiview compatible 3D-AVC

Jewon Kang, Ying Chen, Li Zhang, Xin Zhao, Marta Karczewicz, Qualcomm Inc. (United States)

3D-AVC, which is being developed under JCT-3V, significantly outperforms the Multiview Video Coding plus Depth (MVC+D), which doesn't have new macroblock level coding tools compared to Multiview video coding extension of H.264/AVC (MVC). However, when configuring 3D-AVC to support multiview compatibility, texture views are decoded without depth information, and the performance of the current 3D-AVC becomes only comparable to MVC+D. The problem is caused by the lack of disparity vectors between views which can be converted only from depth views in 3D-AVC. In this paper, an efficient disparity vector derivation method utilizing only the information of texture views is proposed. Motion information of neighboring blocks is used to determine a disparity vector for a macroblock, and the derived disparity vector is efficiently used for existing coding tools in 3D-AVC. The proposed method enables increasing the performance of 3D-AVC in the multiview compatible mode substantially, about 20% bit-rate reductions for texture coding.

8856-31, Session 5

Depth estimation from multiple coded apertures for 3D interaction

Sungjoo Suh, Changkyu Choi, Dusik Park, Samsung Advanced Institute of Technology (Korea, Republic of)

In this paper, we propose a novel depth estimation method from multiple coded apertures for 3D interaction. A flat panel display is transformed into lens-less multi-view cameras which consist of multiple coded apertures. The sensor panel behind the display captures the scene in front of the display through the imaging pattern of the modified uniformly redundant arrays (MURA) on the display panel. To estimate the depth of an object in the scene, we first generate a stack of synthetically refocused images at various distances by using the shifting and averaging approach for the captured coded images. And then, an initial depth map is obtained by applying a focus operator to a stack of the refocused images for each pixel. Finally, the depth is refined by fitting a parametric focus model to the response curves near the initial depth estimates. To demonstrate the effectiveness of the proposed algorithm, we construct an imaging system to capture the scene in front of the display. The system consists of a display screen and an x-ray detector without a scintillator layer so as to act as a visible sensor panel. Experimental results confirm that the proposed method accurately determines the depth of an object including a human hand in front of the display by capturing multiple MURA coded images, generating refocused images at different depth levels, and refining the initial depth estimates.

8856-32, Session 5

Automatic camera to laser calibration for high accuracy mobile mapping systems using INS

Werner Goeman, Grontmij Belgium NV (Belgium); Koen Douterloigne, Sidharta Gautama, Univ. Gent (Belgium)

A mobile mapping system (MMS) is a mobile multi-sensor platform developed by the geoinformation community to support the acquisition of huge amounts of geodata in the form of georeferenced high resolution images and dense laser clouds. Since data fusion and data integration techniques are increasingly able to combine the complementary strenghts of different types of sensors, the external calibration of a camera to a laser rangefinder is a common pre-requisite on today's mobile platforms. The methods of calibration are often poorly documented, are time-consuming, demand expert knowledge and often require a carefully constructed calibration environment.

A new methodology is studied and explored to provide a high quality external calibration for a camera to a laser range finder which is automatic, easy to perform, robust and fool proof.

The positioning system used on the mobile platform is an Applanix POSLV 420, the mounted camera is a Point Grey color video camera, the laser is a 2D RIEGL LMS-Q120, both synchronized with the POSLV 420 system. The method presented here, uses a portable, standard ranging pole which needs to be positioned on a known ground control point. For calibration, a well studied absolute orientation problem needs to be solved. In this study, the use of the inertial relative movements will be explored to collect more useful calibration data. This results in a better intersensor calibration allowing better coloring of the clouds and a more accurate depth mask for images, especially on the edges of objects in the scene.

A few benchmarking tests are done under various lighting conditions which proves the methodology's robustness, by showing subpixels accuracy for projected laser data on the images.

8856-33, Session 5

Obliquity effect removal in 3D object reconstruction

Luis David Lara-Rodríguez, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Elizabeth López Meléndez, INAOE (Mexico); Gonzalo Urcid Serrano, Estela López Olazagasti, Eduardo Tepichin Rodríguez, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

We have been working in the reconstruction of 3D objects, using the reflectivity of the material to obtain the depths with Gaussian models. In this kind of reconstruction there is a problem of obliquity outside the paraxial area due to the nature of the source. To solve this obliquity problem, we use the Phong's illumination model and the angular aperture of the source to compensate it. In our approach we take two images of a planar object at different distances so the system can calculate the compensation mesh to rebuild the object and thus eliminate this obliquity of the reconstructed object. We present comparisons of this improved method against Gaussian models and reconstructions using the LFS system.

8856-34, Session 5

8856-35, Session 5

Single pass image warping method with anisotropic filter

Vladimir Lachine, Gregory Smith, Louie Lee, Qualcomm Inc. (Canada)

Conventional image capture and display devices are prone to various form of optical artifacts. These artifacts are inherent to the none ideal behavior of the various optical elements such as sensors, displays, lens, prisms, mirrors, light sources. These optical distortions may be corrected digitally by image warping technology.

Image warping may be defined as a process of dynamically resampling a regularly spaced input image to produce a none regular spacing output image.

In this paper, one-pass algorithm for digital image warping is presented. It is based on anisotropic circularly symmetric antialiasing filtering over elliptical or rectangular footprint. It is shown that developed design provides flexibility and better image quality than known two-pass methods. The proposed algorithm may be embedded into display processor for optical distortion corrections both at image acquisition and displaying sides. It includes luminance and chromaticity non-uniformity correction as well.

Low complexity video coding using SMPTE VC-2

Tim Borer, British Broadcasting Corp. (United Kingdom)

This paper describes the recently standardized High Quality, “HQ” profile of the SMPTE VC-2 codec, designed for low complexity and low latency applications. It presents experimental results for a selection of low complexity coding parameters for both RGB and YCbCr (4:4:4) coding. VC-2 HQ’s motivating application was video production and archiving, but it can also embrace other applications such as texture coding, high dynamic range, and lossless coding.

VC-2 HQ is an intra frame wavelet codec. It supports a range of coding parameters such as a choice of wavelet kernels, wavelet depths and size of coded image region (analogous to the transform size in a block transform codec). This paper specifically investigates the low complexity coding parameters of 2 and 3 level Haar and LeGall wavelet kernels, for image regions of 4x4 and 8x8 pixels.

Whereas texture codecs typical target a fixed compression ratio with limited bit depth, VC-2 HQ provides greater flexibility supporting compression ratios from 8:1 to lossless coding at greater bit depth. This paper focuses on the design choices made for low complexity, such as the absence of prediction and the type of entropy coding. Results are presented showing the effect of some of these choices. It also describes the partitioning of wavelet coefficient, which is different from a block transform codec. This allows it support a simple quantization scheme, thereby avoiding buffering and facilitating low latency. The resulting spatially varying quantization exploits psychovisual masking and supports coding higher dynamic range signals.

8856-38, Session 6

Performance evaluation of phase-based correspondence matching on GPUs

Mamoru Miura, Tohoku Univ. (Japan); Kinya Fudano, NEC Corp. (Japan); Koichi Ito, Takafumi Aoki, Hiroyuki Takizawa, Hiroaki Kobayashi, Tohoku Univ. (Japan)

Image correspondence is one of the important key techniques in many fields such as image sensing, video signal processing, computer vision, etc. Especially, 3D measurement using stereo vision requires an accurate stereo correspondence algorithm, since the accuracy of 3D measurement depends on that of image correspondence between a stereo image pair. The computation time of image correspondence is also important in practical applications of 3D measurement using stereo vision.

To achieve high-accuracy 3D measurement, we have proposed a high-accuracy stereo correspondence matching method using Phase-Only Correlation (POC). Using our method, we have also developed a passive 3D measurement system, whose accuracy is comparable with active 3D measurement systems. On the other hand, the application range of POC-based correspondence matching is limited, since many corresponding point pairs are required for measuring fine 3D structure of an object even though the computational cost of POC-based correspondence matching is high.

Addressing this problem, we propose a Graphics Processing Unit (GPU) implementation of the POC-based correspondence matching method and implementation techniques for GPU architecture. Through experiments using a variety of GPUs of different vendors and architecture, we demonstrate that the proposed approach is high-speed and high-efficiency compared with the CPU implementation and provide a detailed performance analysis of the GPU implementation. We also develop a real-time 3D measurement system using the proposed approach and demonstrate its effectiveness.

8856-39, Session 6

Comparison of CPU and GPU based coding on low-complexity algorithms for display signals

Thomas Richter, Univ. Stuttgart (Germany); Sven Simon, Department of Parallel Systems, University of Stuttgart (Germany)

Graphics Processing Units (GPUs) are freely programmable massively parallel general purpose processing units and thus offer the opportunity to off-load heavy computations from the CPU to the GPU. One application for GPU programming is image compression, where the massively parallel nature of GPUs promises high speed benefits. This article analyzes the predicaments of data-parallel image coding on the example of two high-throughput coding algorithms designed particularly for the online-compression of monitor signals. The codecs discussed here, a wavelet based SPIHT codec and a Hadamard based embedded codec, were designed to answer a call from the Video Electronics Standards Association (VESA), and require only minimal buffering at encoder and decoder side while avoiding any pixel-based feedback loops limiting the operating frequency of hardware implementations.

Comparing CPU and GPU implementations of the codes show that GPU based codes are usually not considerably faster, or perform only with less than ideal rate-distortion performance. Analyzing the details of this result provides theoretical evidence that for any coding engine either parts of the entropy coding and bitstream build-up must remain serial, or rate-distortion penalties must be paid when offloading all computations on the GPU.

8856-40, Session 6

Compact opto-electronic engine for high-speed compressive sensing

James Tidman, Tyler Weston, Donna Hewitt, Matthew A. Herman, Lenore McMackin, InView Technology Corp. (United States)

The resource efficiency of compressive sensing (CS) enables the computational construction of images from far fewer measurements than what is usually considered necessary by the Nyquist–Shannon sampling theorem. There is now a vast literature around CS mathematics and applications since the development of its theoretical principles about a decade ago that includes quantum information to optical microscopy to seismic imaging. In the application of shortwave infrared imaging, we have developed cameras based on the CS "single-pixel" camera architecture. This architecture comprises an objective lens to image the scene onto a Texas Instruments DLP micromirror array (DMD), which by modulating the image with its individually controllable mirrors, projects the image onto a selected basis set. Optics following the DMD collects and focuses the image on the detector. We have also developed higher frame rate cameras with a similar architecture that utilize multiple detectors working in parallel.

While the design of a CS camera is straightforward conceptually, its bench top implementation is a project that requires significant development efforts in optics, electronics, hardware and software, particularly if high efficiency and high-speed operation are required. We describe development of a high-speed CS engine in the form of a lab-ready workstation where custom measurement patterns are loaded at speeds up to 32kHz and custom reconstruction algorithms can be quickly implemented in experiments. Our work includes optical path design, FPGA's for DMD pattern generation, and circuit boards for front end data acquisition, ADC and system control packaged in a compact workstation.

8856-42, Session 6

Joint estimation and tracking of objects in a single camera using EM-EKF

Pristley Sathyaraj, Henry Leung, Univ. of Calgary (Canada)

Tracking objects in dynamic scene is an interesting area of research and it has applications in many areas like surveillance, missile tracking system, virtual reality and robot vision. Objects in real world exhibit complex interactions with each other. When captured in a video signal, these interactions manifest themselves as intertwining motions, occlusion and pose changes. A video tracking system should track these objects in this complex interactions smoothly. This paper presents a new joint method for tracking moving objects in outdoor and indoor environment. This joint method uses recursive expectation-maximization (EM) incorporated with Extended Kalman Filter (EKF) to estimate, fuse and track the object simultaneously than doing it in two different steps. This combined approach provides more realistic solution to the problem by including all the parameters in state variables and assigning the track based on the likelihood of the objects position. Thereby, outperforming the conventional method of treating it as two different problems. We have tested our algorithm with standard data set and real time video sequences collected from indoor environment. On testing this algorithm with PETS 2001 data set we find that 14 out of 17 objects are accurately tracked with the accuracy of 82% and Occlusion Success Rate (OSR) of 75% with frames processed at a rate of 25fps. With real time video sequence, our approach successfully tracks the objects with occlusions with tracking accuracy of 95% and OSR of 80%. This method successfully tracks objects with occlusions, orientations and intertwining motion with better accuracy and low computational cost.

8856-43, Session 6

A fast kernel tracking algorithm based on local gradient histograms

Daniel Miramontes-Jaramillo, Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada (Mexico)

The tracking task in a video sequence has many and diverse approaches, and so many ways to solve it. Many different problems are usually solved: detection and localization of the tracked object in the scene, invariance to different movement directions of the object, situations when the object goes in and out the scene, occlusion and so on. The first thought for solving it could be to run an image matching algorithm over every frame of the sequence. However, nowadays the frame rates are as low as 30 FPS (frames per second) to as high 300 FPS in special devices as high speed cameras; so, solving an image matching problem at least thirty times per second is a tiresome and costly task for any machine. To reduce processing, memory and time costs, many algorithms have been proposed. These algorithms can be classified as follows: point trackers, kernel trackers, and silhouette trackers. Point trackers take advantage of repeatable interest points over the first frames of the sequence, allowing the extraction of information about direction as well as speed. Kernel trackers use sliding windows to locate the object using histograms and other area information techniques; once the object is located the search area is reduced to that of the neighborhood of the object. The silhouette trackers extract the information to the contour of the object and follow this contour over the frame sequence. In this work, we propose a kernel tracking algorithm based on a local gradient histogram's matching algorithm and recursive calculation of the object position over the video sequence.

8856-44, Session 6

Real-time object tracking using digital correlation filtering and state prediction

Viridiana Contreras, Victor H. Díaz-Ramírez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada (Mexico); Juan J. Tapia-Armenta, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico)

A real-time tracking system based on adaptive correlation filtering, is proposed. The system is able to estimate at high-rate the position of a given target at any time instant by taking into account information of past and present scene-frames. The position of the target is estimated with the help of a bank of composite correlation filters with complex constraints, trained with an iterative algorithm. The filter bank, is applied to a small region of the observed scene that is updated at each frame according to a state predictor which is based on the motion model of the target in a two-dimensional plane. Furthermore, the filter bank is able to modify the number of required filters for each frame in order to reduce computational complexity. The proposed system is implemented on a graphics processing unit to take advantage of massive parallelism. As result, we can perform object tracking in real-time. Computer simulation results obtained with the proposed system in synthetic and real noisy scenes, are presented and discussed in terms of tracking accuracy and real-time operation efficiency. Tracking accuracy is characterized by discrimination capability and location errors, whereas real-time operation efficiency is measured by the average processed frames per second.

8856-45, Session 7

QoE for telemedicine: challenges and trends

Patrick Le Callet, Zhang Ge Lu, Univ. de Nantes (France); Christine Cavaro-Ménard, Ctr. Hospitalier Univ. de Angers (France)

To really improve the access, efficiency, effectiveness and quality of clinical processes, telemedicine, with the sharing of digital data (i.e. physiological signals, 2D/3D images and videos) should adhere to the same standards of quality and usability, as that in traditional healthcare. This paper proposes a survey of some key issues and trends associated to an emerging quality measurement called Quality of Experience (QoE) in telemedicine. Although, the quality of services (QoS) in telemedicine has been quite investigated of late, the QoE is in its infant's age and should not be assimilated to QoS. Considered as the most important factor adoption of telemedicine, QoE studies should be conducted with an appropriate methodology incorporating user involvement and digital data and their relation with QoS should be identified.

We first present the services offered by telemedicine and underline the significance of QoE for tele-diagnosis and tele-surgery including digital data from different acquisition modalities. Next, we identify and analyze the influencing factors such as application area, application purpose (emergency care, acquisition assistance, second opinion, education...), content type (data specificities depending on acquisition modality), context of use (offline/real time, interactivity...), and user's state (stress, expertise...), that we have to consider for a relevant QoE measurement in telemedicine. At last, we present different solutions in the framework of QoE measurement including offline tools for benchmarking (oriented Perceptual Difference Model, Model Observer) and real time tools for monitoring (video and audio quality assessment with full-reference metrics and parametric metrics).

8856-46, Session 7

Classification of microcalcifications using micro-CT

Frederik Temmermans, Bart Jansen, Vrije Univ. Brussel (Belgium); Inneke Willekens, Univ. of Brussels (Belgium); Elke Van de Casteele, Univ. Antwerpen (Belgium); Rudi Deklerck, Peter Schelkens, Vrije Univ. Brussel (Belgium); Johan De Mey, Univ. Ziekenhuis Brussel (Belgium)

Microcalcifications are tiny spots of calcium deposit that often occur in female breasts. Microcalcifications are common in healthy woman, but they often are an early sign of breast cancer. On a mammogram, the current standard of care for breast screening, calcifications appear as tiny white dots. They may occur scattered throughout the breast or grouped in clusters. Radiologists determine the suspiciousness based upon several factors, including position, frequency, grouping, evolution compared to prior studies and shape. In this paper, we study micro-CT images of biopsy samples containing microcalcifications. The scanner delivers 3D images with a voxel size of 12µm, i.e. ca. 8 times the spatial resolution of a contemporary digital mammogram. We propose an automated binary classification method of the samples, based upon shape analysis of the microcalcifications. The study is performed on a set of 50 benign and 50 malign samples preserved in paraffin. The ground truth of the classification is based upon anapathological investigation of the paraffin blocks.

8856-47, Session 7

Motion compensation of optical mapping signals from isolated beating rat hearts

Birgit Stender, Floris Ernst, Univ. zu Lübeck (Germany); Bo Wang, Zhenxi Zhang, Xi'an Jiaotong Univ. (China); Alexander Schlaefer, Univ. zu Lübeck (Germany)

Introduction

Optical mapping is a well established technique for recording monophasic action potential traces on the epicardial sur-face of isolated hearts, [1]. This measuring technique offers a high spatial resolution but it is sensitive towards myocar-dial motion. Motion artifacts occur because the mapping between a certain tissue portion sending out fluorescent light and a pixel of the photodetector changes over time. So far this problem has been adressed by suppressing the motion or ratiometric imaging, [2, 3]. We developed a different approach to compensate the motion artifacts based on image registration.

Methods

Five rat hearts were excised and stained with Di-4-ANEPPS during cardioplegia. They were brought to beating auton-omously before current-controlled stimulation was applied at the apex. After 20 minutes 2,3-Butanedione Monoxime (BDM) was given for mechanical uncoupling. Light emitting diodes were used for excitation (peak wavelength at 530 nm). Optical mapping data in all three phases was recorded with a sCMOS camera (295 fps, long pass emission filter at 610 nm). The cardiac motion was determined from the images in two steps: First the translation and shearing were determined using a 2D affine registration algorithm. Afterwards the deformation was calculated with a nonrigid demon's algorithm, [4].

Results

We compared traces of the motion compensated fluorescence difference signal with traces recorded after applying BDM. We could determine a significant reduction of motion artefacts.

Conclusion

Optical mapping of rat hearts in combination with optical motion tracking makes it possible to monitor both myocardial motion and excitation propagation with high spatial resolution.

Automated estimation of hip prosthesis migration: a feasibility study

Jef Vandemeulebroucke, Rudi Deklerck, Frederik Temmermans, Vrije Univ. Brussel (Belgium); Gert Van Gompel, Nico Buls, Thierry Scheerlinck, Johan de Mey, Univ. Ziekenhuis Brussel (Belgium)

A common complication associated with hip arthoplasty is prosthesis migration, and cemented components with a migration greater than 0.85mm within the first six months after surgery, are an indicator for prosthesis failure.

Currently, prosthesis migration is evaluated using X-ray images, which can only estimate migrations larger than 5mm.

We propose an automated method for estimating prosthesis migration more accurately, using CT images and image registration techniques. We report on the results obtained using an experimental set-up, in which a metal prosthesis can be translated and rotated w.r.t. a cadaver femur, over distances and angles, applied using a combination of positioning stages. 30 high-resolution helical CT images were acquired for prosthesis translations ranging from 0.05mm to 4mm, and rotations ranging from 0.3° to 3°.

Images are first preprocessed to reduce artifacts. Bone and prosthesis are extracted using consecutive thresholding and morphological operations. Two registrations are performed, one aligning the bones and the other aligning the prostheses. The migration is estimated as the difference between the found transformations. We use a robust, multi-resolution, stochastic optimization approach, able to deal with the metal artifacts, and compare the sum of squared differences (SSD) to mutual information (MI).

For the translations, the mean 3D error was found to be 0.2mm for SSD, and 0.15mm for MI. For rotations, the standard deviation of the estimation error was 0.18° for SSD, and 0.08° for MI. The results show that the proposed approach is feasible. Clinical validation studies on patient images will now be undertaken.

8856-49, Session 7

Motion estimation and segmentation in CT cardiac images using the Hermite transform and active shape models

Boris Escalante-Ramírez, Ernesto Moya-Albor, Barba J. Leiner, Enrique Vallejo, Fernando Arambula, Univ. Nacional Autónoma de México (Mexico)

Considering the importance of studying the movement of certain cardiac structures such as left ventricle and myocardial wall for better medical diagnosis, we propose a method for motion estimation and image segmentation in sequential 3D Computed Tomography images. Two main tasks are tackled. The first one consists of a method to estimate the heart's motion based on a bio-inspired image representation model. Our proposal is based on the polynomial decomposition of each of the sequence images using the steered Hermite transform as a representation of the local characteristics of images from a perceptual approach within a multiresolution scheme. The Hermite transform is a model that incorporates some of the more important properties of the first stages of the human visual system, such as the overlapping Gaussian receptive fields, the Gaussian derivative model of early vision and the multi-resolution analysis. We propose an approach for optical flow estimation that incorporates image structure information extracted from the steered Hermite transform coefficients that is later used as local motion constraints in a differential estimation approach. The second task deals with cardiac structure segmentation in time series of 3D cardiac images based on deformable models. The goal is to extend active shape models (ASM) of 3D objects to the problem of 4D (3D + time) cardiac CT image modeling. The segmentation is achieved by constructing a point distribution model (PDM) that encodes the spatio-temporal variability of a training set. An active search is used in the segmentation process where an initial approximation of the spatio-temporal shape is given and the gray level information in the neighborhood of the landmarks is analyzed. The starting shape is capable of deforming so as to better fit the data, but in the range allowed by the point distribution model. Combination of both motion estimation and image segmentation allows isolating motion in cardiac structures of medical interest such as ventricle walls.

8856-50, Session 7

Midbrain volume segmentation using active shape models and LBPs

Jimena Olveres, Rodrigo Nava, Boris Escalante-Ramírez, Univ. Nacional Autónoma de México (Mexico); Gabriel Cristóbal, Consejo Superior de Investigaciones Científicas (Spain); Carla María García-Moreno, Hospital Ángeles Lomas (Mexico)

Midbrain or mesencephalon is an approximately 2x2x1 cm sized region near the center of the brain that serves as a relay center for visual, auditory, and motor system information. Due to the fact that the most common illness associated with this region is Parkinson's disease, midbrain segmentation has become an important issue in neurological applications. Recently, Magnetic Resonance Imaging (MRI) has been used to detect different brain structures such as midbrain, white matter, grey matter, corpus callosum, and cerebellum due to the good offered resolution and the advantage to obtain different image modalities (for instance, T1 or T2 weighted modes). The first step to analyze Parkinson's disease is midbrain segmentation. So far, Active Shape Models (ASM) have been extensively used in literature for organ segmentation where the shape can be used as a discriminant feature. However, fine adjustments can be improved using Local Binary Patterns (LBP), originally proposed by Ojala. In this paper we propose a novel method based on the combined used of ASM and LBPs. The joint-model results outperform the final segmentation because it considers both global and local statistics provided by ASM and labeled LBP histograms, respectively. Furthermore, we evaluate different LBP algorithms to asses the best implementation for the midbrain segmentation. Comparatives will be done using the classical ASM approach and our different ASM+LBP schemes.

8856-51, Session 7

Real time contact-free and non-invasive tracking of the human skull: first light and initial validation

Floris Ernst, Ralf Bruder, Tobias Wissel, Patrick Stüber, Benjamin Wagner, Achim Schweikard, Univ. zu Lübeck (Germany)

In an increasing number of fields in medicine, precise and fast localisation of bony targets inside the body is essential. Up to now, exact localisation in the operation room can either be done with invasive methods like X-ray imaging and electromagnetic tracking systems, with volumetric ultrasound or by fixing the target in place. In this work, we present a new technology to directly track the position of the human skull through tissue in real time using infrared lasers.

To achieve this, an experimental setup has been developed to precisely target a position on a subject's skin with an 850 nm laser. The primary reflection on the skin is triangulated using a high-speed camera. Additionally, the reflections as well as in-tissue scattering are recorded with an in-beam setup of a NIR sensitive high-speed and high-resolution camera. Consequently, it is possible to record the scattering patterns specific to the composition of the tissue at the target.

We have recorded MRI data of three test subjects (voxel size 0.15 x 0.15 x 1mm?) and extracted the soft tissue thickness with a semi-automatic segmentation approach. The MRI data was validated using force-controlled 2D ultrasound (tracked by an optical tracking system), from which soft tissue thickness was segmented manually. Optical measurements and MRI data were registered to determine soft tissue thickness for each measured laser target and finally used to train a support vector regression machine.

Using the optical setup, we succeeded in computing the soft tissue thickness on the subjects' foreheads with sub-millimetre accuracy.

8856-52, Session 7

Optical system to compute intensity moments for gait description

Carina Toxqui Quitl, Victoria M. Morales-Batalla, Alfonso Padilla-Vivanco, Univ. Politécnica de Tulancingo (Mexico)

A hybrid optical-digital processor for gait description is presented. The processor computes invariant moments of an image by spatial convolution with a single mask. The invariant moments are independent of shift and rotation. An invariant moment history (MH) is obtained from N-frames to describe the history shape of individuals. The feature gait

extraction for each subject is a difficult problem because the starting point of the gait cycles or MH is different for the same subject. Also, the same subject do not walk at the same way in each sample, thus will be required to choose the better sequences which can be set on phase. A method to calculate the temporal correlation in terms of a moment function representation of lower body images for gait recognition is presented. The starting point of the gait cycles is solving through Genetic Algorithms. Descriptors are obtained by selected MHs in phase. By using the combined metrics of correlation and minimum distance classifier M-classes, fitting only the selected features in order to obtain the highest Correct Classification Rate (CCR). The databases used here are MoBo, CASIA A, and our home database. In general, we see that the proposed algorithm has good performance in the three databases.

8856-53, Session 7

3D surface reconstruction based on image stitching from gastric endoscopic video sequence

Mengyao Duan, Rong Xu, Jun Ohya, Waseda Univ. (Japan)

Gastric endoscope is a very essential tool used for examining any gastric abnormalities or growths. It is a flexible fiber-optic scope with a light that helps a physician see inside certain internal organs. However, gastric endoscopy can only provide a narrow view angle and 2D structures of the internal organs. In order to expand the view angle and describe the details of 3D organ structures, we propose an approach to reconstruct 3D gastric surface based on image stitching from an endoscopic video sequence.

The proposed method consists of the following three steps: (1) 3D reconstruction, (2) 3D point cloud stitching and (3) dense point cloud creation. In the beginning, we separate one video sequence into image groups, each of which consists of two frames, where subsequent two groups share one overlapping frame as stitching region. Then, in (1), the 3D point cloud of each group is reconstructed by utilizing structure from motion (SFM). Next, in (2), SIFT feature based algorithm registers and stitches the 3D point clouds obtained in (1), by estimating the transformation matrix of the overlapping frame (stitching region) in the two subsequent groups with a high accuracy and efficiency. Finally, in (3), we select the most robust SIFT feature points as the seed points, and then obtain the dense point cloud from sparse point cloud through a depth testing method presented by Furukawa. Consequently, dense points, threefold in size, in all the groups are combined together so that the entire 3D gastric structures are obtained.

Experimental results demonstrate that the proposed method achieves a satisfied accuracy and efficiency for the 3D reconstruction of gastric surface from an endoscopic video sequence, and promise a large view angle.

8856-63, Session PWed

Combination of graph theoretic grouping and time-frequency analysis for image segmentation with an example for EDI-OCT

Raheleh Kafieh, Hossein Rabbani, Isfahan Univ. of Medical Sciences (Iran, Islamic Republic of)

We introduce a nonparametric approach to multiscale segmentation of images using a hierarchical matrix analysis framework called diffusion wavelets that tries to benefit from the advantages of both graph theory and wavelet transform. Till now a broad range of multiscale transforms like wavelets (and other x-lets) have been introduced for image segmentation task. Furthermore, graph theoretic formulation of grouping is also well-known to deal with this problem. The combination of multiscale transforms and graph based partitioning results in a scale-spectral method exploring through different scales of the image, over a great deal of spectral methods in graph partitioning. The method constructs multiscale basis functions and a series of dilation and orthogonalizations build a hierarchy, automatically. At each level, a set of basis functions is build by applying dyadic powers of a diffusion operator on the basis at the lower level. Two approaches are proposed for multiscale segmentation of images using diffusion wavelets. The first method is based on extended basis functions at each level and designing a competition between the basis value for partitioning. The second approach is defining a new distance for each level and clustering based on such distances. An example of application in Enhanced Depth Imaging Optical Coherence Tomography (EDI-OCT) is shown in this paper. The retinal structure containing inner, outer and choroidal layers of retina are segmented apart from the background by applying diffusion wavelet in a scale that produces 3 clusters.

Real-time detection of respiration rate with non-contact mode based on low-end imaging equipment

Xiaoli Jin, Liquan Dong, Yuejin Zhao, Xiaohua Liu, Ming Liu, Hong Wu, Lei Yang, Beijing Institute of Technology (China)

Standard instrumentation for the assessment of respiration rate is large and based on invasive method, and not suitable for daily inspection. An optical, simple and non-contact measurement method to detect human respiration rate using low-end imaging equipment is discussed. This technology is based on the visible light absorption of blood, which contains many important physiological information of the cardiovascular system. The light absorption of facial area can be indirectly reflected to gray value of the corresponding area image. In this paper, we acquire the respiration rate though the video signal captured by low-end imaging equipment. Firstly, the color CCD captures the facial area below the eyes and every frame of the video can be separated into three RGB channels. The blue channel is extracted as the research object. Then, we calculate the mean gray value for each image and draw the mean gray curve along the time. Fourier transform can get the frequency spectrogram of the graph, which is filtered through the Fourier filter. The extreme point is the value of the respiratory rate. Finally, an available interface program is designed and we have some volunteers tested. The correlation coefficient between the experimental data and the data provided by a reference instrument is 0.98. The consistency of the experimental results is very well. This technology costs so low that it will be widely used in medical and daily respiration rate measurement.

Fractal evaluation of drug amorphicity from optical and scanning electron microscope images

Gheorghe Gavriloaia, Univ. of Pitesti (Romania); Bogdan-Mihai Gavriloaia, Radu Vizireanu, Univ. Politehnica of Bucharest (Romania); Catalin Neamtu, Univ. of Pitesti (Romania)

The assessment chemical, structural, energetic, and physical aspects of pharmaceutical compounds have to be done since the preformulation stage. Amorphous materials are metastable, and more reactive than crystalline. Detection, quantification and characterization of amorphous content given by random supramolecular arrangement are analyzed in this paper. Amorphicity is interpreted as a spatial chaos and fractal geometry is used to study patterns of molecular aggregates on solid micron-sized structures. Eleven images of dexamethasone were taken, 3 from an optical microscope, OM, enlarging from 40 to 1000, and 8 from a scanning electron microscope, SEM, which magnifies between 600 and 80000, all of them having the same resolution. At each scale, black and white images were generated by using a variable threshold in the range 0-255. The magnification and threshold influences of fractal dimension, FD, were investigated. 200 layers of grids of decreasing boxes were put over the images at each scale and threshold, and counted how

many boxes in each grid were black, white or black and white. FD corresponds to the slope of the logarithmic regression line for number of boxes and their dimension. The average FD for pattern irregularities of OM images was 1.538, and about 1.692 for SEM images. The FDs of the two kinds of boxes: black and white are less sensitive of threshold. 3D images were shown to illustrate dependence of FD of threshold and magnification level. As a result, the OM image at a single scale is enough to characterize the drug amorphicity.

8856-66, Session PWed

Automatic detection of micro-aneurysms in retinal images based on curvelet transform and morphological operations

Shirin Hajeb, Hossein Rabbani, Isfahan Univ. of Medical Sciences (Iran, Islamic Republic of)

Diabetic retinopathy (DR) is one of the major complications of diabetes and Micro-aneurysms (MAs) are one of the first pathologies associated with DR. The number and the location of MAs are very important in grading of DR. In this paper we use Fundus Fluorescin Angiography (FFA) for extracting MAs. Our new method is based on curvelet transform and morphological operations. As vessels and MAs are the bright parts of FFA image, firstly vessels must be removed from FFA image. For this reason, after applying a curvelet-based contrast enhancement method on inverted FFA image, the curvelet coefficients of the match filtered response of enhanced image are obtained, then low frequency component is removed, and other coefficients are amplified. By thresholding of reconstructed image and applying length filtering, misclassified pixels are removed and vessels are extracted. After removing the extracted vessels from the FFA image, morphological operations are applied on resulted image for detecting MAs. For this reason, at first the image is dilated in order to produce an image in which MAs appear brighter than other pixels. By erosion of resulted image, the background of retina is obtained. In the next step the background is removed from dilated image, bright small regions are enhanced and finally MAs are detected by thresholding.

8856-67, Session PWed

A new approach to tunnel image acquisition using a fisheye lens camera

Gihong Kim, Gangneung-Wonju National Univ. (Korea, Republic of); Junhee Youn, Hyun Sang Choi, Myung Jin Chae, Korea Institute of Construction Technology (Korea, Republic of)

Different types of information are required for improving work efficiency and safety in construction sites. Among numerous information sources, digital images have been largely used because they are easily available and include various information. However, it is difficult to obtain visual information from linear structures like tunnels using regular photogrammetric methods due to their structural characteristics. In this case, some studies on using linescan cameras or laser scanners have already introduced.

In this research, we proposed a tunnel image acquisition method using a fisheye lens, which is a type of super-wide-angle lens. A fisheye image covers the whole hemispherical field of tunnel in front of the camera through the wide angle of the lens. We took pictures of a tunnel using a fisheye lens camera along the moving direction. Then the cylindrical projection transformation was applied to them for producing rectangular images. Also, we analyzed the distortions generated by the characteristics of the lens and the transformation process, and a calibration equation was derived by mathematical models according to types of distortions. We implemented this approach in a program using Visual C++. Thus, tunnel mosaic images were constructed using fisheye images of actual tunnels based on this program, the condition of tunnel walls can be monitored through these mosaic images. Although the proposed method shows some degrees of uncertainty about calibrating distortions and is limited by the moderately low resolution in images, it could be applicable in terms of reducing working hours in-site monitoring and requiring relatively low cost.

Scale-selective wavelet analysis of polarization images of biological polycrystalline net

Taras Boychuk, Bukovinian State Medical Univ. (Ukraine); Alexander Ushenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Ozar Mincer, Viktor Bachinskiy, Olexander Wanchuliak, Bukovinian State Medical Univ. (Ukraine)

The optical model of polycrystalline networks of myocardium protein fibrils is presented. The technique of determining the coordinate distribution of polarization azimuth of the points of laser images of myocardium histological sections is suggested. The results of investigating the interrelation between the values of statistical (statistical moments of the 1st-4th order) parameters are presented which characterize distributions of wavelet-coefficients polarization maps of myocardium layers and death reasons.

Stokes polarimetry of the biological tissues laser imaging Fourier spectrum in the diagnosis of oncological changes

Taras Boychuk, Bukovinian State Medical Univ. (Ukraine); Mykola Raranskiy, Mikhailo Sakhnovskiy, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

This paper presents a data on the method of coordinate distributions determining of Stokes vector laser images parameters of biological tissue in the frequency Fourier plane. Courtesy description of the experimental setup - Fourier stokespolarimetr of biological tissues and fluids. The optical model of polycrystalline networks of histological sections of rectum wall is suggested. The results of investigating the interrelation between the values of statistical (statistical moments of the 1st-4th order) parameters are presented. They characterize the coordinate distributions of the fourth parameter of Stokes vector of Fourier transforms of laser images of rectum wall histological sections and oncological changes. The diagnostic criteria of rectum cancer are determined.

A complex noise reduction method for improving visualization of SD-OCT skin biomedical images

Oleg O. Myakinin, Ivan A. Bratchenko, Dmitry V. Kornilin, Valeriy P. Zakharov, Samara State Aerospace Univ. (Russian Federation); Alexander G. Khramov, Image Processing Systems Institute (Russian Federation)

In this paper we consider the original method of solving noise reduction problem for visualization's quality improvement of SD-OCT skin and tumors biomedical images. The principal advantages of OCT are high resolution and possibility of in vivo analysis. We propose a two-step algorithm: 1) process of raw one-dimensional A-scans of SD-OCT and 2) remove a noise from the resulting B(C)-scans. The general mathematical methods of SD-OCT are unstable: if the noise of the CCD is 1.6% of the dynamic range then result distortions are already 25-40% of the dynamic range. We use at the first stage a resampling of A-scans and simple linear filters to reduce the amount of data and remove the noise of the

CCD camera. The efficiency, improving productivity and conservation of the axial resolution when using this approach are showed. At the second stage we use an effective algorithms based on Discrete Wavelet Transform and Hilbert-Huang Transform for more accurately noise peaks removal. The effectiveness of the proposed approach for visualization of malignant and benign skin tumors (melanoma, BCC etc.) and a significant improvement of SNR level for different methods of noise reduction are showed. Also in this study we consider a modification of this method depending of a specific hardware and software features of used OCT setup. The basic version does not require any hardware modifications of existing equipment. The effectiveness of proposed method for 3D visualization of tissues can simplify medical diagnosis in oncology. Effective ways to implement a parallel version for high performance systems was considered.

An effective method of image registration for super-resolution

Yue Pang, Lingjia Gu, Ruizhi Ren, Jian Sun, Jilin Univ. (China)

Super-Resolution is an image enhancement technique that generates a high-resolution image from several low-resolution observations, whose goal is to increase the details of image, and thus we can obtain better visual effect. Super-Resolution is most commonly used in remote sensing, medical imaging, surveillance video and video standard conversion. During the imaging acquisition process, the sub-pixel shifts between the low-resolution images can produce non-redundant information. The basic idea behind Super-Resolution is to extract the non-redundant information from several low-resolution images and further combine them. According to the reconstruction-based method of Super-Resolution, the process of it mainly contains two parts including image registration and high-resolution image estimation. At present, many appropriate image registration and estimation methods exist in different situations and accurate estimation of both parts can benefit each other. However, some image registration methods are only accuracy for small-angle estimation, not for large-angle approximation. In addition, some high-resolution image estimation methods are easier to incorporate constraints and priors, but which have the disadvantages of heavy computation and slow convergence. Based on the current mainstream methods, an effective method of super-resolution imaging reconstruction is proposed in the paper. The proposed method is a better combination of present methods, which also takes into account the registration precision and the computation efficiency. The experimental results demonstrate that the proposed method is effective in the imaging reconstruction using the simulation and real test images.

Evaluation of different classifiers for palmprint based personal identification

Mustafa Mumtaz, Hassan Masood, Rafia Mumtaz, National Univ. of Science and Technology (Pakistan)

The ever increasing demand of security has resulted in wide use of Biometric systems. Palmprint based personal verification is an accepted biometric modality due to its reliability, ease of acquisition and user acceptance. This paper presents a novel palmprint based identification approach which draws on the textural information available on the palmprint by employing Non Sub Sampled Contourlet Transform. Center of the palm is calculated using the Distance Transform and by calculating the parameters for the best fitting ellipse, the alignment of hand θ is found. Rotational invariance is achieved by cropping a square region of size 256 x 256 pixels around the center aligned at θ degrees. After establishing the region of interest (ROI), the two dimensional (2-D) spectrums is divided into fine slices, using iterated directional filter banks. Next, directional energy components for each block of the ecomposed subband outputs are computed. The proposed algorithm captures global details in a palmprint as fixed length palm codes. Palmprint matching is then performed using Normalized Euclidean Distance Classifier, Support Vector Machine and Baysian Classifier. Subject methods are tested on a total of 500 palm images of GPDS Hand database, acquired from University of Las Palmas de Gran Canaria, Spain. The experimental results were compiled for individual classifiers. The use of different classifiers demonstrated their strength and feasibility in application to palmprint biometric modality. The results from Support Vector Machine shows the best results by exhibiting Genuine Acceptance rate of 99.2%, Decidability Index of 2.7782 and Equal Error rate of 0.4133%.

A novel method for detection of preferred retinal locus (PRL) through simple image processing using MATLAB

Venkataramana Kalikivayi, Sudip Pal, Angarai R. Ganesan, Indian Institute of Technology Madras (India)

Although there are various methods like micro perimeter, Scanning Laser Ophthalmoscope (SLO) available in detecting 'Preferred Retinal Locus' (PRL), a simple and new technique has been proposed in this paper. The technique uses simple MATLAB algorithms in detecting the RGB color pixel intensity values of normal retinal images and images with central scotomas. This technique proved non-existence of 'S' cones in Fovea Centralis and also proposes rods are involved in blue color perception. Similarly, the average photoreceptor cells ratio has also been studied. Retinal images of central vision loss and normal retina were taken for image processing. Blue minimum, Red maximum and Red+Green maximum were the three methods used in detecting PRL. All three methods spotted the same location of the PRL. Comparative analyses were also performed for these methods with patient's visual acuity and visual fields. Preliminary studies show promising results for the proposed method in terms of reliability and repeatability.

Real-time 3D imaging by using color structured light based on Hilbert transform

Jiping Guo, Shenzhen Univ. (China) and Shenzhen Academy of Metrology and Quality Inspection (China); Xiang Peng, Shenzhen Univ. (China); Jiping Yu, Shenzhen Academy of Metrology and Quality Inspection (China); Ameng Li, Yongkai Yin, Meng Wang, Shenzhen Univ. (China)

A method for real-time three-dimensional (3D) reconstruction based on Hilbert transform is proposed. Based on the properties of Hilbert transform and De Bruijn sequence, we design an encoding technique based on color fringe patterns to realize 3D reconstruction of the phase distribution and range images. The calculation of phase map is implemented by using two sinusoidal fringe patterns with phase shifting 0 and pi/2 each other. Two phase-shifted fringe patterns are assigned to the red and blue channel of a color pattern, respectively. After color calibration of the captured color pattern picture having been done, the phase unwrapping is accomplished with aid of the De Bruijn sequence pattern stored in the green channel. With the parameters of a pre-calibrated 3D imaging system consisting of a cameral and a projector, we can calculate the 3D range data of the object. A spoon has been measured by this method. The experiment results show that the proposed method can not only acquire 3D data in real-time and one-shot fashion, but also obtain high-resolution and high-density range image data without any error propagations.

Image reconstruction in speckle interferometry

Yuanyuan Ding, Shanghai Astronomical Observatory (China)

Speckle imaging technique is one of the several effective methods, which can overcome atmosphere turbulence effects and obtain diffraction-limited resolution of objects. It is achieved by the integration of a series of short-exposure images of the object.

This paper is the part of a series dedicated to the speckle imaging of binary stars carried out by the research team of Shanghai Astronomical Observatory. The observation experiments were carried out from 2010 to 2012 with 1.56-m telescope using a speckle camera, and the high resolution image were reconstructed successfully.

In this paper, we mainly concerned speckle interferometry and iterative shift-and-add. Speckle interferometry was proposed by Labeyrie in 1970, the information obtained in this manner is not easily interpreted because the final output after processing is the autocorrelation of the object. This technique has been widely used in the observational astronomy, especially in binary stars. Iterative Shift-and-Add is working in spatial domain, the complex Fourier phase recover is avoided in this method and the data processing become much easier.

As we know, speckle imaging algorithm needs to deal thousands of images, and the high computational complexity brings a lot of problems. Modern GPUs are very efficient at manipulating computer graphics, and their highly parallel structure makes them more effective than general-purpose CPUs for algorithms where processing of large blocks of data is done in parallel. So we proposed a reconstruction software based on CUDA architecture, compared with C++ program based on CPU, the speed ratio can reach 10 times.

Modeling of quantization noise in linear analog-to-digital converter

Jan Švihlík, Institute of Chemical Technology (Czech Republic); Karel Fliegel, Czech Technical Univ. in Prague (Czech Republic)

Quantization noise is present in all the current digital imaging systems, therefore its understanding and modeling is crucial for optimization of image reconstruction techniques. Hence, this paper deals with modeling of the quantization noise. We exploit the undecimated wavelet transform (UDWT) for signal representation. We assume that the quantization noise in the spatial domain can be seen as additive, white and uniformly distributed. Hence, the UDWT causes the transform of noise distribution due to weighted sum of noise samples and filter coefficients. From the known quantization step we are able to estimate suitable moments of noise uniform probability density function (PDF). These moments then could be directly evaluated in the undecimated wavelet domain using the derived equations. The presented algorithm gives the a priori information about the quantization noise and can be used for the suppression of it.

A comparison between x-lets in denoising cDNA microarray images

Hossein Rabbani, Isfahan Univ. of Medical Sciences (Iran, Islamic Republic of)

Microarray technology has become a power tool in the field of bioinformatics. It is used to measure gene expression levels which similar to any other image capturing processes is prone to noise. There are different kind of noise, during preparation, hybridization and scanning in microarray images. In the literature, the noise is usually modeled by a Gaussian and Poisson probability density function (pdf), but the Poisson noise can also be converted to Gaussian noise, therefore only effect of Gaussian noise is studied. Since introduction of wavelets in 1970s, many more forms of this transform have been developed and used, such as stationary wavelet transform (SWT), complex wavelet transform (CWT), curvelet transform (CURV), contourlet transform (CNT), etc. By developing of more sparse transforms, it is important to have a perspective of how efficient the transforms are in different applications, such as microarray technology. In this paper, we compare the efficiency of common sparse transforms including discrete wavelet transform (DWT), SWT, CWT, CURV, CNT, contourlet-SD decomposition, steerable pyramid (SHR) and shearlet transform (ST) using different quality indexes like peak signal-to-noise ratio (PSNR), structural similarity (SSIM) index, and edge preservation index (EPI). For this reason after converting microarray image into x-let transform, BayesShrink method and soft thresholding is used to perform denoising of these images. Both local and general thresholds are calculated for each subband in order to evaluate the effect of incorporating intrascale dependency on top of sparsity property in statistical modeling of x-let's coefficients. Our simulation results show that CWT and SHR outperforms the others. Although SHR has better performance for some criteria like SSIM, but CWT is faster than SHR. We are now working to develop a new transform namely circlelet which has been designed based on this fact that the main objects in microarray images are circle-like objects.

Development of FORMOSAT-5 automatic cloud coverage assessment method

Kuo-Hsien Hsu, National Space Organization (Taiwan)

FORMOSAT-5 is the fourth satellite owned by National Space Organization (NSPO), National Applied Research Laboratory (NARL) of Taiwan. The primary payload of FORMOSAT-5 is a high-spatial-resolution (2meters) optical Remote Sensing Instrument (RSI). FORMOSAT-5 is currently scheduled to be launched in 2014. Specifically, FORMOSAT-5 imagery is a kind of remote sensing satellite data, which includes one panchromatic band and four multispectral bands (Blue, Green, Red, near-infrared). An essential sector in the daily processing of received FORMOSAT-5 imagery is to estimate the cloud statistic of imagery by using Automatic Cloud Coverage Assessment (ACCA) method. The information of cloud statistic of imagery is subsequently recorded as an important metadata for corresponding imagery product catalog. In this paper, our proposed ACCA method is generally divided into two consecutive stages: pre-processing and post-processing analysis for the cloud statistic estimation and results examination, respectively. For pre-processing analysis, the un-supervised K-means classification, edge-detection method, thresholding method, and non-cloudy pixels reexamination are implemented in sequence. A simulated FORMOSAT-5 imagery with a broad range of different kind of scene features is used for validation. The research supports that the use of our proposed ACCA method as a reliable approach for the cloud statistic estimation of the FORMOSAT-5 imagery.

Polarization mapping temporal changes of the eye optical anisotropy laser images necrotic changes in the diagnosis of biological tissues

Taras Boychuk, Darina Popovych, Bukovinian State Medical Univ. (Ukraine)

This research is focused on the study of potentiality of laser mapping of polarization azimuths and ellipticity distribution of eye vitreous body laser images with the aim to define the prescription of death coming.

The research was carried out at the conventional setup of laser polarimeter. By turning the analyzer axis at an angle within 00 – 1800 the arrays of minimal and maximal intensity levels of biological tissue image were determined for every pixel of CCD-camera, as well as the rotation angles corresponding to them. Further, the coordinate distributions (polarization maps) of polarization azimuths of a biological object were calculated.

The statistic structure of coordinate distributions of ellipticities of an image of biological tissue histological section is most objectively characterized by the ensemble of statistical moments 1st – 4th orders. As objects of investigation the histological sections of human eye vitreous body tissue were used, taken in 4 hours and 72 hours after death coming.

The dynamics of change of random distribution of polarization ellipticity is characterized by the following difference between the values of statistical moments of the 1st -4th orders: mean ; dispersion – ; asymmetry – ; excess – . It is obvious that the values of all statistical moments, as well as those of polarization azimuth distributions, change manifold within one order of a value with the increase of time after death coming.

The statistical moments of 3rd -4th orders of values distributions of polarization azimuths and ellipticity of the laser object field of human eye vitreous body tissue appeared to be the most informative.

Fourier analysis of blood plasma laser images phase maps in the diagnosis of cancer in human organs

Taras Boychuk, Bukovinian State Medical Univ. (Ukraine); Alexander Ushenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Ozar Mincer, Bukovinian State Medical Univ. (Ukraine); Lidiya Kushnerick, Pavlo Angelsky, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Natalia Bodnar, Bukovinian State Medical Univ. (Ukraine); Boris Oleinichenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

The main idea of such an approach lies in the fact that spatial-frequency structure of the Fourier form of the laser image of the polycrystalline network of blood plasma is different for its large scale albumin and small scale protein structures. Therefore, through space-frequency filtering one can mainly select either low-frequency (with linear birefringence) or high-frequency (with circular birefringence) components which by means of reverse Fourier transformation can be converted into corresponding “separated” laser images.

A model of the polycrystalline networks optical anisotropy of blood plasma has been suggested and the method of Fourier phasometry of linear parameters (a phase shift between the orthogonal components of the laser wave amplitude) and circular (the angle of rotation of the polarization plane) birefringence with a spatial-frequency selection of the coordinate distributions for the differentiation of acute and gangrenous conditions have been analytically substantiated.

Comparative studies of the efficacy of the methods of direct mapping of phase distributions and Fourier’s phasometry of a laser radiation field transformed by the dendritic and spherulitic networks of albumin and globulin of the layers of breast and colon effusion on the basis of statistical analysis of the structure of phase maps.

A set of criteria of a polarization-phase differentiation of normal and cancer states has been detected and substantiated: statistical moments of the 1st - 4th order, which characterize the distribution plane relations of polarization laser radiation stipulated by circular birefringence of blood plasma network.

2D reconstruction of biological tissues polycrystalline structure by analyzing Mueller-matrix singular images

Taras Boychuk, Bukovinian State Medical Univ. (Ukraine); Liliya Trifonyuk, Rivne Oncological Regional Hospital (Ukraine); Vitaliy Balazyuk, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

In this work, we have theoretically grounded conceptions of characteristics points observed in coordinate distributions of Mueller matrix elements for a network of human tissue biological crystals. Found is interrelation between polarization singularities of laser images inherent to these biological crystals and characteristic values of above matrix elements.

As objects for our experimental investigations, we used mounts of myometrium tissue of two types:

• biopsy of healthy tissue from a woman matrix (type A);

• biopsy of conditionally normal tissue from the vicinity of a benign hysteromyoma (type B).

We have determined criteria for statistical diagnostics of pathological changes in the birefringent structure of biological crystal network by using myometrium tissue as an example.

- values of the skewness coefficient for distributions of Mueller matrix images (MMI) characteristic values describing the pathologically changed myometrium tissue of B type grow practically by one order, which indicates formation of their azimuthal asymmetry related with the direction of pathological growth of birefringent protein fibrils.

Thus, the above analysis of statistical distributions describing the number of points for MMI characteristic values inherent to the set of matrix elements characterizing biological tissues of different kinds seems to be efficient in differentiation of phase and orientation changes in the structure of their birefringent components, which are related with changes in their physiological state.

Singular structure of Mueller matrices images of biological crystal networks for diagnostic human tissues pathological changes

Volodimir G. Ushenko, Mikhailo Sakhnovskiy, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

The interconnection between geometry of organic crystal structure with their polarization properties has been studied. It has been shown that for physiologically normal biological tissues polarization properties of radiation scattered on architectonic nets formed by protein fibrils possess the fractal character. Pathological changes of organic crystal architectonics are accompanied with the transformation of singular structure of Mueller-matrix images.

It has been demonstrated that self-similar geometric structure of architectonic nets of physiologically normal organic crystal of various morphology manifests itself in the singular character of their polarization properties, described by the totality of 2D elements of Mueller matrices. The processes of pathological changes of organic crystal architectonics manifest themselves in the appearance of new inclinations and the transformation of the structure of Mueller – matrixes images orientation elements into a stochastic one and by the transformation of large-scale structure of Mueller – matrixes images phase elements into a statistic one. Degenerative-dystrophic changes manifest themselves in randomization of coordinate distributions of Mueller matrices of orientation elements of large-scale architectonics elements and by complete destruction of self-similar structure of Mueller – matrixes images of phase elements.

8856-84, Session PWed

Correlation and self similarity structure of polycrystalline network biological layers Mueller matrices images

Volodimir G. Ushenko, Alexander V. Dubolazov, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

The application of lasers in biomedical diagnostics gave the possibility to use the polarization analysis of different kind object fields – speckle-modulled fields, the transformation operator of which is Mueller matrix. The topological inhomogeneity of coherent fields makes it possible to get the information on such an operator's microstructure, which is inaccessible for the traditional nephelometry and is defined by the object morphology specificity.

This investigation is aimed at studying Mueller matrix microstructure of architectonics of different morphological structure organic crystals; at searching the correlation of orientation, anisotropy parameters of multifractal nets with the topological distribution of matrix elements and their indices.

The interrelation of orientation, anisotropy structure of organic crystals architectonics and topological element distribution of Mueller's matrices is investigated here. It is researched the analytical correlation of object Mueller's matrices microstructure with matrix element indices measured in the far field of Fraunhofer's diffraction. The investigation is also dealt with the computer modeling and experimental researching the structure of matrix operator of multifractal amorphous – crystalline organization of different morphological structure biotissues.

Here it has been studied the correlation Mueller's matrices microstructure of biotissues and determined the interrelation of orientation, anisotropy structure of multifractal nets of their architectonics as systems of optically uniaxial crystals with the topological distribution of matrix elements within object plane.

Mueller-matrices polarization selection of two-dimensional linear and circular birefringence images

Volodimir G. Ushenko, Galina Koval, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

The polarimetric method of information polarization selection, which is effective in phase-inhomogeneous layer (PIL) diagnostics in their images has been presented. The possibilities of polarization-correlation analyses of architectonics images of the BT have been studied.

The 2-component amorphous-anisotropic model of describing optical properties of boitissues of different morphological structure was analyzed.

Based on 2-component amorphous-anisotropic model of describing optical properties of boitissues of different morphological structure the correlation structure of the images of biostructures with various types of architectonics were experimentally investigated:

texture-ordered (butterfly's wing, scale);

biotissues with fibrillar type of architectonics (bone and myocardium tissue);

biotissues with disordered architectonics (lymph and large intestine).

It was shown that geometric structure of all types of investigated bioobjects possesses either fractal or stochastic character. Observations of optical anisotropy of such objects architectonics are individual for each of them.

It was determined that inflammation processes lead to statistic character of the optica0anisotropic images structure. Degenerative-dystrophic changes are shown in destroying fractal structure of images of large-scale architectonic elements.

Experimental evaluation of vergence-accommodation conflict for various stereoscopic display technologies and stereoscopic content

Tomas Jindra, Karel Fliegel, Stanislav Vitek, Milos Klima, Czech Technical Univ. in Prague (Czech Republic)

Conventional 3D stereoscopic and autostereoscopic displays suffer from conflict between vergence and accommodation. The vergence-accommodation mismatch is one of important factors potentially causing visual discomfort to viewers of stereoscopic presentations. This paper presents a study analyzing the vergence-accommodation mismatch for a group of observers based on simultaneous measurement of vergence and accommodation. Our own video based eye-tracking system was coupled with stereoscopic or autostereoscopic display while various types of stereoscopic content were presented to the viewers, including real-world and artificial stimuli. Quality of presented stereoscopic images is subjectively assessed by the observers and the subjective results are consequently compared with the measured vergence and accommodation parameters. Correlation analysis between the subjective scores and measured viewing parameters is presented. This analysis aims to answer the question on how the vergence-accommodation conflict affects quality of viewing experience for stereoscopic and autostereoscopic displays with various types of stereoscopic content. The experiment extends our previously published results where only simple stereoscopic stimuli were utilized including also natural stereoscopic content.

Skin chromphore mapping by means of a modified video-microscope for skin malformation diagnosis

Amina Bekina, Uldis Rubins, Ilze Diebele, Janis Zaharans, Janis Spigulis, Univ. of Latvia (Latvia)

In this study digital video-microscope was modified for an advanced skin surface monitoring. The skin lesions were illuminated with four-color LED system – red (660 nm), green (545 nm), blue (450 nm) and infrared (940 nm). A set of four images has been obtained at each measurement. Specific values related to the R-, G- and B- bands at each pixel are selectively extracted from the image and used for multispectral analysis of the image. Additionally spectral images were calibrated with white reference (I_ref) to prevent overexposition of the skin malformation image. Spectral image intensity (I_skin) was calculated using the following formula: OD=log ((I_ref-I_noise)/I_skin-I_noise). From these stabilized images three chromophore maps are calculated: hemoglobin, erythema and melanin. Hemoglobin map can be found from the relation between two spectral images at red and green illumination. Erythema index is calculated by the deviation of two residuals: E=(I_green-I_red)/ (I_blue-I_red). Melanoma related map can be found from following formula: M=I_green/I_red/I_infrared . Wavelength 545 nm (green) corresponds to maximum absorption of blood, while at 650 nm (red) hemoglobin absorption is minimal and melanin absorption is more pronounced, and 940 nm (infrared) is the longest available wavelength corresponding to the deepest penetration under the skin surface. There are visible differences between the chromophore maps. The hemoglobin map more highlight the intradermal structures of skin while the melanin map highlight the upper pigmented tissue layers.

Graphical user interface (GUIDE) and semi-automatic system for the acquisition of anaglyphs

Marco A. Canchola Chávez, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Juan A. Arízaga Silva, Jose M. Cantero Nava, Eduardo Tepanecalt Castillo, Univ. Tecnológica de Puebla (Mexico)

Several studies in the area of pedagogy have shown greater acceptance by youth to ideas related to science, using various teaching techniques or experiments, compared to just the texts in the classroom. That fact and showing great curiosity, are factors to consider to undertake scientific outreach efforts for children, with prospects of success.

Moreover now 3D digital images have become a topic that has gained importance in various areas, entertainment, film and video games mainly, but also in areas such as teaching transcendental.

This paper presents a system model for 3D images for education that allows students of various grade levels, school and college, have an approach to image processing, explaining the use of filters for stereoscopic images that give brain impression of depth.

The system is based on one of two hardware elements, centered on an Arduino board, and a software based on Matlab. The paper presents the design and construction of each of the elements, also presents information on the images obtained and finally how users can interact with the device.

Real time soft-partition-based weighted sum filtering using GPU implementation

Shuqun Zhang, College of Staten Island (United States)

Recently image processing such as restoration, super-resolution and noise reduction using soft-partition based weighted sum filters have shown state-of-the-art results. Partition-based weighted sum filters are spatially adaptive filtering techniques by combining vector quantization and linear finite impulse response filtering concepts, which have shown to achieve much better results than spatial-invariant filtering methods. However, they are computationally prohibitive for practical applications because of enormous computation involved in both filtering and training. Real-time processing is impossible even for small window size. In this paper present a fast implementation of soft-partition based weighted sum filters by exploiting the massively parallel processing capabilities of a GPU within a CUDA framework owing to its easy off-the-shelf availability and programmer friendliness. To our knowledge there is no GPU implementation reported for partition based weighted sum filters yet. For the implementation, we focus on memory management, system design, and implementation strategies. The performance on various window sizes is measured and compared between GPU-based and CPU-based implementations. The results indicate that GPU-based implementation can significantly accelerate computations for filtering and training, and make real-time filtering become possible. Application in image restoration is also demonstrated.

Analysis of skin moles from optical spectropolarimetric images

Yitzhak Yitzhaky, Lior Graham, Ibrahim Abdulhalim, Ben-Gurion Univ. of the Negev (Israel)

Imaging of the skin to detect the signs of cancer becomes very common these days. A new noninvasive skin imaging method developed recently gives an informative image data about the skin tissue by collecting scattered polarized light reflected from a mole area. This method, called Differential Optical Spectropolarimetric Imaging (DOSI), scans the polarization states by continuously rotating a linearly polarized light incident on the lesion and collecting the reflected sequence of images with a CCD camera. The two main wavelengths that were used in the study were 520nm (penetration is about 100µm) and 700nm (penetration is about 200µm). The recorded images were taken from ten patients who came to remove various skin lesions in the Ambulatory Surgery Department of Plastic Surgery in Soroka-Hospital.

Methods developed in the past to diagnose suspicious moles were implemented to visual images. However, such methods cannot be employed directly to the DOSI images because of their different properties. For example, unlike visual images, DOSI images do not have color information. In this paper, we propose a novel method to distinguish cancerous from healthy moles by analyzing the images obtained by this new imaging system. The proposed method first pre-processes the image of the mole, which include image de-noising, intensity-based segmentation of the mole region and contour formation of the segmented regions. Then, it performs an automatic examination of the polarized images according to characteristics such as their border disorder, asymmetry, cross-image local contrasts and large-scale homogeneity. Results show good separation between cancerous and healthy moles.

Autofocusing in microscopy systems using parallel computing

Jorge Alberto Hernández Tapia, Juan Carlos Valdiviezo-Navarro, Carina Toxqui Quitl, Alfonso Padilla-Vivanco, Univ. Politécnica de Tulancingo (Mexico)

Autofocusing is of fundamental importance for a real time automatic system. In particular, for microscopy applications, a desired automatic system should provide the best focused image with enough accuracy and the minimum computational time. During the last years several metrics based on images have been proposed to achieve the autofocusing process. Although many of these techniques present good accuracy in microscopy applications, their main limitations reside in the high computational time required to find the best focused image. Moreover, in recent years the development of graphical processing units (GPUs) has given place to new and diverse applications oriented to diminish the computational effort associated to the central processing unit (CPU). This manuscript presents an implementation of different autofocusing techniques, such as Vollath F4, Tenengrand, Mid-Frequency Discrete Cosine Transform, and Spatial Frequency, using tools of parallel computing. The main objective of the proposed manuscript is to show that by using a GPU is possible to speed up the computational time required to perform the above mentioned techniques. Preliminary results obtained when applying parallel computing to a stack of microscopy images have allowed us to reduce the computational effort around 12%. Hence, parallel computing can be effectively used for autofocusing in real time microscopy applications.

Automatic fuzzy based level set method for segmentation of Barrett's esophagus in endoscopy images

Hossein Yousofi, Hossein Rabbani, Peyman Adibi, Isfahan Univ. of Medical Sciences (Iran, Islamic Republic of)

Evaluation of the Barrett's disease progress needs to detect the baseline; a region in endoscopy images that esophagus tissue is finished and stomach tissue started. The main purpose of this paper is segmentation of Barrett's esophagus in endoscopy images automatically using a fuzzy based level set method. Both fuzzy C-means (FCM) and level set methods fail to segment this type of medical image due to weak boundaries. This paper tries to benefit from the advantages

of both methods for segmentation of Barrett's esophagus. In image segmentation by nave level set method, contour initialization needs manual manipulation. A modified fuzzy based level set method is proposed in this paper to segment Barrett's esophagus automatically. We use FCM algorithm with spatial information to cluster image into number of clusters. By computing the correlation between obtained fuzzy clusters and a binary of original image with a proper threshold, we can define the best initial contour to serve the level set algorithm. The final segmentation is obtained from level set method that uses the sign pressure force function for controlling the contour. Results showed that this proposed method can segment Barrett's esophagus in endoscopy images effectively.

The best features selection for Leukocytes classification in blood smear microscopic images

Omid Sarrafzadeh, Hossein Rabbani, Ardeshir Talebi, Isfahan Univ. of Medical Sciences (Iran, Islamic Republic of)

Automatic differential counting of leukocytes provides invaluable information to pathologist for diagnosis and treatment of many diseases. The main objective of this paper is to detect leukocytes from a blood smear microscopic image and classify them into their types: Neutrophil, Eosinophil, Basophil, Lymphocyte and Monocyte using features that pathologists consider to differentiate leukocytes. Features include color, geometric and texture features. Colors of nucleus and cytoplasm vary among the leukocytes. Lymphocytes have single, large, round or oval and Monocytes have singular convoluted shape nucleus. Nucleus of Eosinophils is divided into 2 and of Neutrophils into 2 to 5 segments. Lymphocytes often have no granules, Monocytes have tiny granules, Neutrophils have fine granules and Eosinophils have large granules in cytoplasm. We extract 6 color features from both nucleus and cytoplasm, 6 geometric features only from nucleus and 6 statistical features and 7 moment invariants features only from cytoplasm of leukocytes. The features are fed to support vector machine (SVM) classifiers with one to one architecture. The results obtained from applying the proposed method on blood smear microscopic images of 10 patients including 149 white blood cells (WBCs) indicate that correct rate for all classifiers are above 93% which is in a high level in comparison with previous literatures.

8856-95, Session PWed

Comparison of macular OCTs in right and left eyes of normal people

Tahereh Mahmudi, Raheleh Kafieh, Hossein Rabbani, Isfahan Univ. of Medical Sciences (Iran, Islamic Republic of)

Optical coherence tomography (OCT) is a non-invasive imaging modality being used in the diagnosis and management of a variety of ocular diseases including glaucoma, age-related macular degeneration (AMD) and diabetic macular edema. It is a powerful modality to qualitatively assess retinal features and pathologies or to make quantitative measurements of retinal morphology. Retinal 3D OCT volumes are commonly used for clinical diagnosis or investigation. But accurate and fast analysis of large volumes of data is difficult for clinicians. Therefore, automatic extraction of useful information from OCT images, such as calculating total retinal thickness and nerve fiber layer (NFL) thickness (RNFLT) have become increasingly significant. It is also important to have information about thickness of retinal layers in right and left eyes. If the asymmetry of RNFLT in normal eyes is not taken into consideration, a mistake could be made in evaluating whether there is damage or not. The only published study in this area by park et al. suggested that the RNFLT around Optic Nerve Head in normal eyes is not symmetrical within individual eyes nor symmetrical between the right and left eye. In this study we investigate the thickness values in two eyes in an area around the macula. Retinal borders and RNFL border were segmented by diffusion map method and thickness profiles were made. To show the result, RNFLT and retinal thickness were analyzed by dividing three circle scanning areas (diameter 1, 3, 6 mm) around the macula into 4 quadrants and 9 sectors.

Automatic diagnosis of malaria by use of least square circle-ellipse fitting search

Monireh Sheikhhosseini, Isfahan Univ. of Technology (Iran, Islamic Republic of); Hossein Rabbani, Isfahan Univ. of Medical Sciences (Iran, Islamic Republic of); Maryam Zekri, Isfahan Univ. of Medical Sciences (Iran, Islamic Republic of) and Isfahan Univ. of Technology (Iran, Islamic Republic of); Ardeshir Talebi, Isfahan Univ. of Medical Sciences (Iran, Islamic Republic of)

Diagnosis of malaria parasitemia from blood smears needs enormous time and effort. Automatic diagnosis process is able to reduce the diagnosis time, also it may be useful in malaria screening. This study presents an automatic method for diagnosis malaria in thin blood smears. First step of malaria diagnosis is identifying stain objects which are colored through staining process. Infected cells are verified by applying complete searching process on smooth image which makes use of nonlinear diffusion filtering. Searching procedure is composed of circle search, least square ellipse fitting and ellipse search sections. Circle search process determines the direction and initial points for ellipse fitting algorithm, while ellipse search process completes the shape of parasite. Also, far points with high error value from fitted ellipse are removed and final ellipse parameters are modified by applying ellipse search algorithm. The method was applied on total 418 Red Blood Cells (RBCs) and our experiments show high sensitivity and specificity which are 94.74% and 97.11% respectively.

Study of 3D solder-paste profilometer by dual digital fringe projection

Yi-Hua Juan, Jeng-Nan Yih, National Kaohsiung Univ. of Applied Sciences (Taiwan)

In a 3D profilometer by the fringe projection, the shadow will be produced inevitably, thus the fringes cannot be detected in the region of the shadow. In addition, a smooth surface or a metal surface produces the specular reflection, and then, no projection fringe can be recorded in the region of oversaturation on CCD. This paper reveals a proposed system for improved these defects and shows some preliminary improved 3D profiles by the proposed dual fringe projection.

To obtain the profile of sample hided in the shadow and the oversaturation, this study used the dual-projection system by two projectors. This system adopted two different directions of fringe projection and illuminates them alternately, therefore, the shadow and the oversaturation produced in their corresponding locations. Two raw 3D profiles obtained from taking the dual-projection by the four-step phase-shift. A set of algorithms used to identify the pixels of the shadow and the oversaturation, and create an error-map. According to the error-map to compensate, two 3D profiles merged into an error-reduced 3D profile. We used the solder paste as a testing sample. After comparatively analyzing the 3D images obtained by our measurement system and by a contact stylus profilometer, the result shows that our measurement system can effectively reduce the error caused by shadows and oversaturation.

Scene-based non-uniformity correction algorithm for continuous monotonous scene motion based on FPGA

Honglie Xu, Qian Chen, Ning Liu, Chunhua Yang, Nanjing Univ. of Science and Technology (China)

In this paper, we focus on the real scope of application and the non-uniformity appearance of the IR imager and propose a new scene-based non-uniformity correction technology. We consider the inadequacies of other non-uniformity correction algorithms and find out that most of them are only used in lab. The scene set for these algorithms often fits themselves in most cases. In real application, the scene is mostly towards one monotonous direction and has different appearance of non-uniformity. We solve these problems by developing a new projection estimator for the registration with a criterion, and realize this technology on a hardware system. This system is fully engineered for some particular usage. We test the performance of our technology by the evaluation indexes, and demonstrate the actual effect of correcting the non-uniformity under a monotonous motion on the system. At the end of this paper, we make a conclusion and perspective of our research work.

Remote sensing of liquid level measurement using Fiber Bragg grating sensor

Dipankar Sengupta, M. Sai Shankar, Vidya Jyothi Institute of Technology (India); Kamineni Srimannarayana, Pachava Vengal Rao, National Institute of Technology, Warangal (India)

The present work proposes a simple low cost sensor head design making use of FBG sensor, for the remote sensing of liquid level measurement. The sensor head consists of a lever, a buoyancy tube and an FBG. The lever is used to transfer the buoyancy force due to change in liquid level to the FBG resulting in shift in Bragg wavelength. The Flexibility of this design enables to measure the liquid level in an open or closed tank.

A class I lever of length 50mm with equal arms is used. A buoyancy tube is fixed at one end of the lever. To the other end of the lever, an FBG of 3mm length is glued. The other end of the FBG is attached to the collar of the sensor arrangement with an adjusting screw for fixing the initial lever position and to give a minimal strain to the FBG and also to avoid its bending.

The sensor head is attached to a tank. To vary the liquid level in the tank, an inlet and outlet arrangement with a suitable controller is made. As the liquid level increases, an upward force acts on the buoyancy tube resulting in transfer of this force to the FBG, fixed between the collar and the lever end.

A broadband light source, a circulator and OSA are used for illuminating and recording the spectrum. During the experiment the temperature of the liquid is maintained constant. The prototype sensor head is tested by varying the liquid level in steps of one centimeter over a total span of 13 cm, the spectral shift of the Bragg wavelength was recorded. A linear change in Bragg wavelength with level is noticed with a sensitivity of 10.7pm/mm which shows the high sensitivity of the sensor head design.

A simple low cost interrogation system was made from splicing a suitable length of a 100/140?m fiber in between two single mode optical fiber (9/125 μm) which acts a linear edge filter in included in the experimental setup. As the shift in Bragg wavelength occur the intensity of the Bragg wavelength changes linearly as a result a low cost photo detector is high enough to detect the shift in wavelength.

8856-54, Session 8

Multiview wavelet transform for digital holography coding

Ângelo Arrifano, Univ. da Beira Interior (Portugal) and Univ. de Nice Sophia Antipolis (France); Marc Antonini, Univ. de Nice Sophia Antipolis (France); Manuela Pereira, Univ. da Beira Interior (Portugal)

In this paper we present multiview analysis of digital holograms by using the wavelet transform. We were successful on the reconstruction of stereoscopic information from a single phase-shift hologram captured using a 2.2μm pixel-pitch CMOS camera in a holographic interferometer configuration. The low pixel-pitch camera allows the digitizing of holograms with a higher spatial-frequency than what has been reported in the literature, allowing the recording of macroscopic objects closer to the camera sensor.

The reconstructed information can be visualized using 3D stereo glasses. From the perceived 3D we could identify several depth cues, including the occlusion effect which has not been easy to produce from single-aperture holography. The occlusion effect is also known to be difficult to produce from stereoscopic sources.

8856-55, Session 8

Using self-similarity compensation for improving inter-layer prediction in scalable 3D holoscopic video coding

Caroline Conti, Paulo Nunes, Luís Ducla Soares, Instituto de Telecomunicações (Portugal)

Holoscopic imaging, also known as integral imaging, has been recently attracting the attention of the research community, as a promising glassless 3D technology due to its ability to create a more realistic depth illusion than the current stereoscopic or multiview solutions. However, in order to gradually introduce this technology into the consumer market and to efficiently deliver 3D holoscopic content to end-users, backward compatibility with legacy displays is essential. Consequently, to enable 3D holoscopic content to be delivered and presented on legacy displays, a display scalable 3D holoscopic coding approach is required.

Hence, this paper presents a display scalable architecture for 3D holoscopic video coding with a three-layer approach, where each layer represents a different level of display scalability: Layer 0 - a single 2D view; Layer 1 - 3D stereo or multiview; and Layer 2 - the full 3D holoscopic content. In this context, a prediction method is proposed combining inter-layer prediction, aiming to exploit the existing redundancy between the multiview and the 3D holoscopic layers, and self-similarity compensated prediction (previously proposed by the authors for non-scalable 3D holoscopic video coding), aiming to exploit the spatial redundancy inherent to the 3D holoscopic enhancement layer.

Preliminary results strongly indicate that the proposed prediction method can improve significantly the rate-distortion performance of scalable 3D holoscopic video coding with respect to the authors' previous proposed solution, where only inter-layer prediction is used.

Compression of computer generated phase-shifting hologram sequences

Yafei Xing, Béatrice Pesquet-Popescu, Frederic Dufaux, Telecom ParisTech (France)

In this paper, an algorithm for compressing the computer generated phase-shifting hologram (CGPSH) sequences is presented to reduce the storage burden of digital holograms. By simulating phase-shifting digital holography (PSDH) interferometry, interference patterns between illuminated three dimensional(3D) virtual objects and the stepwise phase changed reference wave are generated as holograms in computer. The hologram sequences obtained by the movement of the virtual objects are compressed by a coding technique, e.g.,H.264/AVC, and a new representation method using the movement information of the objects are applied, respectively, the effectivenesses are compared as well.

PEViD: privacy evaluation video dataset

Pavel Korshunov, Touradj Ebrahimi, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Visual privacy protection, i.e., obfuscation of personal visual information in video surveillance is an important and increasingly popular topic. However, while many datasets are available for testing performance of various video analytics, little to nothing exists for evaluation of visual privacy tools.

Since surveillance and privacy protection have contradictory objectives, the design principles of corresponding evaluation datasets should differ too. In this paper, we outline principles that need to be considered when building a dataset for privacy evaluation and present a new, and the first to our knowledge, public privacy evaluation video dataset (PEViD). This dataset can be used to evaluate a variety of privacy protection tools by either objective metrics or subjective tests.

Conference 8857: Signal and Data Processing of Small Targets 2013

8857-1, Session 1

Object detection via fast discrete Curvelet transform

Hector Valdez, California State Univ. (United States); Thomas T. Lu, Tien-Hsin Chao, Jet Propulsion Lab. (United States)

Object detection is of great interest in the field of intelligent computer vision. The premise of intelligent computer vision is the hope of one day mimicking the full capability of the human visual pathway. This paper describes an automated object detection framework that is capable of processing images quickly with the primary goal of tracking objects of interest over time. We accomplish this task by means of the Fast Discrete Curvelet Transform (FDCT), which is relatively new in the subject of harmonic analysis. The distinguishing difference between FDCT and other transforms is that the curvelet coefficients have three beneficial parameters which define scale, orientation, and spatial locations. We utilize these parameters to our advantage in order to efficiently detect relatively small objects in a variety of image/video data sets. We have implemented the FDCT in the first stage of target detection in a multi-stage automated target recognition architecture. The results of the current algorithm yield a highly sensitive detection of small targets in noisy background. We will give a brief analysis of the curvelet transform, discuss the framework of the FDCT object detection stage and analyze the experimental results.

8857-2, Session 1

Iteratively compensating for multiple scattering in SAR imaging

Alejandro F. Martinez, Zhijun G. Qiao, The Univ. of Texas-Pan American (United States)

The Born approximation is a common approximation taken in modeling the physics of SAR imaging. In essence it says that radiation only scatters once when in space. This is a reasonable assumption for targets that lie far apart or that are far from the transmit and receive antennas, but it introduces error into the imaging process.

The goal of this paper is to iteratively compensate for this error in the model by using estimates of the target distribution to estimate multiple scattering phenomena. We will use a wavelet based noise reduction technique at each iteration on the corrected data as well as the estimated image to control any excess error introduced by the estimated multiple scattering phenomena. The physical model for our work will be based on the wave equation. We will briefly derive the important features of the model as well as account for the error introduced by common approximations that are made. Typically one does not get an image that is approximately the target distribution, but rather an image that is approximately proportional to the target distribution. This means that there is a scaling parameter that must be chosen when using target distribution estimates to correct data. We will discuss methods for choosing this parameter. We will provide a few basic SAR imaging methods and perform simulation using the Gotcha Data set in combination with the iterative technique. At the end of the paper we will discuss future work involving this method.

8857-3, Session 1

An examination of the application of coherent and space time adaptive processing for the detection of maritime surface targets from high altitude airborne platforms

Michael K. McDonald, Defence Research and Development Canada, Ottawa (Canada); Delphine Cerutti-Maori, Fraunhofer FHR (Germany)

Airborne wide area, maritime surface surveillance is traditionally undertaken using non-coherent, high bandwidth, radar systems operating from low altitude aircraft at low grazing angles. The planned migration by numerous countries of maritime surveillance activities to high altitude platforms, such as HALE/MALE UAVs, will result in operational performance shortfalls as non-coherent approaches will fail to detect small targets due to the order of magnitude increases in sea clutter radar cross section associated with high grazing angle geometries. This paper examines the application of coherent and Space Time Adaptive Processing (STAP) techniques to FHR PAMIR, multi-channel, medium grazing angle, real radar sea clutter data and the ability of these techniques to mitigate aforementioned performance deficiencies. Application of coherent approaches to maritime surveillance is significantly complicated by non-stationarity of sea clutter and rapid variations of clutter spectrums due to transient wave activity. The observed performance gains from maritime STAP are much more limited than those observed for Ground Moving Target Indication (GMTI) due to the inherent spectral width of sea clutter and the slow Doppler velocities of maritime targets. The impact of clutter non-stationarity across the background samples used to form the sample clutter covariance matrix is also examined. The performance of four sub-optimal STAP processing algorithms is examined and the performance differences quantified and explained in terms of the unique characteristics of sea clutter's inherent rank and spectral variability. The preferred suboptimal approach is identified and shown to provide a more practical real world implementation than theoretically ideal fully adaptive STAP.

8857-4, Session 1

Infrared small target detection technology based on OpenCV

Lei Liu, Zhijian Huang, Jilu Chen, Nanjing Univ. of Science and Technology (China)

With the continuous development of science and technology, infrared imaging technology has played an important role in national defense, medical, transportation and other areas. The detecting technology of small infrared target is an important branch of infrared imaging technology, which has not only very important scientific research value, but also has broad application prospect in the military and civil area.

Nowadays, different algorithms have been proposed for infrared target detection. However, under complex backgrounds, such as clutter, varying illumination, and occlusion, the traditional detection method often loses the real infrared small target.

To cope with these problems, firstly we have proposed four infrared target detection algorithms to enhance the detection performance according to the characteristics of the small target in infrared images, namely, traditional two-frame difference method, improved three-frame difference method, background estimation and frame differential fusion method, and building background with neighborhood mean method. Secondly, infrared small target detecting software is developed by a human-computer interaction interface created by MFC in VC++ combined with many functions in OpenCV so as to realize these four detecting algorithms. Lastly, a performance assessment conclusion is

made by analyzing the experiment results. The experimental results show that, compared with the traditional algorithm, the presented method greatly improves the accuracy and effectiveness of infrared target detection under complex scenes, and the results are satisfactory. It is of great significance for actual application of small infrared target detecting technology.

8857-5, Session 1

Improving variance estimation ratio score calculation for slow moving point targets detection in infrared imagery sequences

Revital Huber-Shalem, Ofer Hadar, Stanley R. Rotman, Merav Huber-Lerner, Ben-Gurion Univ. of the Negev (Israel)

Infrared (IR) imagery sequences are commonly used for detecting moving targets in the presence of evolving cloud clutter or background noise. This research concentrates on slow moving point targets that are less than one pixel in size, such as aircraft at long ranges from a sensor.

The target detection performance is measured via the variance estimation ratio score (VERS), which essentially calculates the pixel scores of the sequences. VERS uses two parameters – long and short term windows, which were predetermined individually for each movie, depending on the target velocity and on the clouds intensity and amount, as opposed to clear sky (noise), in the background. In this work, we examine the correlation between the sequences' spatial and temporal features and these two windows. In addition, we modify VERS calculation, to enhance target detection and decrease cloud-edge scores and false detection.

We conclude this work by evaluating VERS as a detection measure, using these two modifications. The test sequences are both original real IR sequences as well as their relative compressed sequences using the temporal DCT quantization method.

8857-6, Session 1

Identification of Human Motion Signature using Airborne Radar Data

Michael K. McDonald, Anthony Damini, Defence Research and Development Canada, Ottawa (Canada)

Data containing the radar signatures of moving persons on the ground, also known as dismounted targets, were collected at a range of 30 km from a moving airborne platform using the DRDC Ottawa X-band Wideband Experimental Airborne Radar (XWEAR). The dismounted target radar echo returns were found to possess a characteristic amplitude and frequency modulated signature which could be usefully characterised in terms parameters corresponding to the mean Doppler of the target, amplitude modulation (AM) index, frequency modulation (FM) index, FM frequency, AM frequency and the phase shift between the modulation frequencies. Examination of detection performance after space time adaptive processing revealed that performance is limited by false alarms corresponding to clutter discretes arising from large radar cross-section scatterers which are not effectively canceled during the whitening step. The clutter discretes are observed to possess different modulation characteristics from the dismount targets discussed above and the ability of pattern classification techniques to use this parameter measurement space to distinguish between dismounted targets and clutter discretes is explored and preliminary results presented. The requirement for wide area surveillance with frequent revisit and refresh of detection contacts is in conflict with the desire to use long dwells on the targets to obtain accurate parameter estimates. To this end an examination is made of the ability to extract sufficiently accurate measurements of the corresponding characteristic parameters for dismounts and clutter discretes while the radar is operated in a mode consistent with wide area surveillance.

8857-7, Session 1

Method for measuring the parameters of surface by analyzing the pulse shape of the second harmonic of laser radiation

Rustam Rysov, Vadym M. Prokopets, National Taras Shevchenko Univ. of Kyiv (Ukraine)

Investigation the parameters of solid surfaces by registering generated second harmonic of the laser radiation is very informative method. These data may help to determine the symmetry elements of the surface structure or thin film like the charge of surface or interface states, the energy spectrum of surface electrons roughness, etc. Using pulsed laser sources in optical researches allows to investigate the properties of substances for which long-term impact of intense radiation can result to destruction of the structure of matter.

Our complex was made for precise and fast registration of short light pulses from a low repeat rate for further processing.

It was developed software and hardware complex for registration first and second harmonic of laser radiation and transfering data to a computer via USB.

Wide bandwidth and differential structure of the device allows user to change the input dynamic range and offset. The hardware part of the complex was based in ARM microcontroller. This measure made up to 0.5 millivolts per in the time interval from 10 nanoseconds.

The circuit includes two input channels for measuring voltage, ADC's and start signal detection part.Data is transmitted to a computer via USB.

With this method it is possible to measure the parameters of completely different samples, such as solid structures, optical films, nanostructures or heterostructures, and metamaterials.

In this paper demonstrated the results of measurements Si-Ge heterostructure with nanoislands. Used a neodymium laser with a wavelength of 1064 nm for second harmonic generation.

8857-8,

Conference overview

Oliver E. Drummond, CyberRnD, Inc. (United States)

This conference overview addresses the types of targets and the major characteristics of the data encountered in processing sensor data of these targets. The presentation summarizes why tracking these targets make the processing of this data so complex and challenging. The discussion includes a view of the algorithm state of the art, the current drivers in algorithm development, and the critical open issues. Future direction of this series of conferences is discussed and audience suggestions are invited.

8857-9, Session 2

Particle filter tracking for the banana problem

Kevin Romeo, Peter Willett, Yaakov Bar-Shalom, Univ. of Connecticut (United States)

In this paper we present an approach for tracking with a high-bandwidth active sensor in very long range scenarios. We show that in these scenarios the extended Kalman filter is not desirable as it suffers from major consistency problems, and that many types of particle filters may suffer from a loss of diversity among particles after resampling. This leads to sample impoverishment and the divergence of the filter. In the scenarios studied, this loss of diversity can be attributed to the very low process noise. However, a regularized particle filter is shown to avoid this diversity problem while producing consistent results. The regularization is accomplished using a modified version of the Epanechnikov kernel.

8857-10, Session 2

Particle flow with non-zero diffusion for nonlinear filters, Bayesian decisions and transport

Frederick E. Daum, Jim Huang, Raytheon Co. (United States)

We solve the transport problem in high dimensions by computing the flow of particles induced by Bayes' rule with a linear constant coefficient first order highly underdetermined PDE, similar to the Gauss divergence law. We pick a unique solution to this highly underdetermined PDE by using an upper triangular Jacobian of the flow, inspired by Knothe-Rosenblatt transport. One might call this "differential Knothe-Rosenblatt transport". We solve this PDE using the Fourier transform, but we avoid computing the inverse Fourier transform by use of Monte Carlo integration and the generalized matrix inverse (roughly analogous to a pseudodifferential operator). We show numerical results for high dimensional nonlinear filter problems (d = 1 to 30) with a wide variety of parameters (stable and unstable plants, initial uncertainty of the state vector, measurement accuracy, and dimension of the plant). This algorithm works for arbitrary smooth nowhere vanishing probability densities, including highly non-Gaussian multimodal densities, and hence the theory can be applied to essentially any estimation or Bayesian decision problem. We solve the fundamental and well known problem of particle degeneracy by using a log-homotopy of the conditional probability density, but we do not use resampling of particles or a proposal density, and we do not use Metropolis-Hastings or MALA or Hamiltonian Monte Carlo or any other Markov chain Monte Carlo method (MCMC), and our method is not anything like variational Bayes algorithms. It turns out that it is crucial to select an optimal set of points in k-space at which to evaluate the Fourier transform, and somewhat surprisingly we must enforce neutral charge density of particles to very high accuracy along the flow in order to guarantee the existence of a solution to our linear underdetermined PDE. Our algorithm is roughly ten orders of magnitude faster than standard particle filters for the same estimation accuracy.

8857-11, Session 2

A survey of maneuvering target tracking, part VId: sampling-based nonlinear filtering

Xiao-Rong Li, Vesselin P. Jilkov, Univ. of New Orleans (United States)

This paper is Part VId of a comprehensive survey of maneuvering target tracking without addressing the so-called measurement-origin uncertainty. It provides an in-depth coverage of various sampling-based nonlinear filters, commonly referred to as particle filters, developed particularly for handling the uncertainties induced by potential target maneuvers as well as nonlinearities in the dynamical systems commonly encountered in target tracking. Various implementations and tracking applications are reviewed. Some computational issues, such as different resampling schemes and parallel processing are addressed.

8857-12, Session 2

Estimability of thrusting trajectories in 3D from a single passive sensor with unknown launch location

Ting Yuan, Yaakov Bar-Shalom, Peter Willett, R. Ben-Dov, S. Pollak, Univ. of Connecticut (United States)

The problem of estimating the state of thrusting/ballistic endoatmospheric projectiles moving in 3-dimensional (3-D) space using 2-dimensional (2-D) measurements from a single passive sensor (stationary or moving with constant velocity) with unknown launch location is investigated. The unavailable knowledge of launch point (LP), which is a crucial practical issue for a correct and accurate impact point prediction (IPP), exacerbates the ambiguity problem that could exist in estimation. The estimability is analyzed based on the Fisher Information Matrix (FIM) of the target parameter vector, comprising the unknown LP height, initial launch (azimuth and elevation) angles, drag coefficient and thrust, which determine its trajectory according to a nonlinear motion equation. The full rank of the FIM ensures that one has an estimable parameter vector. The corresponding Cram{'{e}}r-Rao lower bound (CRLB) quantifies the estimation performance of the estimator that is statistically efficient and can be used for IPP. In view of the inherent nonlinearity of the problem, the maximum likelihood estimate (MLE) of the target parameter vector is found by using the iterated least squares (ILS) numerical approach. A drag-coefficient-thrust-height grid-based ILS search over the launch angles space is proposed. The grid-based ILS approach is shown to converge to the global maximum and its reliable estimation performance. This is then used for IPP.

8857-13, Session 2

A minimalist approach to bias estimation for passive sensor measurements with targets of opportunity

Djedjiga Belfadel, Richard. W. Osborne III, Yaakov Bar-Shalom, Univ. of Connecticut (United States)

In order to carry out data fusion, registration error correction is crucial in multisensor systems. This requires estimation of the sensor measurement biases. It is important to correct for these bias errors so that the multiple sensor measurements and/or tracks can be referenced as accurately as possible to a common tracking coordinate system. This paper provides a solution for bias estimation for the minimum number of passive sensors (two), when only targets of opportunity are available. The sensor measurements are assumed time-coincident (synchronous). Since these sensors provide only line of sight (LOS) measurements, the formation of a single composite Cartesian measurement obtained from fusing the LOS measurements from different sensors is needed to avoid the need for nonlinear filtering. The evaluation of the Cramer-Rao Lower Bound (CRLB) on the covariance of the bias estimate, i.e., the quantification of the available information about the biases, combined with simulations, shows that this method is statistically efficient, even for small sample sizes (as few as two sensors and six points on the trajectory of a single target of opportunity). We also show that RMS position error is significantly improved with bias estimation compared with the target position estimation using the original biased measurements.

8857-25, Session 2

On covariance structure in noisy, big data

Randy Paffenroth, Ryan Nong, Philip C. Du Toit, Numerica Corp. (United States)

Herein we describe theory and algorithms for detecting covariance structures in large, noisy data sets. Our work uses ideas from compressed sensing, matrix completion, and robust principal component analysis to detect the presence of low-rank covariance matrices, even when the data is noisy, distorted by large corruptions, and only partially observed. In fact, the ability to handle partial observations, combined with ideas from randomized algorithms for matrix decomposition, are the key enablers for producing asymptotically fast algorithms. While such methods have applicability to many problems, including mathematical finance, crime analysis, and other large-scale sensor fusion problems, our focus will be on applying these methods in the context of cyber network intrusion detection. In particular, our goal is to use such methods to detect anomalies in large-scale cyber data (e.g. pcap, NetFlow, etc.).

8857-22, Session P1

Estimating the quality of the software for inclusion recognizing and analyzing in semiconductor crystals

Liliya Dyachenko, Eugen Minov, Sergey E. Ostapov, Petro M. Fochuk, Oleg Kopach, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Aleksey E. Bolotnikov, Ralph B. James, Brookhaven National Lab. (United States)

In this paper, we discuss our software implementation for a series of infrared images that recognize and reveal the three-dimensional structures of defects in semiconductor crystals. Such programs often are used to explore the quality of various crystals, for example, CdTe and CdZnTe.

Despite the potential value of such crystal-recognition programs, one major problem here is whether researchers can confidently use them, because it is impossible to grow crystals with predetermined properties that can be used as a standard. There is another way to calibrate these programs to assure the trustworthiness of such recognition, viz., detecting a recognition threshold and acquiring a detailed knowledge of the influence of the parameters on the IR images. This task involves creating a program for generating "virtual crystals" with predetermined parameters of defects and comparing the "pictures" received from them with the properties of the virtual crystals.

Modeling the structure of defects in a semiconductor crystal is based on a series of infrared images that are stored in the *.jpg format. The software first undertakes the recognition of defects in the proposed images, and then builds a three-dimensional image of a subsystem of defects. The developed software provides tools for editing images, allowing defects originating from surface irregularities and defects of the image itself to be wiped out. The system offers the ability to display a specific group of defects, so allowing a view of only those specific extended defects that interest the user. The constructed three-dimensional image is rotatable via the computer's mouse.

8857-23, Session P2

Study on comparison and validation of the measured and simulated IR signal using the scaled model ship

Dong-Geon Kim, Kuk-Il Han, Jun-Hyuk Choi, Tae-Kuk Kim, Chung-Ang Univ. (Korea, Republic of)

The primary goal of the present study is to develop a S/W that predicts infrared signals from objects by synthetically considering the internal and external factors, such as surface properties, internal heat sources, solar irradiations, atmospheric temperature, etc. As a part of developing a S/W, this paper contains some results of the measured and simulated IR signals to comparing and validating. The scaled model ship used in this study is made of 5mm-thick steel and 1.5m long(scaled down by 1/100). It has virtual internal heat sources that are made of brass. At first, the surface temperature of the scaled model ship is measured in an indoor environment. The radiance from the ship is mainly based on the surface temperature because the effects of solar and wind are excluded in an indoors. Also the IR signals are collected by the IR cameras which are operated at MWIR(3~5µm and LWIR(8~9.2µm), respectively. At the same time, additionally, the atmospheric temperature and the relative humidity are measured to use for input conditions of calculation. The surface temperature and the IR signals within the two wavelengths are calculated by the S/W developed in this study with considering same conditions: the 3D ship model, the internal heat source temperature, the atmospheric temperature, and the relative humidity. The temperature and IR signals from the scaled model ship obtained from measurements and by using the S/W developed in this study are compared each other. The results show fairly good agreement with those obtained from measurements.

8857-24, Session P2

Research on pre-processing algorithm for transient electromagnetic signal

Huinan Zhao, Lingjia Gu, Ruizhi Ren, Jian Sun, Jilin Univ. (China)

Transient electromagnetic method (TEM) is regarded as an everlasting issue for geological exploration. The signal acquisition systems based on transient electromagnetic theory are widely used in many research fields, such as mineral exploration, hydrogeology survey and engineering exploration. The principle of transient electromagnetic method is to establish a first pulse magnetic field underground through the ungrounded loop with pulse current. During the period of the magnetic field downward diffusion, if the magnetic field encounters a good conductive geological body under the ground, it will produce eddy current in the geological body. A new magnetic field can be further induced in the geological body due to the eddy current changing with times, which is called the secondary magnetic field. Within the first pulse magnetic field intermittent, the receiver coil will couple with the secondary magnetic field. Through the late inversion process, the signal of underground conductor can be obtained. However, there are many serious random disturbance signals, namely, noises in the secondary field signal of the transient electromagnetic measurement system, which cause calculation errors in the late inversion. To solve this problem, an effective pre-processing algorithm for transient electromagnetic signal based on Labview virtual instrument development platform is proposed in the paper, which includes signal abnormality judgment, signal-to-noise ratio (SNR) judgment, signal superposition denoising, wavelet threshold denoising and wavelet packet denoising. The test results demonstrated that the proposed preprocessing algorithm can effectively eliminate serious disturbance signals from the test transient electromagnetic data, which can ensure efficiency of transient electromagnetic data in the late work.

8857-15, Session 3

Detection of unusual trajectories using multi-objective evolutionary algorithms and rough sets

Tomasz G. Smolinski, Trevor Newell, Samantha McDaniel, David D. Pokrajac, Delaware State Univ. (United States)

Detection of unusual trajectories of moving objects (e.g., people, automobiles, etc.) is an important problem in many civilian and military surveillance applications. The problem can be considered a two-class classification/prediction task: given a set of characteristic trajectories, can we build a classifier capable of recognizing typical, but yet unseen trajectories, and identify those that seem suspicious? Classificatory decomposition (CD) is a multi-objective evolutionary algorithms and rough sets-based signal decomposition technique that breaks down the original signals (e.g., 2-dimensional trajectories) into a set of additive components. However, instead of assuming orthogonality (as in Principal Component Analysis) or statistical independence (as in Independent Component Analysis) in the process of decomposition, the algorithm attempts to extract a small number of components (also called basis functions) that are most useful for the underlying classification problem. The main assumption in CD is that the basis functions are relatively constant for all of the observable signals (e.g., various aspects of movement across a scene), but are expressed differently due to some underlying classification scheme (e.g., typical vs. unusual trajectory). The variation of expression of the basis functions between different classes is characterized by the differences in the coefficients. A new trajectory is represented in the space spanned by the basis functions generated from the training set, and by matching it against a simple classifier, we can determine if said trajectory is typical, or if, perhaps, attention of a human operator is required. We test our approach on publicly available datasets, including the SENSIAC database.

8857-16, Session 3

Optical sensor pixel size selection from a tracking perspective

Richard W. Osborne III, Xin Zhang, Peter Willett, Yaakov Bar-Shalom, Univ. of Connecticut (United States)

This paper considers the selection of the resolution cell (pixel) size for the detection and tracking of point targets in the focal plane (FP) of an imaging sensor. For smaller pixels, the signal power in each resolution cell becomes lower, because a point target is recorded as a blur according to the point spread function (PSF). Meanwhile, since the noise power is proportional to the area of the resolution pixel, the noise is also lower. On the other hand, using a coarser resolution (which is the result of opting for a high signal power in the resolution cell) results in higher noise power. The various pixel sizes will also impact the measurement extraction scheme and result in varied levels of measurement noise, which will impact the target tracking accuracy. Therefore, as the pixel size changes, there is a trade-off in terms of detection performance versus estimation accuracy. The choice of pixel size is examined here from the perspective of maximizing the overall tracking accuracy. The pixel-size effects on the probability of detection and the measurement extraction accuracy (the FP position measurement noise variance) are analyzed. Expressions that allow calculation of these key quantities, necessary for the design of advanced tracking filters, are given. The impact of pixel size, target strength (SNR) and target motion uncertainty (its ``maneuvering index") on the tracking accuracy are quantified and illustrated with simulations.

8857-17, Session 3

Major challenges and rewards in improving fusion processing

Oliver E. Drummond, CyberRnD, Inc. (United States)

While small target signal and data processing has matured greatly, especially during the last twenty-five years, there still appears to be opportunities for substantial improvement in signal and data processing functional performance. This improvement in performance may require a substantial effort to deal with potentially very complex processing issues.

While this paper concentrates on fusion, the opportunities for improvement appears to extend to processing systems without fusion, however, the relative amount of improvement may be less. Three specific processing approaches for improvement in functional performance are addressed here. They are adaptive sensor data fusion; integration and interaction of the processing of sensor data fusion functions; and advanced fuse-before-detect. To help simplify the discussion, a distinction is made between sensor data fusion and multiple sensor tracking. The difference is that sensor data fusion includes functions that take advantage of multiple sensor tracks to improve target typing/classification plus resource management, such as communications, processing, and weapon resources.

8857-18, Session 3

Target track extraction in high false density environments using multiple hypothetical frame selection MLPDA

Masanori Mori, Takashi Matsuzaki, Hiroshi Kameda, Toru Umezawa, Mitsubishi Electric Corp. (Japan)

MLPDA (Maximum Likelihood Probabilistic Data Association) has been attracted as an effective target track extraction algorithm in high false density environments. In this algorithm, the target track is estimated as the maximum likelihood state vector, by using multiple observation frames which include the target signal and many false signals. The track is confirmed whether it is the true target or not, by comparing its likelihood with a given track confirmation threshold. However, when the target signals are lost at several frames, the conventional MLPDA deteriorates the track estimation accuracy due to false signals in frames without the target signal.

In this paper, we propose multiple hypothetical frame selection MLPDA, which can extract the target track under the situation where the target signals are lost in several frames. In particular, a batch of stored frames is first selected for track extraction. If the track is not confirmed, our algorithm offers multiple frame selection hypotheses where some frames are assumed as the frames without the target signal and the other frames include the target signal. The track is extracted under these hypotheses respectively, and the most-likely hypothesis is accepted. If all hypotheses are rejected, our proposed method generates hypotheses that increase the number of frames without the target signal, and verifies them again. Furthermore, the hypotheses which have likelihoods above a given threshold are retained in order to modify the wrong frame selection later. Simulation results show the validity of our proposed method.

8857-19, Session 3

Directional sensor control for maximizing information gain

Shankarachary Ragi, Colorado State Univ. (United States); Hans D. Mittelmann, Arizona State Univ. (United States); Edwin K. P. Chong, Colorado State Univ. (United States)

Directional sensors (e.g., surveillance cameras, infrared sensors, and ultrasound sensors) are gaining importance due to applications including surveillance, detection, and tracking. We develop tractable solutions to the problem of controlling multiple 2-D directional sensors for maximizing information gain corresponding to multiple targets located on a 2-D plane. The location of the targets is known with uncertainty given by a joint a-priori distribution (Gaussian), and the sensor locations are known exactly. A directional sensor has a limited field-of-view (FOV), where the area sensed by the sensor is given by a sector in a circular region around the sensor. The direction of a sensor can be controlled, which can take several discrete values. A directional sensor generates a measurement of a target if and only if the target lies within the FOV of the sensor. We have a notional fusion center where the measurements from all the sensors are fused. Our goal is to assign each sensor to a particular angle such that the overall information gain is maximized. This problem is hard to solve exactly because of its combinatorial nature—the computation time increases exponentially with the number of sensors. We develop heuristic approaches that are tractable and give sub-optimal solutions, and also provide lower bounds on the optimal information gain. We also solve a relaxed version of the problem that yields an upper bound on the optimal information gain. We conduct an empirical study to compare the performance of these approaches.

8857-20, Session 3

Efficient multiple emitter localization for fully decentralized large-scale/low-cost multimodal sensor networks

Philip J. Haney, BAE Systems (United States); Paul D. Fiore, MIT Lincoln Lab. (United States)

Recent advances in wireless communications and sensing technologies have led to ongoing interest in developing large-scale sensor networks for detecting, localizing and tracking emitters of interest for wide-area persistent surveillance applications. In order for such large-scale networks to be feasible, low-cost becomes paramount and is typically achieved through the incoherent combination of inexpensive sensors dispersed throughout the surveillance region of interest. Since low-cost sensors stereotypically exhibit multimodal characteristics, achieving accurate emitter localization and tracking performance throughout the network presents a challenging problem. Typical multimodal localization methodologies using simple intersection approaches frequently produce

sub-optimal performance generating numerous false tracks ultimately leading to significant degradation in tracking performance. Alternatively, more robust methods for performing multimodal localization have been proposed; however, these methods rooted in computationally expensive operations such as Sequential Monte Carlo Methods and multiple hypothesis tracking are not suited for large-scale, low-cost sensor network applications. As a result, this paper adopts both a robust and computationally efficient approach to the multimodal localization problem by generating a pseudo maximum likelihood (PML) function from available sensor measurements in which the peaks of this function strongly indicate the number and locations of the true emitters. Localization is performed by first iteratively associating the individual sensor measurements to the PML peaks and then generating true maximum likelihood estimates of the emitter locations based on the associated measurements. These emitter location estimates are fed to an EKF-based, decentralized architecture for initiating, sustaining and sharing local track activity throughout the sensor network. Simulation results illustrate the ability of the proposed localization approach to generate accurate emitter location estimates in cluttered environments for supporting all track activity in large-scale, fully decentralized, multimodal sensor networks.

8857-21, Session 3

Multitarget tracking using ABIR images and the H-PMHT

Balakumar Balasingam, Peter Willett, Univ. of Connecticut (United States); Darin T. Dunham, Terry Ogle, Vectraxx, Inc. (United States)

In this paper, we address the problem of passive tracking of multiple targets with the help of images obtained from airborne infrared (ABIR) platforms. Conventional approach to this problem, which involves thresholding, measurement detection, data association and filtering, encounters problems in every steps due to the fact that the target energy is spread in multiple cells of the ABIR imagery. A histogram based probabilistic multi-hypothesis tracking (H-PMHT) approach provides an automatic means of modeling targets that are spread in multiple cells in the imaging sensor(s) by relaxing the need for hard decisions on measurement detection and data association. With the help of simulated ABIR images from multiple platforms, we demonstrate the applicability of H-PMHT for tracking 3D targets.

8858-1, Session 1

Image inpainting: theoretical analysis and comparison of algorithms

Emily J. King, Gitta Kutyniok, Technische Univ. Berlin (Germany); Xiaosheng Zhuang, City Univ. of Hong Kong (China)

An issue in data analysis is that of incomplete data, for example a photograph with scratches or seismic data collected with fewer than necessary sensors. There exists a unified approach to solving this problem and that of data separation: namely, minimizing the norm of the analysis (rather than synthesis) coefficients with respect to particular frame(s).There have been a number of successful applications of this method recently. Analyzing this method using the concept of clustered sparsity leads to theoretical bounds and results, which will be presented. Furthermore, necessary conditions for the frames to lead to sufficiently good solutions will be shown, and this theoretical framework will be use to show that shearlets are able to inpaint larger gaps than wavelets. Finally, the results of numerical experiments comparing this approach to inpainting to numerous others will be presented.

8858-2, Session 1

Sparse representations for the morphological reconstruction of neurons from fluorescent microscopy images

Manos Papadakis, David Jimenez, Paul Hernandez-Herrera, Burcin Ozcan, Demetrio Labate, Univ. of Houston (United States); Fernanda Laezza, The Univ. of Texas Medical Branch (United States); Ioannis A. Kakadiaris, Univ. of Houston (United States)

We present a number of algorithms for segmenting the image of a live neuron from its background and for extracting dendritic/axonal centerlines and for identifying other important anatomical and functional elements of the post and pre-synaptic network. The input images are acquired with confocal or multiphoton microscopes. We demonstrate how a sparse representation can be designed by mixing isotropic filters which work as singularity detectors with directionally selective shearlet filters. We also report on our ongoing and recent experiments.

8858-3, Session 1

Parabolic molecules: curvelets, shearlets, and beyond

Gitta Kutyniok, Technische Univ. Berlin (Germany); Philipp Grohs, ETH Zürich (Switzerland)

Anisotropic representation systems such as shearlets and curvelets have had a significant impact on applied mathematics in the last decade. The main reason for their success is their superior ability to optimally resolve anisotropic structures. By now, a large variety of such anisotropic systems has been introduced such as curvelets and shearlets. In this talk we will introduce the concept of parabolic molecules which allows for a unified framework encompassing all known anisotropic frame constructions based on parabolic scaling. The main result essentially states that all such systems share similar sparse approximation properties.

8858-4, Session 1

A multiscale representation for efficient inference on permutations

Yue M. Lu, Harvard Univ. (United States)

Uncertainties over permutations are encountered in many problems, such as tracking, voting, and ranking. The factorial size of the permutation group makes efficient statistical inference a challenging problem. Fourier-theoretical ideas have been explored, since at least the 1980s, as a useful tool for tractable and approximate inference over permutations. We present our preliminary results on constructing an adaptive multiscale representation on the permutation group, achieving better trade-offs between accuracy and complexity than Fourier transforms.

8858-5, Session 1

A split-augmented Lagrangian algorithm for spectral factorization of a set of 2D directional filters and application to the design of compact shearlet frames

Bart Goossens, Jan Aelterman, Hiep Q. Luong, Aleksandra Pižurica, Wilfried Philips, Univ. Gent (Belgium)

In this paper, we first briefly review the directional properties of the Dual-Tree complex wavelet transform and we explain how the the directional selectivity of the transform can be increased (i.e., to obtain more than 6 orientations per scale). Inspired by this approach, we describe a new augmented Lagrangian optimization algorithm to jointly perform the 2D spectral factorization of a set of 2D directional filters, with high numerical accuracy. We demonstrate how this approach can be used to design compactly supported shearlet frames that are almost tight. Finally, a number of experimental results are given to show the merits of the resulting shearlet frames.

8858-6, Session 1

Optimal restoration of noisy 3D x-ray data via Shearlet decompositions

Demetrio Labate, Univ. of Houston (United States); Glenn R. Easley, System Planning Corp. (United States); Kanghui Guo, Missouri State Univ. (United States)

In a recent work, it was shown that the shearlet representation provides a useful formula for the reconstruction of 3D objects from their X-ray projections. One major advantage of this approach is that it yields a near-optimal rate of convergence in estimating piecewise smooth objects from 3D X-ray projections which are corrupted by white Gaussian noise. In this work, we provide extensive numerical demonstrations to illustrate the effectiveness of this method and its performance as compared with other state-of-the-art X-ray data restoration algorithms.

8858-7, Session 2

Interplay in various settings between translation invariant spaces, sampling, and wavelets *(Keynote Presentation)*

Guido L Weiss, Edward N Wilson, Peter M Luthy, Washington Univ. in St. Louis (United States)

We will begin with the description of principal translation invariant spaces

in L^2 (R) and their representation by weighted spaces L^2([-1/2,1/2), p). We extend these results to higher dimensions and describe their role in sampling and wavelet theory. We then generalize these results to higher dimensions and to the setting of more general spaces acted upon by locally compact abelian groups and their duals. We finish by further extending these results to certain non-abelian groups including the Heisenberg group.

8858-8, Session 3

Eigenvector localization, random matrices, and Banach algebras

Thomas Strohmer, Univ. of California, Davis (United States)

The phenomen of eigenvector localization has confounded mathematicians and physicists for more than half a century. Its most famous manifestation is known under the name of Anderson localization. I will report on recent progress on eigenvector localization at the interface of random matrices and Banach algebras. We are now able to give precise predictions about the qualitative and quantitative localization behavior of eigenvectors based on the localization characteristics of the matrix and certain properties of the spectrum.

8858-9, Session 3

Which sensing matrices allow for stable compressed sensing?

Dustin G. Mixon, Air Force Institute of Technology (United States); Jameson Cahill, Peter G. Casazza, Univ. of Missouri-Columbia (United States)

In compressed sensing, it is popular to reconstruct sparse signals using L1 minimization. In this setting, the null space property (NSP) is necessary and sufficient for unique recovery, whereas the restricted isometry property (RIP) is sufficient for stability. In this talk, we consider a different notion of stability, and we identify a new matrix property which guarantees this stability. In particular, we identify that a well-conditioned sensing matrix can be beneficial, despite not being required by RIP. This leads to new constructions of "good" sensing matrices, while at the same time motivating the construction of tight frames for compressed sensing.

8858-10, Session 3

Spectral methods for extracting localized features from dual data

Nate K. Strawn, Duke Univ. (United States)

Deep learning has been making fast gains since the work of Hinton, Osindero, and Teh (2006). Their fast stochastic gradient descent method for training layers of restricted Boltzmann machines produced the best results (for their time) on classification of image data sets. Inspired by the fact that the first layers of Hinton et al.'s tend to learn features similar to directional filters, Lee, Grosse, Raganath, and Ng (2009)combined the RBM model with Lecun's convolutional neural networks to further break classification records on image data sets. These deep learning results represent incremental steps towards fully utilizing the natural pixel (or dual data) topology of images. For more exotic data sets, the underlying geometry of the dual data is not readily available. In our work, we demonstrate from theory and practice that spectral methods provide a bountiful framework for discovering generic dual data topologies and extracting localized (sparsely supported) features.

8858-11, Session 3

Sub-Gaussian random frames, Sobolev duals, and root-exponential accuracy for sigma-delta quantization

Ozgur Yilmaz, The Univ. of British Columbia (Canada); Felix Krahmer, Univ. Sternwart Göttingen (Germany); Rayan Saab, Duke Univ. (United States)

There is a rich literature on frame quantization, though the main focus has been on structured frames. Motivated by compressed sensing we focus on unstructured sub-Gaussian random frames. We show that by using sigma-delta quantizers along with reconstruction via "Sobolev duals", we can effectively quantize sub-Gaussian frame expansions. Specifically, we prove that using an r-th order sigma-delta scheme, we get an accuracy of order (-r)-th power of the "aspect ratio" of the frame. Furthermore, if we optimize the order of the scheme depending on the aspect ratio, this yields root-exponential accuracy.

8858-12, Session 3

Exact signal recovery from thresholded measurements

Friedrich Philipp, Holger Boche, Gitta Kutyniok, Mijail Guillemard, Technische Univ. Berlin (Germany)

We study the exact recovery of signals from linear measurements which are erased when their magnitude is smaller than a given threshold parameter.

8858-13, Session 4

Dynamical sampling: exact reconstruction from sensing networks

Akram Aldroubi, Vanderbilt Univ. (United States)

Let $Vsubset L^2$ be a shift invariant subspace and $fin V$ be an initial distribution that is evolving in time under the action of a family of (spatially) invariant evolution operators ${A_t}_{tin [0,infty)}$:

begeqlabel{evo1}

f_t(x) = (A_t f)(x).

end{equation}

Let X_m be the set $mmathbb Z$, $minNN$. We study the conditions under which $f=f_0$ can be recovered from the samples ${ f(X_m),(A_1 f)(X_m),dots, (A_T f)(X_m)}cup {f(Omega)}$ in a stable way, where $Omegasubset ZZ$ is a small extra sampling sets judiciously chosen.

This work is in Collaboration with Jacque Davis and Ilya Krishtal

8858-14, Session 4

Random fusion frames for loss-insensitive packet encoding

Bernhard G. Bodmann, Univ. of Houston (United States)

This talk describes recent results on fusion frame design which are motivated by communication theory. Fusion frames are a natural tool for the linear encoding of an analog signal in packets that are transmitted through a network. The possible linear dependencies among vectors from the subspaces of a fusion frame incorporate redundancy in the encoded components of an analog signal, which allows to test the integrity of the transmitted data and to correct errors, for example the loss of part of the packets during the transmission. Essential techniques for fusion frame design in this context come from the literature on compressed sensing.

8858-15, Session 4

Preconditioning of frames

Gitta Kutyniok, Technische Univ. Berlin (Germany); Friedrich Philipp, Technische Univ. Clausthal (Germany); Kasso A. Okoudjou, Univ. of Maryland, College Park (United States)

Frames which are tight might be considered optimally conditioned concerning their numerical stability. This leads to the question of perfect preconditioning of frames, i.e., modification of a given frame to generate a tight frame. In this talk, we analyze prefect preconditioning of frames by a diagonal operator. We derive various characterizations of functional analytic and geometric type of the class of frames which allow such a perfect preconditioning.

8858-16, Session 4

Theoretical bounds on reconstruction from magnitudes of frame coefficients

Radu V Balan, Univ. of Maryland, College Park (United States)

We will present recent results about injectivity of the nonlonear map alpha:C^n -> R^m , (alpha(x))_k = |< x,f_k>|.

8858-17, Session 5

Sampling theory, wavelets, and sparse reconstruction on the sphere

Jason D. McEwen, Univ. College London (United Kingdom); Yves Wiaux, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

We review recent developments in signal processing on the sphere, focusing on three related areas. Firstly, we discuss a novel sampling theorem on the sphere which halves the Nyquist rate on the sphere for equiangular sampling schemes. Secondly, we describe exact wavelet transforms on the sphere built from a tiling of harmonic space. Our novel sampling theorem leads to faster and more efficient algorithms to perform wavelet transforms on the sphere. Thirdly, we consider the application of the aforementioned methods for sparse reconstruction on the sphere.

8858-18, Session 5

Flaglets on the ball for studying the large-scale structure of the Universe

Boris Leistedt, Jason D. McEwen, Univ. College London (United Kingdom)

We define the Fourier-Laguerre transform -- a novel transform on the three-dimensional ball -- by combing the spherical harmonics on the sphere with damped Laguerre polynomials on the radial line. Unlike the Fourier-Bessel expansion, the Fourier-Laguerre transform admits a sampling theorem. We construct exact wavelets on the ball through a tilling of the Fourier-Laguerre harmonic space. The resulting ‘flaglets’ may be used to extract scale-dependent, spatially localised features from data defined on the ball. We use flaglets to study the statistical properties of clusters and voids in galaxy surveys and to constrain models of the large-scale structure of the universe.

8858-19, Session 5

3D sparse representations on the sphere and applications in astronomy

Jean-Luc Starck, Commissariat à l’Énergie Atomique (France); Francois Lanusse, Commissariat à l’Energie Atomique (France)

We present several 3D sparse decompositions based on wavelets and curvelets on the sphere that are useful for different kind of data set such as regular 3D spherical measurements (r, theta, phi), multichannel spherical measurements (lambda, theta, phi) or polarized data (stokes parameter, theta, phi). We show how these new decompositions can be used for astronomical data denoising and deconvolution, when the data are contaminated by Gaussian and Poisson noise.

8858-20, Session 5

Spatio-spectral formulation and design of spatially varying filters for signal estimation on 2-Sphere

Zubair Khalid, Rodney A. Kennedy, Parastoo Sadeghi, Salman Durrani, The Australian National Univ. (Australia)

In this paper, we consider the problem of estimation of a non-stationary signal in the spatio-spectral domain, when the signal is subject to distortion and noise. The estimation of such signal in spatial or spectral domain is not adequate. By using the framework presented in the literature for signal transformation in the spatio-spectral domain, we develop optimal filter (signal estimator) in the spatio-spectral domain that deals with the non-stationarity of the signal. The spatio-spectral filtering is based on the spatially localized spherical harmonic transform (SLSHT) representation of a signal in the spatio-spectral domain. We then extend our spatio-spectral filter to develop weighted multiple window spatio-spectral filter, where different window functions are used for obtaining SLSHT representation of a signal. It is shown that the use of orthogonal windows obtained as eigenfunctions of the Slepian concentration problem on the sphere achieves good performance.

8858-21, Session 5

Classification and construction of closed-form kernels for signal representation on the 2-sphere

Rodney A. Kennedy, Parastoo Sadeghi, Zubair Khalid, The Australian National Univ. (Australia); Jason D. McEwen, Univ. College London (United Kingdom)

This paper considers the construction of reproducing kernel Hilbert Spaces~(RKHS) on the sphere as an alternative to the conventional Hilbert space using the inner product that yields the $L^2(S^2)$ function space of finite energy signals. In comparison with wavelet representations which have multi-resolution properties on $L^2(S^2)$, the representations that arise from the RKHS approach which uses different inner products have an overall smoothness constraint which may offer advantages and simplifications in certain contexts. The key contribution of this paper is to construct a classes of closed-form kernels, such as one based on the von-Mises Fisher distribution, which permits efficient inner product computation using kernel evaluations. Three cases of RKHS classes are defined: isotropic kernels and non-isotropic kernels both with spherical harmonic eigenfunctions, and general anisotropic kernels.

8858-22, Session 5

A spatiospectral localization approach for analyzing and representing vector-valued functions on spherical surfaces

Frederik J. Simons, Alain Plattner, Kevin W. Lewis, Princeton Univ. (United States)

In satellite geomagnetic research today, the data are vector-valued, collected at an altitude above the source, and their analysis and interpretation in terms of source models requires an often ill-conditioned inversion. Especially when the data are noisy and the area over which data are available, or over which information is being sought, is less than an entire sphere, proceeding by localization is a very fruitful approach. Scalar Slepian functions have been very successful at extracting spatiospectrally localized information from noisy data acquired by satellites, but until recently no framework existed for the treatment of vector fields. We have constructed vector-valued spherical basis functions, quadratically concentrated over arbitrary spatial domains, and illustrate their use for applications in satellite geomagnetism.

We are combining some recent, and some new results on vectorial localization on the sphere, with a special emphasis on harmonic fields for use in geomagnetism and related areas, e.g. medical imaging.

8858-23, Session 6

Combining multiple observations of audio signals

Ilker Bayram, Istanbul Technical Univ. (Turkey)

We consider the problem of reconstructing an audio signal from multiple observations, each of which is contaminated with time-varying noise. Assuming that the time-variation is different for each observation, we propose an estimation formulation that can adapt to these changes. Specifically, we postulate a parametric reconstruction and choose the parameters so that the reconstruction minimizes a cost function. Since the reconstruction is expected to be an audio signal, the cost function is selected so that audio signals are penalized less, compared to arbitrary signals with the same energy. As cost functions, we experiment with a recently proposed prior as well as mixed norms placed on the short time Fourier coefficients. Both of these cost functions allow to make use of the structured sparsity inherent in audio signals, in order to separate them from arbitrary signals. Thanks also to the special forms of these functions, we can express the estimation formulation as a saddle point problem. In order to solve the resulting saddle point problem, we employ recent algorithms proposed for such problems. As a further enhancement, we add regularization terms that apply directly on the parameters to be optimized. This direct regularization helps to incorporate known information about the noise terms, like smooth variation of their characteristics over time, leading to an improved reconstruction.

8858-24, Session 6

Hybrid approximate message passing methods for structured compressed sensing

Sundeep Rangan, Polytechnic Institute of New York Univ. (United States); Alyson K. Fletcher, Univ. of California, Santa Cruz (United States)

Approximate message passing (AMP) refers to a recently-developed class of graphical models-based algorithms for estimation of random, possibly non-Gaussian, vectors x from high-dimensional linear measurements. AMP methods have attracted considerable recent attention in the context of compressed sensing due to their computational simplicity, generality and analytic tractability. However, a key limitation of the AMP methodology is the requirement that the components of the vector x are independent, limiting the ability to incorporate other structural information in the prior on x that is critical in many practical compressed sensing problems. This paper presents a novel method called Hybrid Generalized AMP (HyGAMP) that extends the AMP methods to vectors x with priors described by general graphical models. The formulation can incorporate a wide class of structured sparse representations, including group sparsity and correlated sparsity modeled via general Markov random fields. Certain latent variables and hyper-parameters can also be incorporated into the model. The HyGAMP algorithm operates by representing the overall system as a larger graphical model partitioned into components with linear, dense dependencies along with stronger, possibly nonlinear, sparse relationships. Estimation is then performed by combining standard loopy belief propagation updates along the sparse, nonlinear, components of the graph with AMP-type updates in the dense, linear section.The formulation is extremely general and we demonstrate the effectiveness of the HyGAMP methodology in sparse multinomial regression problems as well as image denoising with multiple transforms.

8858-25, Session 6

On linear transform design with non-linear approximation

Osman G. Sezer, Texas Instruments Inc. (United States); Onur G. Guleryuz, FutureWei Technologies, Inc. (United States)

In this paper we share our recent observations on methods for sparsity enforced orthogonal transform design. In our previous work on this issue, our target was to design transforms that will minimize overall sparsity-distortion cost of a collection of image patches mainly for improving the performance of compression methods. In this paper we go one step further to understand why these transforms achieve better approximation and how different they are from transforms like the DCT or the Karhunen-Loeve transform (KLT). Our study lead us to mathematically validate that for a Gaussian process the KLT is the optimal transform not only in a lienar approximation sense but also in a nonlinear approximation sense, the latter forming the basis for sparsity-based regularization.

This means our transform design method yields the KLT in Gaussian processes, yet distinctly differentiates itself from the KLT in non-Gaussian cases by capturing useful structures within the data. Both toy examples and real compression results in various representation domains are presented in this paper to support our observations.

8858-26, Session 6

Group sparse optimization by alternating direction method

Wei Deng, Wotao Yin, Yin Zhang, Rice Univ. (United States)

Group sparsity is an emerging terminology that characterizes the underlying sparsity and structure of the data. Real-world data (such as audio signals, images and videos) is often highly sparse and richly structured. Group sparsity techniques, by taking advantage of the sparsity and structural information in the data, will facilitate more efficient ways to tackle large and complicated data in practice. We develop efficient algorithms for solving a class of optimization problems with group sparse solutions, which arise in various applications such as compressive sensing, statistics, signal and image processing, machine learning and computer vision. The mixed $L_{2,1}$-norm is used to promote group sparsity. But the resulting problems can be quite challenging to solve due to the nonsmoothness, mixed-norm structure and possible grouping irregularities. Our approach is based on a variable splitting strategy and the alternating direction methodology. The proposed algorithms are first-order methods, suitable for large-scale computation. The per-iteration computational cost is reasonably low, which is roughly two matrix-vector multiplications. Extensions of the algorithms can be easily made to enforce nonnegativity in the data and allow arbitrary grouping structures such as overlapping groups. The global convergence of our algorithms is guaranteed by the existing theory of the alternating direction method. We also extend the convergence theory to allow more generality and more options of solving the subproblems. Extensive numerical results are presented to demonstrate the efficiency, stability and robustness of the proposed algorithms, in comparison with the previously known state-of-the-art algorithms.

Randomized sampling in exploration seismology *(Keynote Presentation)*

Felix J. Herrmann, The Univ. of British Columbia (Canada)

No Abstract Available

8858-28, Session 8

A unified framework for 3rd generation lidar pulse processing based on finite rate of innovations

Charles D. Creusere, Juan Castorena, New Mexico State Univ. (United States)

In this paper, we will introduce a LIDAR return pulse analysis framework based on the concept of finite rate of innovations (FRI). Specifically, the proposed FRI-based model allows us to characterize the temporal return pulse envelopes captured by 3rd generation LIDAR systems in a low dimensional space. Furthermore, the extracted model parameters can be shown in many realistic scenarios to map to specific physical features of the scene being captured. After describing the model formulation and extraction process, we will illustrate its potential utility in two specific applications: sub-spot size ranging (super-resolution) and random impulsive scene sampling. Because of space limitations in this extended abstract, we will discuss only the pulse modeling aspect of our work here. In the actual paper, however, we will also present results illustrating the utility of our model for both random impulsive scene sampling and super-resolution.

8858-29, Session 8

MAP recovery of B-spline from compressive samples and its application to vehicular signals

Akira Hirabayashi, Yamaguchi Univ. (Japan); Satoshi Makido, Toyota Central R&D Lab. (Japan); Laurent Condat, Grenoble Institute of Technology (France)

We propose a stable reconstruction method for B-spline signals from compressive samples based on maximum a posteriori (MAP) estimation. The B-spline is one of the most powerful tools for modeling signals in real applications. Since such functions are not band-limited, the classical sampling theorem cannot be applied to them. However, splines can be regarded as signals with finite rate of innovation and therefore be perfectly reconstructed from noiseless samples acquired at, approximately, the rate of innovation. Our approach based on MAP estimation reconstructs the signals stably from noisy samples, more efficiently than the conventional methods that use the so-called annihilating filter. We show the effectiveness of our method by applying it to compressive sampling of vehicular signals.

8858-30, Session 8

Sampling great circles at their rate of innovation

Samuel Deslauriers-Gauthier, Pina Marziliano, Nanyang Technological Univ. (Singapore)

In our previous work, we extended signals that can be sampled and reconstructed at their rate of innovation to include Diracs defined on the sphere in 3D Euclidean space. Here, we show that great circles, the intersection of a plane through the origin and a sphere centered at the origin, can be reconstructed using similar methods. Specifically, we show that 2K(4K - 1) samples are sufficient to exactly recover K great circles. The sampling scheme involves a kernel defined on the 3D rotation group which allows us to recover a subset of the spherical harmonic coefficients of the great circles. We then show that the parameters of the great circles can be extracted from these coefficients. The performance of our method is illustrated using several numerical simulations.

8858-31, Session 8

3D imaging of simple scenes using parametric signal processing

Andrea Colaco, Ahmed Kirmani, Jonathan Mei, Nan-Wei Gong, Vivek K. Goyal, Massachusetts Institute of Technology (United States)

We introduce a new architecture for optical sensing of 3D structure of simple scenes that is based on parametric modeling and processing of scene impulse responses. In contrast to conventional techniques, this framework offers simplicity of hardware, high frame rates, compact form factors, insensitivity to ambient light, and low power. Our method is not intended for high spatial resolution 3D imaging of general scenes, but rather high accuracy localization and tracking of specific scene features. Simulations and initial hardware experiments demonstrate two potential applications: localization of two hands for a gestural interface and estimation of plane position and pose for augmented reality.

8858-32, Session 8

A sampling theorem for sparse signals on the sphere

Yue M. Lu, Harvard Univ. (United States)

Signals defined on the two dimensional sphere are encountered in many domains, including geophysics, astronomy, quantum chemistry, and spatial audio acquisition. We develop a novel sampling theorem for reconstructing K-sparse signals on the sphere from O(K^2) samples. The proposed reconstruction algorithm is computationally efficient. It is also shown to be robust in the presence of noise. Two applications are presented: 1. localizing diffusion sources using a small number of irregularly placed sensors; and 2. removing shot noise in the samples of bandlimited functions on the sphere.

8858-33, Session 8

Approximate Strang-Fix: sampling infinite streams of Diracs with any kernel

Pier Luigi Dragotti, Jon Onativia, Antonio Uriguen, Imperial College London (United Kingdom); Thierry Blu, The Chinese Univ. of Hong Kong (China)

In the last few years, several new methods have been developed for the sampling and the exact reconstruction of specific classes of non-

bandlimited signals known as signals with finite rate of innovation (FRI). This is achieved by using adequate sampling kernels and reconstruction schemes. An important class of kernels is the one made of functions able to reproduce exponentials.

In this paper we depart from the situation in which we can choose the sampling kernel and develop a new strategy that is universal in that it works with any kernel. We do so by noting that meeting the exact exponential reproduction condition is too stringent a constraint, we thus allow for a controlled error in the reproduction formula in order to use the exponential reproduction idea with any kernel and develop a reconstruction method which is more robust to noise.

Moreover we propose a novel method that is able to reconstruct infinite streams of Diracs, even in high noise scenarios. We sequentially process the discrete samples and output locations and amplitudes of the Diracs in real-time. We first establish conditions for perfect reconstruction in the noiseless case and then present the sequential algorithm for the noisy scenario. We also show that we can achieve a high reconstruction accuracy of 1000 Diracs for SNRs as low as 5dB.

8858-35, Session 9

Joint image registration and reconstruction from compressed multi-view measurements

Gilles Puy, Pierre Vandergheynst, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

We present a method for joint reconstruction of a set of images, representing a same scene, from few linear multi-view measurements. We model the correlation between the measurements using geometric transformations represented by few parameters. The proposed method estimates both these parameters and the observed images using the measurements as the sole information. It is also robust to occlusions. The reconstruction algorithm minimizes a non-convex functional and generates a sequence of estimates converging to a critical point of this functional. We show the efficiency of the algorithm in compressed sensing applications.

8858-36, Session 9

Real-time compressive video using coded aperture cameras

Thomas A. Goldstein, Richard G. Baraniuk, Rice Univ. (United States)

Single-pixel cameras" are a new modality for image acquisition using compressive measurements. In contrast to conventional imaging, which relies on arrays of many photodetectors, single picture cameras obtain high resolution images using only a single detector. This is accomplished using a "coded aperture," which compresses global image information into each measurement rather than observing one pixel at a time. In this talk, we discuss the challenges of applying these new compressive imaging tools to video acquisition. Compressive video poses many challenges that imaging does not. We are no longer imaging a static scene, but rather we must explicitly model the motion of objects and exploit correlations between adjacent frames. Furthermore, real-time reconstruction of video from compressive measurements requires the use of sophisticated numerical algorithms and parallel hardware implementations.

8858-37, Session 9

Sparsity and cosmology: inverse problems in cosmic microwave background experiments

Florent Sureau, Jérome Bobin, Jean-Luc Starck, Commissariat à l'Énergie Atomique (France)

Full-sky Cosmic Microwave Background (CMB) missions such as Planck or WMAP aims at providing key information about the structure and evolution of our universe as well as breakthroughs in the knowledge of the interstellar medium and extra-galactic emissions.These objectives are challenged by the mixing in between the CMB and these various components in the observed multichannel data. In this presentation, we will illustrate how the sparsity of the components can be used in various inverse problems in component separation and restoration, and how these problems can be solved based on recent works in optimization theory.

8858-39, Session 9

Optimal wavelet decomposition of sparse stochastic processes

Michael Unser, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Sparse stochastic processes are continuous-domain processes that admit a parsimonious representation in some matched wavelet-like basis. Such models are relevant for image compression, compressed sensing, and, more generally, for the derivation of statistical algorithms for solving ill-posed inverse problems.

In this presentation we shall provide theoretical evidence that Haar wavelets are optimal for the representation of certain non-Gaussian brands of Lévy processes and that they outperform the Karhunen-Loève transform.

8858-40, Session 10

Coding and sampling for compressive x-ray tomography

David J. Brady, Duke Univ. (United States)

Coded apertures and energy resolving detectors may be used to improve the sampling efficiency of x-ray tomography and increase the physical diversity of x-ray phenomena measured. Coding and decompressive inference enable increased molecular specificity, reduced exposure and reduced scan times.

8858-41, Session 10

Compressive sensing with quadratic phase systems and examples in optics

Adrian Stern, Yair Rivenson, Ben-Gurion Univ. of the Negev (Israel)

Spatial and temporal quadratic phase filters represent the behavior of many processes in various fields (e.g. optical, radar, sonar etc.) and applications. Here we examine the applicability of QPS as compressive sensing operators. Compressive sensing is a joint signal acquisition-reconstruction paradigm, which has gained much attention recently since it provides a framework for the reconstruction of highly subsampled signals. Convolution with quadratic phase kernels represents many spatial and temporal systems. This, together with the fact that under certain conditions quadratic phase filters (QPF) share similar features to Fourier transform operator, makes them an attractive choice for compressive sensing implementation. It is shown that CS performance of quadratic phase systems depends on the specific implementation parameters such as sampling intervals and quadratic phase filter parameter. For example, in the case that the QPF represents optical field propagation, it is shown that in the near field regime the number of measurements needed to fully reconstruct an object is proportional to the object's Fresnel number, while in the far field the number of measurements is in the order of the signal's sparsity level times a log factor.

The fact that QPF exhibit efficient CS behavior has been utilized for systems involving sparse aperture and sparse detector arrays, imaging behind partially opaque media and 3D object reconstructed from propagated fields. It has also been proved useful for tomography of three dimensional objects from a single two dimensional projection. This problem is highly ill-posed. We discuss the conditions for the solution of such problem and show its relation with the physical quantities of the object and of the detector.

8858-42, Session 10

Lens-free computational microscopy

Aydogan Ozcan, Univ. of California, Los Angeles (United States)

Today there are around 6 billion cell-phone users in the world, and the majority of these cellphones are being used in the developing parts of the world. This massive volume of wireless phone communication brings an enormous cost-reduction to cellphones despite their sophisticated hardware and software capabilities. Utilizing this advanced state of the art of the cell phone technology towards point-of-care diagnostics and/or microscopic imaging applications can offer numerous opportunities to improve health care especially in the developing world where medical facilities and infrastructure are extremely limited or even do not exist.

Centered on this vision, in this talk I will introduce new imaging and detection architectures that can compensate in the digital domain for the lack of complexity of optical components by use of novel theories and numerical algorithms to address the immediate needs and requirements of Telemedicine for Global Health Problems. Specifically, I will present an on-chip cytometry and microscopy platform that utilizes cost-effective and compact components to enable digital recognition and 3D microscopic imaging of cells with sub-cellular resolution over a large field of view without the need for any lenses, bulky optical components or coherent sources such as lasers. This incoherent holographic imaging and diagnostic modality has orders of magnitude improved light collection efficiency and is robust to misalignments which eliminates potential imaging artifacts or the need for realignment, making it highly suitable for field use. Applications of this lensfree on-chip microscopy platform to high-throughput imaging and automated counting of whole blood cells, monitoring of HIV+ patients (through CD4 and CD8 T cell counting) and detection of waterborne parasites towards rapid screening of water quality will also be demonstrated. Further, I will discuss lensfree implementations of various other computational imaging modalities on the same platform such as pixel super-resolution imaging, lensfree on-chip tomography, holographic opto-fluidic microscopy/tomography. Finally, I will demonstrate lensfree on-chip imaging of fluorescently labeled cells over an ultra wide field of view of >8 cm2, which could be especially important for rare cell analysis (e.g., detection of circulating tumor cells), as well as for high-throughput screening of DNA/protein micro-arrays.

8858-43, Session 11

Rotation-covariant visual concept detection using steerable Riesz wavelets and bags of visual words

Adrien Depeursinge, Stanford Univ. (United States) and Univ. & Univ. Hospitals of Geneva (HUG) (Switzerland) and Univ. of Applied Sciences Western Switzerland (Switzerland); Antonio Foncubierta-Rodriguez, Univ. of Applied Sciences Western Switzerland (HES–SO) (Switzerland); Henning Müller, Univ. of Applied Sciences Western Switzerland (HES–SO) (Switzerland) and Univ. & Univ. Hospitals of Geneva (HUG) (Switzerland); Dimitri Van de Ville, Ecole Polytechnique Fédérale de Lausanne (Switzerland) and Univ. & Univ. Hospitals of Geneva (HUG) (Switzerland)

Distinct texture classes are often sharing several visual concepts. Texture instances from different classes are sharing regions in the feature hyperspace, which results in ill-defined classification configurations. In this work, we detect rotation-covariant visual concepts using steerable Riesz wavelets and bags of visual words. In a first step, k-means clustering is used to detect visual concepts in the hyperspace of the energies of multiscale N-th order Riesz wavelets. The coordinates of the clusters are used to define linear combinations of the Riesz templates that are corresponding to visual concepts. The visualization of these feature signatures allows verifying the relevance of the concepts modeled. Then, the local orientations of each signature are optimized to maximize their response, which is carried out analytically and can still be expressed as a linear combination of the initial steerable Riesz templates. The texture classes are learned in the feature space composed of the concatenation of the maximum responses of each signature using support vector machines. An experimental evaluation using the Outex_TC_00010 test suite demonstrates the feasibility of the proposed approach. A sufficient number k of clusters is required to model the visual concepts. The importance of rotation-covariance is highlighted using the response of the initial templates for classification.

8858-44, Session 11

Time-frequency, frequency coupling, and electroencephalography signals

Sofia C. Olhede, Univ. College London (United Kingdom)

Time-frequency, frequency coupling, and EEG Signals joint work with Maria Fitzgerald and Hernando Ombao

Electroencephalography signals contain a wealth of structure. This can take the form of complicated and patterned time-frequency structure. We shall discuss two special examples and methods for their understanding; namely the development of analysis methods for EEG from prematurely born infants and the formation of their pain perception, as well as adult EEG signals. Models will be built both in frequency; describing the coupling of complicated frequency behaviours, as well as of temporally localized characteristics.

8858-45, Session 11

Video sampling and reconstruction: a comparison of compressed sensing and phase retrieval reconstruction methods

Yoann Le Montagner, Institut Pasteur (France) and Telecom ParisTech (France); Elsa D. Angelini, Telecom ParisTech (France); Jean-Christophe Olivo-Marin, Institut Pasteur (France)

The theory of compressed sensing (CS) predicts that structured images can be sampled in a compressive manner with very few non-adaptive linear measurements, made in a proper adjacent domain. Here, we investigate the problem of recovering a video signal from a subset of Fourier modulus -- therefore non-linear -- samples, taking advantage of some relevant sparse prior assumptions on the signal of interest. We compare this recovery technique to the usual convex reconstruction method encountered when dealing with linear CS measurements. We present some simulation results obtained on real video sequences coming from biological imaging experiments.

8858-46, Session 11

A fast thresholded multi-channel Landweber algorithm for wavelet-regularized multi-angle deconvolution

Nikhil Chacko, Michael Liebling, Univ. of California, Santa Barbara (United States)

3D deconvolution in optical widefield microscopy aims at recovering optical sections through thick objects. Acquiring data from multiple, mutually-tilted directions helps fill the missing cone of information in the optical transfer function, which normally renders the deconvolution problem particularly ill-posed. Here, we propose a fast-converging iterative deconvolution method for multi-angle deconvolution microscopy. Specifically, we formulate the imaging problem using a filter-bank structure, and present a multi-channel variation of a thresholded Landweber deconvolution algorithm with wavelet-sparsity regularization. Decomposition of the minimization problem into subband-dependent terms ensures fast convergence. We demonstrate the applicability of the algorithm via simulation results.

8858-47, Session 12

Decoding bits from photons on the fly: online image formation for spatiotemporal single-photon imaging

Yue M. Lu, Harvard Univ. (United States)

Resolving individual photons in space and time is the holy grail of optical imaging. In recent years, there have been increasing efforts to develop solid-state sensors with single-photon sensitivity. From a signal processing perspective, it is natural to consider these sensors as spatiotemporal sampling devices of the incident light intensity field. The unknown light field can be reconstructed from the sensor measurements by maximum likelihood estimation. Unlike our previous work where the image formation is done offline, we develop a new online image formation algorithm based on stochastic approximations, which can “decode” the bitstreams from the single-photon sensors in real time. We establish the consistency and convergence rate of the proposed recursive estimation scheme.

8858-48, Session 12

Compressed gated range sensing

Grigorios Tsagkatakis, Foundation for Research and Technology-Hellas (Greece); Arnaud Woiselle, Sagem Défense Sécurité (France); George Tzagkarakis, Commissariat à l’Énergie Atomique (France); Marc Bousquet, Sagem Défense Sécurité (France); Jean Luc Starck, Commissariat à l’Énergie Atomique (France); Panagiotis Tsakalides, Foundation for Research and Technology-Hellas (Greece)

Active Range Gated imaging systems employ an active illumination source, usually a laser, and a camera system in order to generate a 2D depth map. Extracting the 2D depth image of a scene is traditionally achieved by either recording a large number of frames, proportional to the requested depth resolution or by utilizing a pattern for the opening and closing of the gates such that efficient encoding of the signals is achieved. In this work, we propose a CS based sampling and reconstruction approach that requires far less samples while being more robust to environmental effects. Assuming a single laser pulse is reflected by an object, CS based sampling amounts to obtaining measurements via a measurements matrix that encodes the random gating function for every frame and must satisfy the RIP property. In order to introduce prior information into the signal characteristics, such as the power drop caused by the distance, an appropriate dictionary is constructed capturing properties such as depth dependencies and backscatter. As a result, the requested vector will be sparse and will only encode the depth information. Reconstruction of the depth signal is obtained by an l¬1 norm minimization. In order to obtain a realistic performance evaluation, special care is given to the modeling of the system. The depth signals are modeled as delta functions at specific time instances, while the interaction between the photons and the molecules in the atmosphere as well as atmospheric absorption and beam divergence are also modeled.

8858-49, Session 12

Angle-preserving quantized phase embeddings

Petros T. Boufounos, Mitsubishi Electric Research Labs. (United States)

The phase of randomized complex-valued projections of real signals preserves information about the angle, i.e., the correlation, between signals. This information can be exploited to design quantized angle-preserving embeddings, which represent such correlations using a finite bit-rate. These embeddings generalize known results on binary embeddings and 1-bit compressive sensing and reduce the embedding uncertainty given the bit-rate.

8858-50, Session 12

Poisson noise removal with pyramidal multi-scale transforms

Arnaud Woiselle, Sagem Défense Sécurité (France); Jean-Luc Starck, Commissariat à l’Énergie Atomique (France); Jalal M. Fadili, ENSICAEN (France)

In this paper, we introduce a new method to stabilize the variance of multi-scale (MS) decimated transforms. We first use this method to the adaptation of the 3D BeamCurvelet transform to data corrupted with Poisson noise, then demonstrate its efficiency by applying the proposed multi-scale variance stabilizing transform (MS-VST) to the denoising of a simulated cosmological volume.

The MS-VST introduced by Zhang [Anscombe 1948, zhang 2008], stabilizes the variance of the low-pass filtered versions of a signal, and builds the stabilized detailed bands by differences of these scales. This implies that the scales must all have the same size, and can only be applied to undecimated trnsforms. In order to generalize this approach to a wider range of multi-scale representations, we introduce two different yet similar variance stabilizing operators that work respectively in the decimated and undecimated spaces. Then we use them on the low-pass scales of a 3D Meyer wavelet transform, in its pyramidal - hence decimated - form, which is at the core of the BeamCurvelets.

The proposed variance stabilized BeamCurvelets are used to recover the underlying density of a simulated dark matter cosmological volume with low and very low count-rate. This transform is well adapted to the filamentary structure of this kind of data. The results are compared to stabilized isotropic undecimated wavelets, and un-stabilized BeamCurvelets, and finally the stabilized BeamCurvelets are combined with the stabilized wavelets to take advantage of their morphological diversity and get even better results.

8858-51, Session 12

Compressed sensing image construction for the LOFAR Radio Telescope

Hugh Garsden, Jean-Luc Starck, Stéphane Corbel, Commissariat à l’Énergie Atomique (France); Cyril Tasse, SKA South Africa (South Africa)

Traditionally, the CLEAN method has been used to produce images from radio interferometry data.

Compressed Sensing is a promising alternative, and we have implemented it in the software that generates images for the LOFAR Radio Telescope in Europe. I will explain how compressed sensing differs from CLEAN, and the details and issues of implementing compressed sensing for real radio telescope data. Statistical and visual results of image generation using compressed sensing will be shown, and compared to CLEAN. Based on these, future work will be listed and discussed, including implementation plans, testing, efficacy, and use by astronomers in the field.

8858-52, Session 12

Spatio-temporal regularization for combined range and reflectance imaging with high photon efficiency

Ahmed Kirmani, Andrea Colaco, Dongeek Shin, Vivek K. Goyal, Massachusetts Institute of Technology (United States)

Conventional cameras for ordinary photography and for ranging by time-of-flight methods use thousands to millions of detected photons per pixel to form images. Through spatio-temporal regularization achieved with MAP estimation under a wavelet-domain sparsity prior and an inhomogenous Poisson-process likelihood function, we form images with dramatically higher photon efficiency—even as low as one detected photon per pixel. We demonstrate this 1 photon-per-pixel photon efficiency along with sub-pulse-width range resolution in megapixel laser range imaging with practical equipment, and we show the improvement of our integrated processing over post facto denoising.

8858-53, Session 12

Compressive sensing in signal and sampling for MIMO radar

Juan Lopez, Zhijun Qiao, The Univ. of Texas-Pan American (United States)

MIMO radar utilizes the transmission and reflection of multiple independent waveforms to construct an image approximating a target scene. Compressed sensing (CS) techniques such as total variation (TV) minimization and greedy algorithms can permit accurate reconstructions of the target scenes from undersampled data. The success of these CS techniques is largely dependent on the structure of the measurement matrix. A discretized inverse scattering model is used to examine the imaging problem, and in this context the measurement matrix consists of array parameters regarding the geometry of the transmitting and receiving arrays, signal type, and sampling rate. We derive some conditions on these parameters that guarantee the success of these CS reconstruction algorithms. The effect of scene sparsity on reconstruction accuracy is also addressed. Numerical simulations illustrate the success of reconstruction when the array and sampling conditions are satisfied, and we also illustrate erroneous reconstructions when the conditions are not satisfied.

8858-77, Session PWed

Imaging dark matter using sparsity

Francois Lanusse, Adrienne Leonard, Jean-Luc Starck, Commissariat à l'Énergie Atomique (France)

By its very nature dark matter cannot be directly observed and only through its gravitational effects can it be studied. In particular, the study of the small deformations of the shapes of background galaxies due to the presence of dark matter, known as weak lensing effect, has received a lot of attention over the past decade and is at the heart of the future ESA mission Euclid. When the distances and shapes of a large number of galaxies can be measured, the problem of reconstructing a 3D dark matter map can be addressed. However, weak lensing is an integrated effect along the line of sight and recovering the radial position of dark matter halos involves deprojecting the lensing signal from a limited number of noisy galaxy shape and distance measurements. Considering that the 3D dark matter density is sparse in an appropriate wavelet based 3D dictionary, this problem can be seen as an instance of Compressed Sensing and the recovery of a 3D map becomes possible using sparsity regularized inversion techniques. We propose an iterative soft thresholding algorithm to solve a penalized least-squares problem. We present our results on simulated dark matter halos and compare them to existing reconstruction techniques. We show that thanks to our 3D sparsity constraint the quality of the reconstructed maps can be greatly improved.

8858-78, Session PWed

Curvelet-based method for orientation estimation of particles

Jouni J. Takalo, Univ. of Jyväskylä (Finland); Jouni A. Sampo, Lappeenranta Univ. of Technology (Finland); Jussi Timonen, Univ. of Jyväskylä (Finland); Samuli Siltanen, Matti Lassas, Univ. of Helsinki (Finland)

A new method based on the curvelet transform is introduced here for estimating the orientation distribution in two-dimensional images of elongated features (particles). Theoretical aspects of the suitability of this method are discussed and its efficiency is demonstrated with simulated and real images of fibrous systems.

The estimate by this method for an image of known features was demonstrated to be very accurate, and to clearly outperform those by the FFT and structure tensor (ST) methods used here to represent traditional orientation-analysis methods. There was also strong indication that the results of curvelet-based method for images of newsprint and organic nanofibrils were more reliable than the corresponding FFT and ST results.

The curvelet analysis of an image can be made very fast: we estimated and partly demonstrated that such analysis can be implemented so that it only takes few milliseconds. This would allow on-line analysis with about 20 micrometer resolution in a paper machine with a web speed of 20 m/s. It is also evident based on the results reported here that the curvelet method is robust and rather insensitive to noise in the image. This property strengthens its usability in practical applications.

8858-79, Session PWed

Optical coherence tomography noise reduction over learned dictionaries with introduction of complex wavelet for start dictionary

Raheleh Kafieh, Hossein Rabbani, Isfahan Univ. of Medical Sciences (Iran, Islamic Republic of)

Optical coherence tomography (OCT) is a recently established imaging technique to describe different information about the internal structures of an object. The performance of this method is principally similar to ultrasound imaging, except that OCT uses light beams instead of sound profiles. OCT has made its most significant clinical contribution in the field of ophthalmology, where it has become a key diagnostic technology in the areas of retinal diseases and glaucoma. Similar to ultrasound images, OCT suffers from speckle noise which causes erroneous interpretation. In this work, we discuss on application of denoising methods based on dictionary learning. It is not computationally efficient to apply K-SVD on the whole image. Therefore, overlapping patches should be obtained from the original data and a dictionary D can be learned on these patches by the K-SVD algorithm. In this paper we compare conventional (2D-CDL) and double-sparse dictionary learning (2D-DSDL) methods for OCT denoising. We also use 3D dictionary learning method in double-sparse dictionary learning (3D DSDL) and show their superiority on 2D versions. The start dictionary in K-SVD algorithm was redundant DCT, but since the proposed penalty term is a highly non-convex functional, local minimum solutions are likely to happen. Thus, a wise initialization could improve the results of conventional algorithms. In our experiments we started with complex wavelet dictionaries for their shift invariant and directionally selective characteristics, along with overcomplete subband decomposition (2D-CWDL and 3D-CWDL).

8858-80, Session PWed

Dense grid sibling frames with linear phase filters

Farras Abdelnour, Weill Cornell Medical College (United States)

We propose new dyadic sibling frames (dual frames sharing the same lowpass filter) dyadic with dense time-frequency grid. The resulting limit functions are smooth with higher approximation order. The proposed frame feature redundant highpass filters which are identical within one sample shift.

This leads to wavelets approximating shift-invariance. The filters are FIR and have vanishing moments.

The filters' design steps are simple and use spectral factorization methods. Enhanced denoising performance has been obtained using redundant wavelets (frames). Additionally, sibling frame wavelets lead to smooth limit functions and computationally stable implementation. In this paper we design 5-channel sibling-frame symmetric filterbank ${h_0,h_1,h_2,h_3,h_4 }$ and using ${g_0,g_1,g_2,g_3,g_4 }$

spectral factorization methods. The resulting filters have linear phase and smooth limit functions.

8858-54, Session 13

Hub screening on brain graphs

Alfred O. Hero, Hamed Firouzi, Univ. of Michigan (United States)

``Connectomes" or Brain Graphs have become a very popular way of representing the neurodata. Recent studies show the existence of highly connected hubs in the brain graphs. Motivated by this fact, we apply the existing theory of correlation screening to discover the correlations in brain graphs. We assign a feature vector of hub p-values to a brain graph. The proposed feature vector enables a computationally efficient classifier for healthy versus patient classification. The efficiency of the proposed method is shown by performing experiments on a fMRI dataset.

8858-55, Session 13

Fast algorithms for multiscale analysis on graphs

Mauro Maggioni, Duke Univ. (United States)

We present a novel approach to construct multiscale dictionaries on graphs, which generalize wavelets to these spaces. The elements of these bases and frames are localized in space and frequency in a way analogous to classical wavelets, but where space is given by a graph and frequency is determined by the spectral representations associated with the Laplacian on a graph. The construction of these bases is accomplished by fast algorithms, and the transforms, both forward and backward, are fast as well.

We then discuss applications to compression of functions on graphs, and to regression and machine learning tasks on graphs.

8858-56, Session 13

Iterated two-channel filterbanks on undirected graphs

Akshay Gadde, Sunil K. Narang, Antonio Ortega, The Univ. of Southern California (United States)

In this paper, we propose the construction of iterative two channel wavelet filterbanks on any arbitrary undirected weighted graph. The proposed two-channel filterbanks provide a multiresolution decomposition of any graph signal into succesive lowpass and highpass signals. This work stems from our previous work on the design of critically sampled two-channel filterbanks on bipartite graphs. We use recent results from the theory of sampling bandlimited signals on graphs, which allow us to downsample the output of each channel in two-channel filterbank on a subset of vertices without loss. We describe the properties of these downsampling sets, and the resulting iterated construction of two-channel filterbanks.

8858-57, Session 13

On the interplay between topology and signals supported on graphs

Michael Rabbat, McGill Univ. (Canada)

Recent work has begun to develop a theory for the representation, processing, and approximation of signals supported on graphs. For signals supported on graphs, the eigenvectors of the graph Laplacian play a role analogous to the Fourier transform. We discuss recent results which develop uncertainty principles for signals supported on graphs, focusing on the role of the graph topology. Characteristics of the graph topology which are captured by the Laplacian spectrum and relate to notions of smoothness with respect to signals supported on the graph. We leverage these observations in an algorithm for fitting a graph to data.

8858-58, Session 13

On the sparsity of wavelet coefficients for signals on graphs

David I. Shuman, Benjamin Ricaud, Pierre Vandergheynst, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Over the past decade, a number of new localized, multiscale transforms have been introduced to analyze data residing on weighted graphs. In signal processing tasks such as regularization and compression, much of the power of "classical" wavelets on the real line is derived from their theoretically and empirically proven ability to sparsely represent piecewise-smooth signals, which appear to be locally polynomial at sufficiently small scales. As of yet in the graph setting, there is little mathematical theory relating the sparsity of localized, multiscale transform coefficients to the structures of graph signals and their underlying graphs. In this talk, we begin to empirically and theoretically investigate the question of which classes of signals on graphs are sparsely represented by different localized, multiscale transforms.

8858-59, Session 13

Anomalous cluster detection

Venkatesh Saligrama, Jing Qian, Boston Univ. (United States)

We are interested in deciding whether or not a cluster of nodes, forming a connected component on a graph, exhibit abnormal behavior. The nodes of the graph have random variables associated with them which are i.i.d standard normal under null hypothesis.Under the alternative, the variables of nodes of the anomalous cluster are i.i.d normal with some positive mean and unit variance. The set of arbitrary-shaped connected sub-graphs of a graph is too large for the well-known optimal scan statistic method to apply directly. We present a novel optimization framework that imposes smoothness of graph structures on the scanned cluster of nodes based on the scan statistic method. Specifically, we propose to tradeoff maximizing the scan statistic with minimizing a graph-cut term, which intuitively acts like doing a graph partitioning between the anomalous and normal nodes.

We then provide a model selection framework that allows to choose the cluster with maximum scan statistic value while being connected. Experiments demonstrate the ability of our method to detect arbitrary-shaped connected anomalous clusters on graphs.

8858-60, Session 13

Detecting subgraph structure of a linear dynamical system

Ameya Agaskar, Harvard Univ. (United States) and MIT Lincoln Lab. (United States); Yue M. Lu, Harvard Univ. (United States)

We consider the problem of detecting hidden graph structure underlying a discrete-time linear dynamical system from only a small set of measurements. We assume that the state space consists of two types of nodes: graph nodes, which obey an autoregressive model driven by Gaussian noise and whose dynamics are determined by an unknown weighted adjacency matrix, and nuisance nodes, whose states are just noise. Our observations are linear combinations of all the nodes' states, determined by an observation matrix that we choose, and further corrupted with measurement noise. We assume that the graph nodes are far outnumbered by the nuisance nodes, and that the number of measurements is limited.

When the observation time is infinite, the graph nodes can be detected and their adjacency matrix reconstructed from the autocovariance computed from the observations. Only the zero- and one-lag covariance matrices are needed. The nullspace of the zero-lag covariance matrix consists of vectors whose support is entirely on the nuisance nodes; by examining these vectors, we can detect the graph nodes. Meanwhile, the adjacency matrix's eigenvalues are the generalized eigenvalues of a matrix pencil formed from these two matrices, and its eigenvectors can be reconstructed from the pencil's generalized eigenvectors. In practice, the observation time is finite and there are errors in estimating the autocovariance matrices. We use results from random matrix theory to determine conditions under which the graph nodes can be effectively distinguished from the nuisance nodes and the bound the error in the estimate of the adjacency matrix.

8858-61, Session 14

Near-optimal phase retrieval of sparse vectors

Afonso S. Bandeira, Princeton Univ. (United States); Dustin G. Mixon, Air Force Institute of Technology (United States); Boris Alexeev, Princeton Univ. (United States)

In many areas of imaging science, it is difficult to measure the phase of linear measurements. As such, one often wishes to reconstruct a signal from intensity measurements, that is, perform phase retrieval.

In several applications the signal in question is believed to be sparse. In this paper, we use ideas from the recently developed polarization method for phase retrieval and provide an algorithm that is guaranteed to recover a sparse signal from a number of phaseless linear measurements that scales linearly with the sparsity of the signal (up to logarithmic factors). This is particularly remarkable since it is known that a certain popular class of convex methods is not able to perform recovery unless the number of measurements scales with the square of the sparsity of the signal.

8858-62, Session 14

Sparsity and compressive sensing with parametric dictionaries

Dian Mo, Marco F. Duarte, Univ. of Massachusetts Amherst (United States)

We discuss the use of sparsity in parametric dictionaries for the purposes of parameter estimation. Common applications include localization and bearing estimation. We also consider the use of such dictionaries in compressive sensing and study sparse recovery algorithms and performance metrics that are tailored to specific applications.

8858-63, Session 14

Equiangular tight frames whose entries are pth roots of unity for small p

John D. Jasper, Univ. of Missouri (United States)

This paper is invited to the Peter Casazza session. In this talk we will present some methods for constructing equiangular tight frames whose entries are pth roots of unity for small p. In particular, we will present an infinite family of equiangular tight frames with all entries in {+1,-1}.

8858-64, Session 14

Frame theory for locally compact abelian groups

Emily J. King, Technische Univ. Berlin (Germany)

Analysis on locally compact abelian groups and local fields has applications in a variety of different fields. Traditional Fourier analysis is based on the characters of R^n, T^n, and Z^n. There is a growing body of literature using functions on p-adic groups to model quantum phenomena, and p-adic wavelets diagonalize certain important pseudo-differential operators. Fourier analysis on local fields comes up class field theory and in the study of particular zeta functions. Piecemeal approaches to classifying shift-invariant spaces and other systems generated by group actions on locally compact abelian groups exist, but a uniform treatment does not yet exist. This talk will present new results in this area.

8858-65, Session 14

Fast null space tuning algorithms with feedbacks for sparse signal recovery

Tiebin Mi, Renmin Univ. of China (China); Shidong Li, San Francisco State Univ. (United States)

We provide another framework of fast iterative algorithms based on null space tuning, thresholding, and feedbacks for sparse signal recovery arising in sparse representation and compressed sensing. Several algorithms with different feedbacks are derived, which are seen as exceedingly effective and fast. Convergence results are also provided. The core algorithm is shown to converge in finite many steps under a (preconditioned) restricted isometry condition. Numerical studies about the effectiveness and the speed of the algorithms are also presented. The algorithms are seen as particularly effective for large scale problems.

8858-66, Session 15

Multiscale dictionaries, transforms, and learning in high-dimensions

Mauro Maggioni, Duke Univ. (United States)

We introduce multiscale constructions for the estimation of the intrinsic dimension of noisy data, the construction of data-driven dictionaries for efficient sparse representations data sets and a novel geometric multiresolution analysis framework for encoding data. Finally we discuss the problem of estimating a probability measure in high dimensions, whose support is (nearly) low-dimensional and has some geometric structure, for example that of a manifold, or a union of hyperplanes. We construct a multiscale geometric tree decomposition of the data and use this decomposition to construct an increasing family of approximation "spaces" in the space or probability measures, parametrized by certain subtrees of the multiscale tree, and perform a multiscale bias-variance tradeoff using this family of approximation spaces. We obtain finite-sample results that guarantee that with high probability the Wasserstein distance between the (random) measure estimated by our algorithm and the true measure is small, depending on the number of samples, a measure of complexity of the models we use (typically this depends only on the intrinsic dimension and not on the ambient dimension!), and a notion of "regularity" of the true measure.

8858-67, Session 15

Random encoding of quantized finite frame expansions

Rayan Saab, Mark Iwen, Duke Univ. (United States)

We address the problem of encoding the bit-stream associated with quantized frame expansions. It has been previously shown that for a wide variety of finite frames, Sigma-Delta quantization achieves much better error decay as a function of the number of frame vectors than simple scalar quantization does. Nevertheless, the known error rates are not optimal. In this talk, we show that there exists a simple, random encoding algorithm acting on Sigma-Delta quantized finite frame expansions which --in conjunction with an associated linear decoding algorithm-- yields an approximation error that decays exponentially in the number of bits used. This result is near optimal, up to constants, and holds for a large family of frames.

More specifically, the proposed encoding strategy consists of applying a discrete random operator to the Sigma-Delta bit stream and assigning a binary codeword to the result. The reconstruction procedure, as previously mentioned, is essentially linear and equivalent to solving a least squares minimization problem. The proof of exponential error decay relies on concentration of measure techniques, subject to the frame at hand satisfying certain properties. In particular, smooth frames and random frames whose elements are sub-Gaussian random variables satisfy these properties.

8858-68, Session 15

Minimal frames for phase retrieval

Yang Wang, Michigan State Univ. (United States)

The classical phase retrieval problem concerns the reconstruction of a function from the magnitude of its Fourier transform. The more general version of it asks whether and how can one reconstruct a signal from the magnitudes of samples of the signal. In this talk we consider various minimality problems on frames with the phase retrieval property. For example, what is the minimal number of vectors needed in a frame to have the phrase retrieval property? For complex frames this question remains one of the main unsolved problems in phrase retrieval. But there are many other such problems. The main goal of this talk is a survey of the latest advances in this area.

8858-69, Session 15

Real phase retrieval by projections

Jameson Cahill, Peter G. Casazza, Jesse Peterson, Lindsey M. Woodland, Univ. of Missouri-Columbia (United States)

Frame theory has broad application today to a wide range of research topics. Integer frames are frames for which all of the entries with respect to a fixed orthonormal basis are integers. Integer frames give promise for reducing calculation times as well as reducing quantization errors. In this paper we make the first detailed study of real integer frames. We will see that equal norm or tight integer frames with N-elements are easy to construct for all M-dimensional Hilbert spaces. We then concentrate on equal norm tight integer frames. We will see that in some cases they cannot exist, such as any odd number of vectors in 2 dimensions. We will also see cases where they exist for all large number of vectors in certain dimensions and we look at some general classes where they exist.

8858-70, Session 16

Reconstruction with diffeomorphic motion compensation for undersampled dynamic MRI

Ganesh Adluru, Edward V. R. DiBella, The Univ. of Utah (United States)

We propose a compressed sensing type of reconstruction method that can handle large amounts of inter-frame motion by including diffeomorphic model-based registration steps within the iterative reconstruction. The method is ideal for speeding up respiratory-navigated late gadolinium enhancement images of the left atrium. It is also suitable for application to a newly proposed type of myocardial perfusion imaging that does not use ECG gating. Such an acquisition is a simpler alternative to conventional ECG gated acquisitions but requires severe undersampling of k-space data and more sophisticated reconstruction methods. The new methods and preliminary results will be presented.

8858-71, Session 16

Motion estimation/compensated compressed sensing using patch-based low rank penalty

Huisu Yoon, Jong Chul Ye, KAIST (Korea, Republic of)

In this paper, a novel patch-based signal processing algorithm for motion estimated/compensated compressed sensing dynamic MR imaging that overcomes the limitation of the existing k-t FOCUSS with ME/MC. More specifically, we impose a non-convex patch-based low-rank penalty that exploits self-similarities within the images. This penalty is shown to favor capturing geometric features such as edges rather than reconstructing the background noises. To solve the resulting non-convex optimization problem, we propose a globally convergent concave-convex procedure (CCCP) using convex conjugate, which has closed form solution at each sub-iteration. Experimental results demonstrate that the proposed algorithm outperforms the existing ones.

8858-72, Session 16

Low-rank and sparse matrix decomposition for accelerated dynamic MRI

Ricardo Otazo, Daniel K. Sodickson, New York Univ. Langone Medical Ctr. (United States); Emmanuel J. Candes, Stanford Univ. (United States)

This paper is invited to Dr. Mathews Jacobs session. Low-rank and sparse matrix decomposition (L+S) is proposed in the spirit of compressed sensing to reconstruct undersampled dynamic MRI data sets with separation of background (low-rank) and dynamic (sparse) components. The technique effectively suppresses the background before enforcing sparsity, which improves reconstruction performance, since the remaining images are sparser. In addition to increasing the acceleration capability of dynamic MRI in general, the ability to suppress the background without parametric modeling or image subtraction may be useful for several contrast-enhanced studies. Feasibility of the L+S method is demonstrated on cardiac cine and perfusion data sets and time-resolved contrast-enhanced angiography.

8858-73, Session 16

Joint image reconstruction and motion parameter estimation for free-breathing navigator-gated cardiac MRI

Mehmet Akcakaya, Reza Nezafat, Beth Israel Deaconess Medical Ctr. (United States)

We develop a reconstruction technique for free-breathing cardiac MRI acquisitions with prospective random undersampling and a respiratory navigating (NAV) approach that only gates the central k-space. In these acquisitions, central k-space is acquired within a pre-specified NAV gating window, minimizing motion artifacts. For the randomly undersampled outer k-space, if the NAV signal corresponding to a k-space segment is outside the gating window, the segment is rejected, but not re-acquired. The proposed compressed sensing-based reconstruction algorithm then jointly estimates the motion parameters of the NAV-rejected outer k-space and the image itself. Feasibility of the algorithm is demonstrated in coronary MRI.

8858-74, Session 16

Exploiting local low-rank structure in higher-dimensional MRI applications

Joshua D. Trzasko, Mayo Clinic College of Medicine (United States)

In many clinical MRI applications, not one but a series of images is acquired. Techniques that promote intra- and inter-image sparsity have recently emerged as powerful strategies for accelerating MRI applications; however, sparsity alone cannot always describe the complex relationships that exist between images in these series. In this talk, sparsity, we will discuss the modeling of higher-dimensional MRI signals as matrices and tensors, and why promoting these signals to be low-rank (and, specifically, locally low-rank) can effectively identify and exploit these complex relationships. Example applications including calibrationless parallel and training-free dynamic MRI will be demonstrated.

8858-75, Session 16

Accelerated dynamic MRI using sparse dictionary learning

Mathews Jacob, Univ. of Iowa (United States); Sajan Goud Lingala, The Univ. of Iowa (United States)

We propose a novel sparse dictionary learning frame work to recover dynamic images from under-sampled mea- surements. Unlike the recent low rank schemes, the proposed scheme models the the dynamic signal as a sparse linear combination of temporal basis functions chosen from a large dictionary. Both the basis functions and the sparse coefficients are estimated from the undersampled data. We show that this representation is much more compact com- pared to the low rank models. We also develop an efficient majorize-minimize algorithm to estimate the sparse model coefficients and the dictionary directly from the measured data. A continuation strategy is proposed to be robust to local minima. We compare the proposed scheme against low rank models and demonstrate improved reconstructions in the context of myocardial perfusion imaging in the presence of motion.

8858-76, Session 16

Prospective motion correction for functional MRI using sparsity and Kalman filtering

Daniel S. Weller, Douglas C. Noll, Jeffrey A. Fessler, Univ. of Michigan (United States)

We develop a novel motion estimation and correction method for use during acquisition of functional magnetic resonance imaging time series. We model the changes in image content between frames as sparse, leveraging the image-domain sparsity of the functional activation changes. We combine this sparse residual model with extended Kalman filter-like tracking, and we implement this method efficiently using a combination of variable splitting and the alternating direction method of multipliers. We demonstrate the efficacy of our method on simulated data by comparing temporal correlations of the data corrected prospectively against data corrected only through post-processing.

Conference 8859: UV, X-Ray, and Gamma-Ray Space Instrumentation for Astronomy XVIII

Sunday - Monday 25–26 August 2013

Part of Proceedings of SPIE Vol. 8859 UV, X-Ray, and Gamma-Ray Space Instrumentation for Astronomy XVIII

8859-1, Session 1

The advanced x-ray spectroscopic imaging observatory (AXSIO)

Jay A. Bookbinder, Smithsonian Astrophysical Observatory (United States); Robert Petre, Andrew F. Ptak, NASA Goddard Space Flight Ctr. (United States); Randall K. Smith, Smithsonian Astrophysical Observatory (United States)

AXSIO will deliver at least 10-50X the effective area of current x-ray telescopes, which in combination with its two focal plane instruments (the imaging X-ray Microcalorimeter Spectrometer and the X-ray Grating Spectrometer) will result in a 100-fold increase in capability over the current generation of instruments for high-res¬olution spectroscopy. AXSIO covers the 0.1 - 12keV energy range, complementing the capabilities of the next generation observatories such as ALMA, LSST, JWST, and 30-m ground-based telescopes These instruments allow AXSIO to accomplish most of the IXO science goals at a significantly reduced complexity and cost. These capabilities will enable studies of a broad range of scientific questions such as what happens close to a black hole, how supermassive black holes grow, how large scale structure forms, and what are the connections between these processes?

This paper presents an overview of the AXSIO mission science drivers, its capabilities relative to its IXO heritage, its optics and instrument options, the status of its technology development programs, and the mission implementation approach.

8859-2, Session 1

Designing the AXSIO microcalorimeter detector focal plane for optimal science return

Randall K. Smith, Harvard-Smithsonian Ctr. for Astrophysics (United States); Simon R. Bandler, NASA Goddard Space Flight Ctr. (United States); Jay A. Bookbinder, Harvard-Smithsonian Ctr. for Astrophysics (United States); Richard L. Kelley, Robert Petre, Andrew F. Ptak, Stephen J. Smith, NASA Goddard Space Flight Ctr. (United States)

Recent advances in X-ray microcalorimeters enable a wide range of possible focal plane designs for the X-ray Microcalorimeter Spectrometer (XMS) instrument on the future Advanced X-ray Spectroscopic Imaging Observatory (AXSIO). Small pixel designs (<100 um) allow for oversampling of the PSF that enable observations at both high count rates and high energy resolution. Pixel designs utilizing multiple absorbers attached to single transition-edge sensors can extend the focal plane to cover a significantly larger field of view, albeit at a cost in maximum count rate and energy resolution. We have optimized the focal plane with respect to likely targets, mirror and aperture size, focal plane complexity, and technology readiness, and will present the design, along with suggestions towards the key technology developments that will be needed for the AXSIO mission.

8859-4, Session 1

The development of µROSI: micro roentgen satellite instrument

Lars Tiedemann, Elias Breunig, Maria Fürmetz, Walter Kink, Peter Predehl, Max-Planck-Institut für Extraterrestrische Physik (Germany)

The µROSI miniature x-ray telescope is the first x-ray telescope specifically designed for an amateur micro satellite. Its mission is to perform an all-sky survey in the soft x-ray band on board the Italian satellite Max-Valier. Due to the limitations imposed by the small size of the spacecraft, the instrument features a silicon drift detector (SDD) with very low power consumption and a focusing optics that consists of 12 nesting mirror shells. With a field of view of 1° µROSI will perform an all-sky survey flying in sun-synchronous orbit (SSO).

This paper describes the overall telescope design and gives an overview of all major components and subsystems. All subsystems have been tested with flight-like engineering models. The results of these tests are presented in this paper.

The silicon drift detector of the µROSI telescope has been tested with a breadboard electronics and the engineering model of the electronics is currently being manufactured.

One demonstrator mirror shell has been produced and tested in the PANTER x-ray test facility to verify the X-ray properties.

A structural qualification model has been built and tested with mass dummies. It showed sufficient load capability to sinusoidal, random vibration and shock loads.

One key element of the thermal control subsystem for the detector is a latent cold storage which operates at -16°C to guarantee an optimal operating temperature for the SDD. The selected phase change material has been tested successfully in a vacuum chamber.

8859-5, Session 1

Novel space communication technology based on x-ray photons

Baosheng B. Zhao, Lizhi Sheng, Chuanxing Wu, Yong'an Liu, Xi'an Institute of Optics and Precision Mechanics (China)

Radio frequency(RF) communication has been used in space satellite communications for decades and is still the workhorse for current space projects. Laser based optical communication is a hot topic recently because of its good security, relatively higher data rate, and small antenna size. However, bottlenecks such as the limited transmission distance, the wavelength dispersion during the transmission and mass SWAP burden (size, weight and power) on spacecraft are still major challenges, which restricts the future applications in deep space. A novel space communication method is presented in this paper based on X-ray photons. As a result of X-ray's short wavelength and great penetrability, a communication technology of long distance signal transmission in space can be achieved with smaller volume, lower weight and lower power. Therefore, X-ray communication (XCOM) is especially valuable to the deep space missions, which will be able to realize higher data rates, smaller SWAP than with RF and laser communications. High-speed modulation and high-sensitivity detection of X-rays are two major technical issues for the X-ray communication. A Grid-controlled Modulated X-ray tube (GMXT) is proposed and developed as X-ray transmitter. The communication signal is coded and applied to the modulated grid electrode, and then the corresponding X-ray signals are generated and sent out. X-ray detector based on micro-channel plate(MCP) is used as communication receiver because of its high temporal resolution. An audio communication experiment system based on XCOM is successfully demonstrated in laboratory including the X-ray transmitter and the receiver. The communication speed reaches 64 kilobits per second in a vacuum tube of 6 meters long. As a new concept of space communication, X-ray communication will have more important scientific significance and application prospects when technologies for X-ray modulation and detection are further developed.

8859-6, Session 2

A small mission featuring an imaging x-ray polarimeter with high sensitivity

Martin C. Weisskopf, NASA Marshall Space Flight Ctr. (United States); Luca Baldini, Ronaldo Bellazini, Alessandro Brez, Istituto Nazionale di Fisica Nucleare (Italy); Enrico Costa, INAF - IASF Roma (Italy); Richard Dissly, Ball Aerospace & Technologies Corp. (United States); Ronald F. Elsner, NASA Marshall Space Flight Ctr. (United States); Sergio Fabiani, INAF - IASF Roma (Italy); Giorgio Matt, Univ. degli Studi di Roma Tre (Italy); Massimo Minuti, Istituto Nazionale di Fisica Nucleare (Italy); Fabio Muleri, INAF - IASF Roma (Italy); Stephen L. O'Dell, NASA Marshall Space Flight Ctr. (United States); Michelle Pinchera, Istituto Nazionale di Fisica Nucleare (Italy); Brian Ramsey, NASA Marshall Space Flight Ctr. (United States); Alda Rubini, INAF - IASF Roma (Italy); Carmelo Sgrò, Istituto Nazionale di Fisica Nucleare (Italy); Paolo Soffitta, INAF - IASF Roma (Italy); Gloria Spandre, Istituto Nazionale di Fisica Nucleare (Italy)

We present a detailed description of a small mission capable of obtaining high precision and meaningful measurement of the X-ray polarization of a variety of different classes of cosmic X-ray sources. Compared to other ideas that have been suggested this experiment has demonstrated in the laboratory a number of extremely important features relevant to the ultimate selection of such a mission by a funding agency. The most important of these questions are: 1) Have you demonstrated the sensitivity to a polarized beam at the energies of interest (i.e. the energies which represent the majority (not the minority) of detected photons from the X-ray source of interest? 2) Have you demonstrated that the device's sensitivity to an unpolarized beam is really negligible and/or quantified the impact of any systematic effects upon actual measurements? We present our answers to these questions backed up by laboratory measurements and give an overview of the mission.

8859-8, Session 2

Plans for the next grape balloon flight

Mark L. McConnell, Peter F. Bloser, Camden Ertley, Jason S. Legere, James M. Ryan, Steven P. Longworth, Christopher M. Bancroft, Colin Frost, The Univ. of New Hampshire (United States); Mark Chutter, The Univ. of New Hampshire (United States)

The Gamma RAy Polarimeter Experiment (GRAPE) was first flown on a 26-hour balloon flight in the fall of 2011. GRAPE consists of an array of Compton polarimeter modules (based on traditional scintillation technologies) designed to operate in the energy range from 50 keV up to 500 keV. The ultimate goal of our program is to operate GRAPE in a wide FoV configuration for the study of gamma-ray bursts. For the first balloon flight, GRAPE was configured in a collimated mode to facilitate observations of known point sources. The Crab nebula/pulsar, the active Sun, and Cygnus X-1 were the primary targets for the first flight. Although the Crab was detected, the polarization sensitivity was worse than expected, in part because of a lower-than-expected altitude for much of the flight. Only upper limits on the Crab polarization were obtained. This paper will review the plans for the next GRAPE balloon flight, which is scheduled to take place in the fall of 2014 from Ft. Sumner, NM. These plans involve several modifications designed to improve the polarization sensitivity. These modifications include an expansion of the array of polarimeter modules from 16 to 24 and improvements to the instrument shielding. Sensitivity estimates of the resulting instrument, based on GEANT4 simulations, will be presented.

8859-9, Session 2

Scintillator gamma-ray detectors with silicon photomultiplier readouts for high-energy astronomy

Peter F. Bloser, Jason S. Legere, Christopher M. Bancroft, Mark L. McConnell, James M. Ryan, The Univ. of New Hampshire (United States)

Space-based gamma-ray detectors for high-energy astronomy face strict constraints of mass, volume, and power, and must endure harsh operating environments. Scintillator materials have a long history of successful operation under these conditions, and new materials offer greatly improved performance in terms of efficiency, time response, and energy resolution. The use of scintillators in space remains constrained, however, by the mass, volume, and fragility of the associated light readout device, typically a vacuum photomultiplier tube (PMT). Recently developed silicon photomultipliers (SiPMs) offer gains and efficiencies similar to those of PMTs, but with greatly reduced mass and volume, high ruggedness, and no high-voltage requirements. We have therefore been investigating the use of SiPM readouts for scintillator gamma-ray detectors, with an emphasis on their suitability for space- and balloon-based instruments for high-energy astronomy. We present our most recent results, including spectroscopy and timing measurements for lanthanum bromide scintillators with SiPM readouts, pulse-shape discrimination using organic scintillators with SiPM readouts, and comparison to Monte Carlo simulations of the optical scintillation light collection using Geant4. We also describe potential applications of SiPM readouts to specific high-energy astronomy instrument concepts.

8859-10, Session 3

Progress of the x-ray CCD camera development for the eROSITA telescope

Norbert Meidinger, Max-Planck-Institut für Extraterrestrische Physik (Germany)

The eROSITA space telescope is presently developed for the determination of cosmological parameters and the equation of state of dark energy via evolution of clusters of galaxies. It will perform in addition a census of the obscured black hole growth in the Universe. Furthermore, the instrument development was strongly motivated by the intention of a first imaging X-ray all-sky survey above an energy of 2 keV.

eROSITA is scientific payload on the Russian research satellite SRG and the mission duration is scheduled for 7.5 years. The instrument comprises an array of 7 identical and parallel aligned telescopes. The mirror system is of Wolter-I type and the focal plane is equipped with a PNCCD camera for each of the telescopes. This instrumentation permits spectroscopy and imaging of X-rays in the energy band from 0.3 keV to 10 keV with a field of view of 1.0 degree. The camera development is done at the Max-Planck-Institute for extraterrestrial physics and in particular the key component, the PNCCD sensors, have been designed and fabricated at its semiconductor laboratory. All produced devices were tested and the best selected for the eROSITA project.

Based on calculations, simulations, and experimental testing of prototype systems, the flight cameras have been configured. We describe the camera system, its operation on board of the satellite, and the performance. The most recent test results will be presented as well as the status of the instrument development.

8859-11, Session 3

Soft x-ray imager onboard ASTRO-H

Hiroshi Tsunemi, Kiyoshi Hayashida, Hiroshi Nakajima, Osaka Univ. (Japan); Takeshi Go Tsuru, Takaaki Tanaka, Kyoto Univ. (Japan); Tadayasu Dotani, Masanobu Ozaki, Chikara Natsukari, Hiroshi Tomida, Japan Aerospace Exploration Agency (Japan); Junko S. Hiraga, The Univ. of Tokyo (Japan); Takayoshi Kohmura, Kogakuin Univ. (Japan); Hiroshi Murakami, Rikkyo Univ. (Japan); Koji Mori, Makoto Yamauchi, Isamu Hatsukade, Univ. of Miyazaki (Japan); Aya Bamba, Aoyama Gakuin Univ. (Japan)

The Soft X-ray Imager, SXI, is an X-ray CCD camera onboard the ASTRO-H satellite to be launched in 2015. ASTRO-H will carry two types of soft X-ray detector and two types of hard X-ray detector. The soft X-ray detectors are the X-ray calorimeter, SXS, and the SXI covering the energy range between 0.3keV and 12keV. The SXS has an excellent energy resolution of 7eV@6keV with a narrow field of view of 3 arcmin square while the SXI has a medium energy resolution of 150eV@6keV with a large field of view of 38 arcmin square. The X-ray mirror will achieve an effective area of 360cm2@6keV. We employ 4 CCDs of P-channel type in back-side configuration with a depletion layer of 200um. The working temperature is to be -110C deg by using two mechanical coolers. The temperature stability is less than 1C deg. We performed the radiation tests for CCDs and ASICs and confirmed that the SXI would properly function through the entire mission life of ASTRO-H. The inside the SXI body is completely isolated from that of the satellite so that we can avoid a possible contamination problem. We employ an optical blocking filter at the top of the SXI as well as the optical blocking layer on the CCD surface. We passed the CDR and will assemble the FM in 2013. We have fixed the on-board software and are now in developing analysis software on the ground. We will report the SXI status and its expected performance in orbit.

8859-12, Session 3

Performance of the x-ray CCD coated with optical blocking layer for SXI onboard ASTRO-H

Takayoshi Kohmura, Kogakuin Univ. (Japan); Hiroshi Tsunemi, Kiyoshi Hayashida, Hiroshi Nakajima, Naohisa Anabuki, Ryo Nagino, Shutaro Ueda, Osaka Univ. (Japan); Tadayasu Dotani, Masanobu Ozaki, Hiroshi Tomida, Chikara Natsukari, Japan Aerospace Exploration Agency (Japan); Takeshi Go Tsuru, Takaaki Tanaka, Masayoshi Nobukawa, Hiroyuki Uchida, Kyoto Univ. (Japan); Junko S. Hiraga, The Univ. of Tokyo (Japan); Koji Mori, Makoto Yamauchi, Univ. of Miyazaki (Japan); Shoma Ikeda, Kenta Kaneko, Kazunari Yabe, Kogakuin Univ. (Japan)

We have developed the back-illuminated X-ray CCD camera (BI-CCD) for Soft X-ray Imager (SXI) onboard ASTRO-H. Since the X-ray CCD, especially BI- CCD has a high sensitivity not only for in X-ray but also in both visible light and UV light, X-ray CCD for SXI is directly coated the 100nm thick aluminum on the surface of the CCD in order to block visible light, and we name this aluminum layer OBL (Optical Blocking Layer).

We have developed the prototype CCD for SXI coated with OBL and we have measured the energy resolution, dark current, quantum efficiency(QE), and so on by irradiating the soft X-ray at KEK-PF and the X-ray from 55Fe. We obtained the energy resolution and QE to be150-170eV at 5.9keV and 84% at 0.54keV, respectively. We have also measured the optical transmission of OBL and confirmed the optical transmission of OBL is an order of 10-5 which was the same order of our expected value.

We will show the performance of the proto-type CCD for SXI, mainly focusing on the QE in detail.

8859-13, Session 3

Advancement of readout ASIC for onboard x-ray CCD cameras

Hiroshi Nakajima, Shouta Inoue, Ryo Nagino, Naohisa Anabuki, Kiyoshi Hayashida, Hiroshi Tsunemi, Osaka Univ. (Japan); John P. Doty, Noqsi Aerospace, Ltd. (United States); Hirokazu Ikeda, Japan Aerospace Exploration Agency (Japan)

We report on the development and the performance evaluation of the readout ASIC for an onboard X-ray CCD camera. The quick and low-noise readout is essential for the pile-up free imaging spectroscopy with the future highly sensitive telescope. Our goal is the readout noise of 5e- rms at the pixel rate of 1Mpix/sec, which is about 10 times faster than those of the currently working detectors. We had successfully developed a low-noise mixed-signal Application Specific Integrated Circuit (ASIC) as the front-end electronics of SXI (Soft X-ray Imager) onboard the ASTRO-H satellite. The combination of the differential voltage amplifier and the second-order Delta Sigma ADC achieved the input equivalent noise of 30μV (6e- rms assuming the node sensitivity of 5μV/e-) at the pixel rate of 80kpix/sec. The radiation hardened layout design on an epitaxial wafer realized the sufficiently high tolerance for both of the total dose and the single event effect in a low earth orbit. However, the noise performance was limited at the pixel rate higher than 250kpix/sec. Then we have been developing the new ASIC with the fourth-order Delta Sigma modulators to enhance its inherent noise-shaping performance. It consists of four identical circuits that process the CCD signal simultaneously. A 3mm square bare chip will be packed into a 15mm square ceramic package. We present the performance of the ASIC such as the input equivalent noise, integrated non-linearity, effective signal range as well as the results obtained from the integrated test with a fully-depleted P-channel X-ray CCD.

8859-14, Session 3

Modeling contamination migration on the Chandra x-ray observatory ii

Stephen L. O'Dell, Douglas A. Swartz, NASA Marshall Space Flight Ctr. (United States); Neil L. Tice, Lockheed Martin Space Systems Co. (United States); Paul P. Plucinsky, Smithsonian Astrophysical Observatory (United States); Catherine E. Grant, Herman L. Marshall, Massachusetts Institute of Technology (United States); Alexey Vikhlinin, Smithsonian Astrophysical Observatory (United States); Allyn F. Tennant, NASA Marshall Space Flight Ctr. (United States)

During its first 14 years of operation, the cold (about -60°C) optical blocking filter of the Advanced CCD Imaging Spectrometer (ACIS), aboard the Chandra X-ray Observatory, has accumulated a growing layer of molecular contamination that attenuates low-energy x rays. Over the past few years, the accumulation rate, spatial distribution, and composition may have changed, perhaps partially related to changes in the operating temperature of the ACIS housing. This evolution of the accumulation of the molecular contamination has motivated further analysis of contamination migration on the Chandra X-ray Observatory, particularly within and near the ACIS cavity. To this end, the current study employs a higher-fidelity geometric model of the ACIS cavity, detailed thermal modeling based upon monitored temperature data, and an accordingly refined model of the molecular transport.

8859-15, Session 4

Proton irradiation test to scintillator-directory-coupled CCD onboard FFAST

Ryo Nagino, Hiroshi Nakajima, Masaaki Sadamoto, Masayuki Sasaki, Hiroshi Tsunemi, Kiyoshi Hayashida, Naohisa Anabuki, Osaka Univ. (Japan); Hisashi Kitamura, Yukio Uchihori, National Institute of Radiological Sciences (Japan)

FFAST is a large area sky survey mission at hard X-ray region by using a spacecraft formation flying. It consists of two small satellites, a telescope satellite, carrying a multilayer super mirror, and a detector satellite, carrying scintillator-deposited CCDs (SD-CCDs).

SD-CCD is the imaging device which realized sensitivity to 80 keV by pasting up a scintillator on CCD directly. Soft X-ray events are directly detected in the CCD. On the other hand, Hard X-ray events are converted to optical photons by the scintillator and then the CCD detects the photons. We have obtained the spectrum with 109Cd and successfully detected the events originated from the CsI.

For a space use of a CCD, we have to understand aged deterioration of CCD in high radiative environments. In addition, in the case of SD-CCD, we must investigate the influence of radio-activation of a scintillator.

We performed experiments of proton irradiation to the SD-CCD as space environmental tests of cosmic rays.

The SD-CCD is irradiated with the protons with the energy of 100 MeV and neglected for about 150 hours.

As a result, the derived CTI profile of SD-CCD is similarly to ones of XIS/Suzaku and NeXT4 CCD/ASTRO-H.

In contrast, CTIs derived from the data within 4 hours after irradiation is 10 times or more larger than the ones after 150 hours. This may be due to influence of an annealing.

We also report a performance study of SD-CCD, including the detection of scintillation events, before proton irradiation.

8859-16, Session 4

High-resolution soft x-ray spectrometry using the electron-multiplying charge-coupled device (EM-CCD)

David J. Hall, The Open Univ. (United Kingdom); Andrew D. Holland, e2v Ctr. for Electronic Imaging at The Open Univ. (United Kingdom); James H. Tutt, Matthew Soman, The Open Univ. (United Kingdom); Neil J. Murray, e2v Ctr. for Electronic Imaging at The Open Univ. (United Kingdom); Bernd Schmitt, Thorsten Schmitt, The Open Univ. (United Kingdom)

The Electron-Multiplying (EM) CCD shares a similar structure to the CCD except for the additional gain register that multiplies signal before the addition of read-noise, offering sub-electron effective read-noise at high frame-rates.

EM-CCDs were proposed for the dispersive spectrometer on the International X-ray Observatory to bring sub-300eV X-rays above the noise, increasing the science yield. The high-speed, low-noise performance of the EM-CCD brought added advantages of reduced dark current and stray-light per frame, reducing cooling and filtering requirements. To increase grating efficiency, several diffracted spectral orders were co-located and the inherent energy resolution of the detector was required for order separation. Although the spectral resolution of the EM-CCD is degraded by the gain process, it was shown that the EM-CCD could achieve required separation.

The SAXES spectrometer at the Advanced Resonant Spectroscopy Beamline of the SLS (Paul Scherrer Institute) currently uses a CCD, with charge spreading between pixels limiting the spatial resolution to 24um. Through improving the spatial resolution below 5um alongside upgrading the grating, a factor of two energy resolution improvement could theoretically be made. With the high-speed, low-noise performance of the EM-CCD, photon-counting modes could allow the use of centroiding techniques to improve the resolution. Using various centroiding techniques, a spatial resolution of 2um has been achieved experimentally, demonstrating the benefits of this detector technology for soft X-ray spectrometry.

This paper summarises the use of EM-CCDs from our first investigations for IXO through to our latest developments from ground-based testing for synchrotron-research and looks beyond to future possibilities.

8859-17, Session 4

Performance of buried channel MOSFETS in 0.18-µm CMOS image sensors

Konstantin D. Stefanov, The Open Univ. (United Kingdom)

Buried channel MOSFETs are typically used as source followers in high performance CCDs due to their lower 1/f noise compared with surface channel devices. In CMOS image sensors the transistors are almost invariably surface channel and exhibit typical 1/f and RTS noise sources. The question we are addressing is whether better noise performance could be achieved by using buried channel devices in CMOS image sensors for space and other imaging science applications. As a part of the development of buried channel CCD process in 0.18 µm CMOS, a number of buried n-channel MOSFETs were designed and manufactured. The I-V and noise characteristics of the transistors are presented and discussed, and compared with standard surface channel devices.

8859-18, Session 4

Characterization of Si hybrid CMOS detectors for use in the soft x-ray band

Zachary Prieskorn, Christopher V. Griffith, Abraham D. Falcone, Stephen D. Bongiorno, David N. Burrows, The Pennsylvania State Univ. (United States)

We report on the characterization of four HAWAII Hybrid Si CMOS detectors developed for use as X-ray detectors as part of a joint program between Penn State University and Teledyne Imaging Sensors. Interpixel capacitive crosstalk (IPC) has been measured for standard H1RG detectors as well as a specially developed H2RG that uses a unique bonding structure. The H2RG shows significant reduction in IPC, as reported by Griffith et al. 2012. Energy resolution at 1.5 & 5.9 keV was measured as well as read noise for each detector. Dark current as a function of temperature is reported from 150 – 210 K. We also estimate dark current figure of merit for each detector.

8859-19, Session 4

First reports on development of new short wavelength (UV, VUV, and EUV) detector arrays incorporating quantum-dot-coated CMOS array

Ross Robinson, Rochester Institute of Technology (United States) and National Institute of Standards and Technology (United States); Zoran Ninkov, Denis Cormier, Rochester Institute of Technology (United States); Uwe Arp, National Institute of Standards and Technology (United States); Suraj K. Bhaskaran, Thermo Fisher Scientific Inc. (United States); Robert E. Vest, National Institute of Standards and Technology (United States); Alan D. Raisanen, Rochester Institute of Technology (United States); Carey Beam, Herb Ziegler, Thermo Fisher Scientific Inc. (United States)

This work reports on the process development and first results of a 2D CMOS imaging array coated with quantum dots to add deep UV response. The structure of standard silicon detectors limits short wavelength sensitivity to the near UV. Quantum dots are 2-10nm diameter nanoparticles, whose fluorescence wavelength is determined by particle size. The quantum dots absorb incident UV, VUV and EUV light. The emitted fluorescence is a narrow wavelength distribution of visible light to which the underlying silicon detector array is sensitive. The coated detector remains sensitive to visible light and gains increased sensitivity at shorter wavelengths. By coating a standard off-the-shelf silicon detector, large area deep UV detectors are realizable without the

use of high bandgap materials. Initial VUV device testing was conducted at the NIST Synchrotron Ultraviolet Radiation Facility (SURF III) in Gaithersburg MD.

8859-20, Session 4

Superlattice-doped detectors for FUV, EUV, soft x-ray and particle imaging and spectroscopy

Michael E. Hoenk, Alexander G. Carver, Todd J. Jones, Matthew R. Dickie, Shouleh Nikzad, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); Joseph A. Sgro, Alacron, Inc. (United States); Shraga Tsur, Applied Materials (Israel)

In 1996, scientists studying images from the Extreme UV Imaging Telescope (EIT) discovered burn-in patterns in the CCDs, including a dark grid-shaped pattern caused by long term EUV exposure through a nickel grid proximate to the surface. The damage observed on EIT is typical of silicon detectors exposed to FUV, EUV, and x-ray radiation, in which accumulated damage to the Si-SiO2 interface leads to charging and instabilities of the detector surface. JPL and Alacron have recently demonstrated a high-performance CMOS camera capable of far ultraviolet imaging with high quantum efficiency and exceptional long-term stability. In this paper, we present experimental results and band structure calculations that illuminate the unique properties of superlattice-doped detectors. The stability of superlattice doped detectors is predicted by the insensitivity of the surface band structure to radiation-induced interface traps and confirmed experimentally by long-term exposure of superlattice-doped CMOS imaging arrays to radiation from pulsed excimer lasers. Superlattice doped CMOS imaging arrays, large-format CCDs, electron-multiplied CCDs, and silicon photodiodes have been demonstrated for several FUV and particle imaging and spectroscopy instrument applications.

8859-21, Session 5

Responsivity mapping techniques for the non-positional CCD: the swept charge device CCD236

Phillipa H. Smith, The Open Univ. (United Kingdom); Neil J. Murray, e2v Ctr. for Electronic Imaging at The Open Univ. (United Kingdom); Calum MacCormick, Jason P. D. Gow, D. Wetherill, Edgar A. H. Allanwood, The Open Univ. (United Kingdom); Peter J. Pool, e2v technologies plc (United Kingdom); Andrew D. Holland, The Open Univ. (United Kingdom)

The e2v CCD236 is a swept charge device (SCD) designed as a soft X-ray detector, 0.8 keV to 10 keV, and benefits from improvements in design over the previous generation of SCD to allow for increased detector area, a reduction in split X-ray events and improvements to radiation hardness. Being continually clocked and read-out there is no positional information making responsivity variations hard to measure. Due to the small size of previous devices this wasn't as important. With the larger areas of the device, variations in responsivity are possible and could affect scientific output.

This paper describes novel techniques to achieve a responsivity map across the device using masking and XRF, and spot illumination from an organic light-emitting diode (OLED). The results of this technique should allow a deeper understanding of the device sensitivity and allow better data interpretation in SCD applications.

8859-22, Session 5

The gas pixel detector at the focus of an x-ray optics

Paolo Soffitta, Enrico Costa, Sergio Fabiani, Fabio Muleri, Alda Rubini, INAF - IASF Roma (Italy); Daniele Spiga, Gianpiero Tagliaferri, Giovanni Pareschi, Stefano Basso, Oberto Citterio, INAF - Osservatorio Astronomico di Brera (Italy); Ronaldo Bellazzini, Alessandro Brez, Luca de Ruvo, Massimo Minuti, Michele Pinchera, Carmelo Sgrò, Gloria Spandre, Istituto Nazionale di Fisica Nucleare (Italy); Vadim Burwitz, Wolfgang Burkert, Max-Planck-Institut für Extraterrestrische Physik (Germany); Benedikt Menz, Max-Planck-Institut für Wissenschaftsgeschichte (Germany); Gisela Hartner, Max-Planck-Institut für Extraterrestrische Physik (Germany)

X-ray polarimeters at the focus of an X-ray optics, with or without true 2-d imaging capability, have been proposed in many space missions to arrive at the sensitivity requested by astrophysical models.

Here we show the performances of the Gas Pixel Detector as focal plane instrument of one of the two flight models of JET-X mirrors that were supposed to fly aboard the former Spectrum-X Gamma mission. One unit is currently flying on-board SWIFT while three units are still available for future X-ray experiments.

We measured the imaging capability of the GPD by using the same configuration as that routinely used for measuring the Point Spread Function of an optics. We show that most of its characteristics are preserved notwithstanding the inclined penetration in the GPD drift region, we also verified that the position resolution of the detector provides a negligible contribution.

We used a different configuration to place upper limits on the spurious polarization induced by the reflection at grazing incidence that theoretical calculations indicate to be well below practical detection.

Such calibration measurements were carried out at the PANTER X-ray test facility of the Max-Planck-Institut für extraterrestrische Physik.

8859-23, Session 5

Lifetime estimation of a time projection chamber x-ray polarimeter

Joanne E. Hill, Joel K. Black, Kristina M. Montt de Garcia, Lubos Brieda, Patsy L. Dickens, Asami Hayato, Douglas L. Hawk, NASA Goddard Space Flight Ctr. (United States)

The Gravity and Extreme Magnetism Small Explorer (GEMS) Mission X-ray polarimeter Instrument (XPI) was designed to measure the polarization of 23 sources over the course of its 9 month mission. The XPI consists of two telescopes each with a polarimeter assembly at the focus of a grazing incidence mirror. To make sensitive polarization measurements the GEMS Polarimeter Assembly (PA) employed a gas detection system based on a Time Projection Chamber (TPC) technique. Gas detectors are inherently at risk of degraded performance arising from contamination from outgassing of internal detector components or due to loss of gas.

This paper describes the design and the materials used to build a prototype of the flight polarimeter with the required GEMS lifetime. We report the results from outgassing measurements of the polarimeter subassemblies and assemblies, enclosure seal tests, life tests, and performance tests that demonstrate that the GEMS lifetime is achievable. Finally we report performance measurements and the lifetime enhancement from the use of a getter.

8859-24, Session 5

Hydrogen cells as narrowband geo-coronal lyman-alpha rejection filters for astrophysical photometry

Keith Redwine, Stephan R. McCandliss, Brian T. Fleming, Russell Pelton, Johns Hopkins Univ. (United States)

The JHU Rocket Group is developing hydrogen cells to act as narrow-band Hydrogen Lyman-alpha rejection filters for ultraviolet detectors. A heated tungsten filament in the cell produces free hydrogen atoms by photodissociation of molecular gas contained in the cell. This creates a high enough optical depth at Lyman-alpha, effectively filtering out incident geo-coronal Lyman-alpha emission. This suppression of geo-coronal light will make possible observations of astrophysical sources into the Far-UV below 1200 angstroms, down to the lithium-fluoride edge at 1040 angstroms. The flux attenuation of the hydrogen cells will be measured in a vacuum monochrometer testbed. The goal is to produce a usable hydrogen cell design to be easily mounted on a detector for photometric observations of astronomical sources in the Far-UV below 1200 angstroms, which has been a region often contaminated by bright geo-coronal Lyman-alpha emission.

8859-25, Session 5

Calibration and flight qualification of FORTIS

Brian T. Fleming, Stephan R. McCandliss, Keith Redwine, Mary E. Kaiser, Paul D. Feldman, Johns Hopkins Univ. (United States); Jeffery W. Kruk, Alexander S. Kutyrev, Mary J. Li, Samuel H. Moseley, NASA Goddard Space Flight Ctr. (United States); Oswald H. Siegmund, Adrian Martin, John V. Vallerga, Sensor Sciences, LLC (United States)

The Johns Hopkins University sounding rocket group has completed the assembly and calibration of the Far-ultraviolet Off Rowland-circle Telescope for Imaging and Spectroscopy (FORTIS); a sounding rocket borne multi-object spectro-telescope designed to provide spectral coverage of up to 43 separate targets in the 900 - 1800 Angstrom bandpass over a 30' x 30' field-of-view. Utilizing an autonomous targeting system coupled to a central imaging channel, FORTIS is capable of selecting the far-UV brightest regions of the target area and acquiring medium resolution (R~400) spectra in redundant dual-order spectroscopic channels with ~40cm^2 of effective area at 1200 Angstroms. The maiden launch of FORTIS is scheduled for May 10, 2013 out of the White Sands Missile Range, targeting the extended spiral galaxy M61 and nearby companion NGC4301. We report on the final flight calibrations and qualifications of the instrument, including the component characterization and the results of environmental testing at Wallops Flight Facility, as well as the early flight science results, if available.

8859-26, Session 5

Radiometric calibration of the SWRI ultraviolet reflectance chamber (SWURC) far-ultraviolet reflectometer

Preston L. Karnes, Southwest Research Institute (United States) and St. Mary's Univ. (United States); Kurt D. Retherford, Gregory S. Winters, Michael W. Davis, Stephen M. Escobedo, Eric R. Schindhelm, Eric C. Bassett, Edward L. Patrick, Joel W. Parker, G. Randall Gladstone, Thomas K. Greathouse, Lori M. Feaga, S. Alan Stern, Southwest Research Institute (United States)

The Southwest Research Institute Ultraviolet Reflectance Chamber (SwURC) is a highly capable UV reflectometer chamber and data acquisition system designed to provide bidirectional scattering data of various surfaces and materials. The chamber provides laboratory-based UV reflectance measurements of water frost/ice, lunar soils, simulants, and analogs to support interpretation of UV reflectance data from the Lyman Alpha Mapping Project (LAMP) Lunar Reconnaissance Orbiter (LRO). A deuterium lamp illuminates a monochromator with a nominal wavelength range of 115 nm to 210 nm. The detector scans emission angles -85° to +85° in the principal plane. Liquid nitrogen passed through the sample mount enables constant refrigeration of tray temperatures down to 78 K to form water ice and other volatile samples. The SwURC can be configured to examine a wide range of samples and materials through the use of custom removable sample trays, connectors, and holders. Calibration reference standard measurements reported here include Al/MgF2 coated mirrors for specular reflection and Fluorilon for diffuse reflectances. This calibration work is a precursor to reports of experiments measuring the far-UV reflectance of water frost, lunar simulants, and Apollo soil sample 10084 in support of LRO-LAMP.

8859-27, Session 6

Characterization, modeling, and management of the COS FUV detector lifetime

David J. Sahnow, Alessandra Aloisi, Azalee Bostroem, John H. Debes, Julia Duval, Justin Ely, Philip E. Hodge, Gerard A. Kriss, Derck Massa, Cristina M. Oliveira, Rachel Osten, Space Telescope Science Institute (United States); Steven Osterman, Univ. of Colorado at Boulder (United States); Steven V. Penton, Charles Proffitt, Paule Sonnentrucker, Space Telescope Science Institute (United States)

The Far Ultraviolet (FUV) detector of the Cosmic Origins Spectrograph (COS) on the Hubble Space Telescope (HST) uses a large-format, two-segment microchannel plate detector with a Cross Delay-Line anode. Since the installation of COS into HST in 2009, the detector's properties have continually evolved, and changes to both sensitivity and microchannel plate gain have been observed.

In order to maximize the lifetime of the detector, we have been monitoring its local properties as a function of time, cumulative exposure, and other factors, and we have constructed models to predict its future evolution. These models will allow us to actively manage the microchannel plate high voltage levels and the location of the spectra on the detector in order to extend its life without limiting its scientific use.

We are also tracking the global sensitivity of the detector, which has been decreasing since installation; the rate of degradation has been found to vary with time, and appears to be correlated with solar activity.

We will discuss our progress in extending the life of the detector, with a focus on the results since July 2012, when the spectra were move to a second lifetime position.

8859-28, Session 6

Performance results from in-flight commissioning of the Juno ultraviolet spectrograph (Juno-UVS)

Thomas K. Greathouse, G. Randall Gladstone, Michael W. Davis, David C. Slater, Maarten H. Versteeg, Kristian B. Persson, Brandon C. Walther, Gregory S. Winters, Steven C. Persyn, John S. Eterno, Southwest Research Institute (United States)

We present a description of the Juno ultraviolet spectrograph (Juno-UVS) and results from its in-flight commissioning performed between December 5th and 13th 2011 and its first periodic maintenance between October 10th and 12th 2012. Juno-UVS is a modest power (9.0 W) ultraviolet spectrograph based on the Alice instruments now in flight aboard the European Space Agency's Rosetta spacecraft and NASA's New Horizons spacecraft, and the LAMP instrument aboard

NASA's Lunar Reconnaissance Orbiter. However, unlike the other Alice spectrographs, Juno-UVS sits aboard a spin stabilized spacecraft. The Juno-UVS scan mirror allows for pointing of the slit approximately ±30° from the spacecraft spin plane. This ability gives Juno-UVS access to half the sky at any given spacecraft orientation. The planned 2 rpm spin rate for the primary mission results in integration times per 0.2° spatial resolution element per spin of only ~17 ms. Thus, for calibration purposes, data were retrieved from many spins and then remapped and co-added to build up exposure times on bright stars to measure the effective area, spatial resolution, scan mirror pointing positions, etc. The primary job of Juno-UVS will be to characterize Jupiter's UV auroral emissions and relate them to in-situ particle measurements. The ability to point the slit will make operations more flexible, allowing Juno-UVS to observe the atmospheric footprints of magnetic field lines through which Juno flies, giving a direct connection between energetic particle measurements on the spacecraft and the far-ultraviolet emissions produced by Jupiter's atmosphere in response to those particles.

8859-30, Session 6

An improved wide-field camera for imaging Earth's plasmasphere at 30.4 nm

Michael W. Davis, G. Randall Gladstone, Jerry Goldstein, Southwest Research Institute (United States); Bill R. Sandel, The Univ. of Arizona (United States); Thomas K. Greathouse, Kurt D. Retherford, Gregory S. Winters, Southwest Research Institute (United States)

The Extreme Ultraviolet Imager (EUV) aboard NASA's IMAGE mission studied the distribution of singly ionized helium (He+) in the Earth's plasmasphere by imaging its emission at 30.4 nm. This instrument consisted of three separate camera heads, each with a 28° field-of-view, with 0.6° resolution. We described an improved imaging system that can simultaneously image a 40° field-of-view with 0.45° resolution utilizing only one camera head. This imager also increases throughput over the heritage EUV imager by a factor of four due to improvements in optical coatings, detector technology, and a larger entrance aperture.

8859-31, Session 7

Adaptive digital pulse shaping methods for image readout on the Jupiter ultraviolet dynamic explorer instrument of the ESA juice spacecraft

Steven A. Leach, Jon S. Lapington, Univ. of Leicester (United Kingdom)

A high speed low noise detector signal shaping scheme is under development for application in the proposed Jupiter Ultraviolet Dynamic Explorer (JUDE) instrument for the ESA led Jupiter Icy Moons Explorer (JUICE) mission.

The proposed system will facilitate the UV science objectives of JUICE; Auroral imaging and FUV spectroscopy. JUDE will directly view each hemisphere of Jupiter in addition to separately imaging the Europa, Callisto and Ganymede moons, requiring a combination of high dynamic range and high spatial resolution. A main objective is to develop a radiation tolerant imager that can adapt to these different luminosity conditions with flexibility to optimise the image spatial resolution against the photon event rate.

The JUDE instrument system proposes Microchannel Plate detectors (MCP) coupled with a novel image readout, the Capacitive Division Image Readout (C-DIR). The readout requires four charge measurement channels comprising low noise Charge Sensitive Preamplifiers (CSP) and fast signal conditioning amplifiers. The fast signal from each channel is captured and digitised before application of adaptive digital pulse shaping and peak detection algorithms.

Our experimental setup comprises a low noise analogue frontend electronics unit coupled to a four channel fast digitiser which allows analysis of various digital shaping methods and assessment of their adaptability; their electronic noise performance versus photon event rate trade-off envelope.

This paper presents a comparison of results from digitally coded Moving Window Deconvolution (MWD) and Semi-Gaussian shaping techniques with adjustable parameters to assess their adaptability to the changing photon count rates predicted for the different Jupiter mission phases.

8859-32, Session 7

The capacitive division image readout; a novel imaging device for microchannel plate detectors

Jon S. Lapington, Steven A. Leach, Univ. of Leicester (United Kingdom); Thomas Conneely, Photek Ltd. (United Kingdom)

The Capacitive Division Image Readout (C-DIR) is a simple and novel image readout for photon counting detectors with major performance advantages. C-DIR is a charge centroiding device comprising three elements; (i) a resistive anode providing event charge localization, event current return path and electrical isolation from detector high voltage, (ii) a dielectric substrate which capacitively couples the event transient signal to the third element, (iii) the readout device; an array of capacitively coupled electrodes which divides the signal among the readout charge measurement nodes.

The resistive anode and dielectric substrate constitute the rear interface of the detector and capacitively couple the signal to the external C-DIR readout device. The C-DIR device is a passive, multilayer printed circuit board type device comprising a matrix of isolated electrodes whose geometries define the capacitive network. C-DIR is manufactured using conventional PCB geometries and is straightforward and economical to construct.

C-DIR's robustness and simplicity belie its performance advantages. Its capacitive nature avoids partition noise, the Poisson noise associated with collection of discrete charges. The dominant noise limiting position resolution is electronic noise. However C-DIR also presents a low input capacitance to the readout electronics, minimising this noise component thus maximising spatial resolution. Optimisation of the C-DIR pattern-edge geometry can provide ~90% linear dynamic range.

We present image resolution and linearity measurements of the C-DIR device with microchannel plate detectors and describe various electronic charge measurement scheme designed to exploit the full performance potential of the C-DIR device.

8859-33, Session 7

Opaque gallium nitride photocathodes in UV imaging detectors with microchannel plates

Anton S. Tremsin, Jeffrey S. Hull, Oswald H. Siegmund, Jason B. McPhate, Univ. of California, Berkeley (United States); Amir M. Dabiran, SVT Associates, Inc. (United States)

The recent progress in the development of novel Microchannel Plates (MCPs) manufactured with the help of the Atomic Layer Deposition technology broadens the range of temperatures which are available for the MCP processing, in particular during the photocathode deposition. At the same time, the surface on which the photocathodes are deposited can be modified for a better compatibility with the good quality films grown directly on top surface of the MCP, serving as opaque photocathodes. The opaque photocathodes have generally shown better efficiency compared to the semitransparent configuration even on the flat substrates as there is no compromise need to be found between the depth of absorption and the escape length for the photoelectrons. In case of MCP photocathodes the improvement of detection efficiency can be expected from the fact that photocathode deposited inside the pores is illuminated at a grazing angle and thus photoelectrons are produced closer to the surface and have only short range to travel in order to create an electron avalanche.

8859-34, Session 7

Performance characteristics of atomic layer functionalized microchannel plates

Oswald H. Siegmund, Jason B. McPhate, Univ. of California, Berkeley (United States)

A new method of fabricating microchannel plates has been investigated, employing microcapillary arrays of borosilicate glass that are deposited with resistive and secondary emissive layers using atomic layer deposition. Microchannel plates of this kind have been made in sizes from 33 mm to 200 mm, with pore sizes of 10 µm and 20 µm, pore length to diameter ratios of 80:1, bias angles of 8°, and open areas from 60% to 83%. Tests with single MCPs and MCP pairs have been done and show good imaging quality, gain comparable to conventional MCPs, low background rates (~ 0.085 events sec-1 cm-2), fast pulse response, and good ageing characteristics. The quantum efficiency for bare and alkali halide coated MCPs is similar to conventional MCPs, and we have also been able to deposit opaque GaN(Mg) cathodes directly onto these MCPs.

8859-36, Session 8

The DXL and storm sounding rocket mission

Nicholas E. Thomas, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland (United States); Jennifer A. Carter, Univ. of Leicester (United Kingdom); Meng P. Chiao, Dennis J. Chornay, Yaireska M. Collado-Vega, Michael R. Collier, NASA Goddard Space Flight Ctr. (United States); Thomas E. Cravens, The Univ. of Kansas (United States); Massimiliano Galeazzi, Univ. of Miami (United States); John W. Keller, NASA Goddard Space Flight Ctr. (United States); Dimitra Koutroumpa, Univ. de Versailles Saint-Quentin-en Yvelines (France); Kip D. Kuntz, Johns Hopkins Univ. (United States); Maria M. Kuznetsova, NASA Goddard Space Flight Ctr. (United States); Susan T. Lepri, Univ. of Michigan (United States); Daniel McCammon, Kelsey Morgan, Univ. of Wisconsin-Madison (United States); Frederick S. Porter, NASA Goddard Space Flight Ctr. (United States); Krishna Prasai, Univ. of Miami (United States); Andrew M. Read, Univ. of Leicester (United Kingdom); Ina P. Robertson, The Univ. of Kansas (United States); Steven F. Sembay, Univ. of Leicester (United Kingdom); David G. Sibeck, Steven L. Snowden, NASA Goddard Space Flight Ctr. (United States); Youaraj Uprety, Univ. of Miami (United States); Brian M. Walsh, NASA Goddard Space Flight Ctr. (United States)

The objective of the Diffuse X-ray emission from the Local Galaxy (DXL) sounding rocket experiment is to distinguish the soft X-ray emission from the Local Hot Bubble (LHB) from that produced via Solar Wind Charge eXchange (SWCX). Enhanced interplanetary helium density in the helium focusing cone provides a spatial variation to the SWCX that can be identified by scanning through the focusing cone using an X-ray instrument with a large grasp. DXL consists of two large proportional counters refurbished from the Aerobee-IV payload used during the Wisconsin All Sky Survey. The counters utilize P-10 fill gas and are covered by a thin Formvar window (with Cyasorb UV-24 additive) supported on a nickel mesh. DXL's large grasp is 10 cm? sr for both the ? and ? keV bands. DXL was successfully launched from White Sands Missile Range, New Mexico on December 12, 2012 using a Mk70 Black Brant IX sounding rocket.
