Cadmium Zinc Telluride (CZT) detectors have been the workhorse in hard X-ray astronomy for a decade now, implemented in many X-ray observatories e.g. SWIFT, NuSTAR and more recently in ASTROSAT. Response matrix for pixelated CZT detectors requires precise modelling of the X-ray lines as a function of energy. Instead of showing simple Gaussian feature, these lines exhibit a long tail at lower energies because of trapping of the charge carriers due to their low mobility (μ) and lifetime (?). This effect is found to be more significant for high energy photons as the probability of charge loss increases with the depth of interaction. Therefore, precise line modelling in case of CZT detectors needs accurate measurement of μ? values for electrons and holes. For pixelated detectors, other significant components in the line modelling come from the crosstalk between pixels due to charge sharing, fluorescence photons and Compton scattering. Here we present experimental measurements of mobility and lifetime for 4 cm X 4 cm and 5 mm thick CZT detectors with pixel dimension of 2.5 mm X 2.5 mm, procured from Orbotech Medical Solutions (similar to the modules used in CZTI, Astrosat). Here we independently generate pixel-wise response matrix for the CZT modules and test in laboratory by fitting a known continuum spectra in 20 – 50 kev using a X-ray gun. We also draw a comparison between the μ? response matrix involving all physical processes and a Gaussian response matrix using the same continuum source of radiation.

9601-2, Session 1

CdTe focal plane detector for hard x-ray focusing optics

Paul Seller, Matthew D. Wilson, Matthew C. Veale, Andreas Schneider, STFC Rutherford Appleton Lab. (United Kingdom); Jessica A. Gaskin, Colleen Wilson-Hodge, NASA Marshall Space Flight Ctr. (United States); Steven D. Christe, Albert Y. Shih, NASA Goddard Space Flight Ctr. (United States)

The demand for higher resolution x-ray optics (a few arcseconds or better) in the areas of astrophysics and solar science has, in turn, driven the development of complementary detectors. These detectors should have fine pixels, necessary to appropriately oversample the optics at a given focal length, and an energy response also matched to that of the optics. At Rutherford Appleton Laboratory, we have developed a 3-side abuttable, 20mm x 20mm CdTe-based detector with 250 micron square pixels (80x80 pixels) which achieves 1keV FWHM @60keV and gives full spectroscopy between 5keV and 200keV. An added advantage of these detectors is that they have a full-frame readout rate of 10 kHz. Working with NASA Goddard Space Flight Center and Marshall Space Flight Center, we have tiled 4 of these 1mm-thick CdTe detectors into a 2x2 array for use at the focal plane of a balloon-borne hard-x-ray telescope, and are considering configurations suitable for astrophysics and solar space-based missions. This effort encompasses the fabrication and testing of flight-suitable front-end electronics and calibration of the assembled detector arrays. We explain the operation of the pixelated ASIC readout and measurements, front-end electronics development, preliminary X-ray imaging and spectral performance, and plans for full calibration of the detector assemblies. Work done in conjunction with the NASA Centers is funded through the NASA Science Mission Directorate Astrophysics Research and Analysis Program.

9601-3, Session 1

First results from the OGRESS sounding rocket payload

Thomas D. Rogers, Univ. of Colorado at Boulder (United States); Ted B. Schultz, James H. Tutt, Jake McCoy, Drew M. Miles, Randall L. McEntaffer, The Univ. of Iowa (United States)

The Off-plane Grating Rocket for Extended Source Spectroscopy (OGRESS) is a soft x-ray spectrograph designed to observe diffuse sources such as Supernova Remnants and large gas clouds with significantly increased resolving power over current state-of-the-art. OGRESS's large field of view and off-plane diffraction gratings will produce a spatially integrated spectrum of the entire Cygnus Loop with the highest resolving power ever achieved between 300 - 1000 eV. OGRESS uses Gaseous Electron Multiplier (GEM) detectors. OGRESS, scheduled to launch in the spring of 2015, will demonstrate the first comprehensive success of GEM spaceflight.

9601-4, Session 1

Technological developments with the OGRE focal plane array

James H. Tutt, Randall L. McEntaffer, Casey T. DeRoo, Ted B. Schultz, The Univ. of Iowa (United States); Andrew D. Holland, Neil J. Murray, The Open Univ. (United Kingdom); Karen Holland, David Colebrook, David Farn, XCAM Ltd. (United Kingdom); Daniel P. Weatherill, The Open Univ. (United Kingdom); Anthony M. Evagora, XCAM Ltd. (United Kingdom); Drew M. Miles, The Univ. of Iowa (United States); William W. Zhang, NASA Goddard Space Flight Ctr. (United States)

The Off-plane Grating Rocket Experiment (OGRE) is a suborbital rocket payload designed to test the spectral resolution performance of an instrument based on off-plane reflection grating technology. Through the combination of silicon based optics, blazed and radially groove off-plane gratings and Electron Multiplying Charge-Coupled Devices (EM-CCDs), an instrument with resolution in excess of 1500 across the soft X-ray bandpass is possible within a suborbital payload.

Using the design of OGRE's optics (focusing and grating) along with specifications on readout speed and signal-to-noise, an EM-CCD camera array was baselined for the focal plane array (CCD207-40). This detector has a large imaging area and, due to the use of multiplication gain, can be read out quickly with a sub-electron readout noise. The decision to use this detector on OGRE defined the aspects that the mechanical, vacuum and cooling systems needed to include.

A prototype for the camera has been developed using the similar but more commercially available CCD207-10. This prototype has allowed the designs for the final camera system to be optimised in preparation of the construction of the flight camera.

This paper analyses the optical design of OGRE and how this led to the decision to use EM-CCDs on the focal plane. The requirements that this decision put on the mechanical, thermal and electrical properties of the camera are then covered before looking at the progress made with the prototype system.

9601-5, Session 1

A primer for telemetry interfacing in accordance with NASA standards using low cost FPGAs

Jake A. McCoy, Ted B. Schultz, The Univ. of Iowa (United States); Thomas D. Rogers, Univ. of Colorado at Boulder (United States); James H. Tutt, Drew M. Miles, Thomas J. Peterson, Randall L. McEntaffer, The Univ. of Iowa (United States)

X-ray detector systems on sounding rocket payloads often require interfacing asynchronous outputs with a synchronously clocked telemetry stream. Though this can be handled with an on-board computer, there are several low cost alternatives including custom hardware, microcontrollers, and Field-Programmable Gate Arrays (FPGAs). FPGAs have the advantage of being highly flexible and reconfigurable while also having low power consumption and a small printed circuit board footprint. This paper outlines how a telemetry interface for detectors on a sounding rocket with asynchronous parallel digital output can be implemented using FPGAs and minimal custom hardware. It also serves as a guide for working with Pulse Code Modulation (PCM) formatted telemetry encoding and the Inter-Range Instrumentation Group (IRIG) Chapter 10 digital recording standard. Additionally, methods for testing the telemetry interface with a simulated telemetry chain in the small laboratory setting are discussed. This includes using FPGAs as detector simulators and recording data according to the IRIG Chapter 10 format using a PCM processor and data acquisition software. Finally, this paper discusses specifically how the telemetry interface is integrated into the electronics assembly of the Off-plane Grating Rocket for Extended Source Spectroscopy (OGRESS) with the associated custom hardware.

9601-6, Session 2

Modeling contamination migration on the Chandra X-ray Observatory: III

Stephen L. O'Dell, Douglas A. Swartz, NASA Marshall Space Flight Ctr. (United States); Neil W. Tice, Massachusetts Institute of Technology (United States); Paul P. Plucinsky, Smithsonian Astrophysical Observatory (United States); Catherine E. Grant, Herman L. Marshall, Massachusetts Institute of Technology (United States); Alexey A. Vikhlinin, Smithsonian Astrophysical Observatory (United States); Allyn F. Tennant, NASA Marshall Space Flight Ctr. (United States)

During its first 16 years of operation, the cold (about -60°C) optical blocking filter of the Advanced CCD Imaging Spectrometer (ACIS), aboard the Chandra X-ray Observatory, has accumulated a growing layer of molecular contamination that attenuates low-energy x rays. Over the past few years, the accumulation rate, spatial distribution, and composition have changed. This evolution has motivated further analysis of contamination migration within and near the ACIS cavity. To this end, the current study employs a high-fidelity geometric model of the ACIS cavity, detailed thermal modeling based upon temperature data, and a refined model of the molecular transport.

9601-7, Session 2

Soft x-ray, UV, and optical transmission of the contamination blocking filer for the soft x-ray imager (SXI) on board ASTRO-H

Takayoshi Kohmura, Yuta Sato, Koki Tamasawa, Shoma Tanno, Yuma Yoshino, Shintaro Kuwano, Masato Ando, Kenta Kaneko, Tokyo Univ. of Science (Japan); Tadayasu Dotani, Masanobu Ozaki, Hiroshi Tomida, Masashi Kimura, Keisuke Kondo, Japan Aerospace Exploration Agency (Japan); Hiroshi Tsunemi, Kiyoshi Hayashida, Naohisa Anabuki, Hiroshi Nakajima, Ryo Nagino, Juyong Kim, Ritsuko Imatani, Hiroyuki Kurubi, Osaka Univ. (Japan)

The X-ray detectors, such as cooled X-ray CCD, onboard satellite are contaminated by the outgas which is produced from organic material used in satellites. This contamination causes to a significant reduction of detection sensitivity of X-ray detectors. We have developed Contamination Blocking Filter (CBF), which is consisted with 120nm thick Aluminum and 200nm thick Polyimide, to prevent the contamination to Back-Illuminated-CCD (BI-CCD) for Soft X-ray Imager (SXI) onboard ASTRO-H. The CBF plays important role to block UV and optical as well as to prevent the contamination to SXI.

We carried out UV and optical transmission measurement and obtained their transmission to be <10^-3 at 40eV and < 10-5 at 500nm, respectively. As these results, we confirmed the shading performance of CBF was as expected from its design thickness.

The quantum efficiency of SXI is determined by the X-ray transmission of CBF especially in the soft X-ray energy range below 2keV therefore to measure the soft X-ray transmission of CBF is necessary. Therefore we measured soft X-ray transmission of CBF at the High Energy Accelerator Research Organization (KEK), and obtained the X-ray transmission of CBF in the energy from 0.02 to 2.2keV by 1eV step and obtained its high X-ray transmission to be ?60% at 0.5keV. In this measurement, we also measured the absorption edges around C-K, O-K, Al-K, and N-K, including X-ray absorption fine structure (XAFS).

We will report X-ray, UV, and optical transmission in detail.

9601-8, Session 2

The optical blocking filter for the ATHENA wide field imager: baselign design and preliminary performance evaluation

Marco Barbera, Univ. degli Studi di Palermo (Italy) and INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Graziella Branduardi-Raymont, Univ. College London (United Kingdom); Alfonso Collura, INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Andrea Comastri, INAF - Osservatorio Astronomico di Bologna (Italy); Tadeusz Kamisi?ski, AGH Univ. of Science and Technology (Poland); Ugo Lo Cicero, INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Norbert Meidinger, Max-Planck-Institut für extraterrestrische Physik (Germany); Teresa Mineo, INAF - Istituto di Astrofisica Spaziale e Fisica Cosmica di Palermo (Italy); Silvano Molendi, INAF - IASF Milano (Italy); Adam Pilch, AGH Univ. of Science and Technology (Poland); Luigi Piro, INAF - IASF Roma (Italy); Miroslaw Rataj, Space Research Ctr. (Poland); Gregor Rauw, Univ. de Liège (Belgium); Luisa Sciortino, Univ. degli studi di Palermo (Italy); Salvatore Sciortino, INAF - Istituto di Astrofisica Spaziale e Fisica Cosmica di Palermo (Italy); Piotr Wawer, Space Research Ctr. (Poland)

ATHENA is an advanced X-ray observatory designed to pursue the science theme "Hot and Energetic Universe" selected by ESA for the L2 mission within the Cosmic Vision science programme (launch scheduled in 2028). One of the key instruments of ATHENA is the Wide Field Imager (WFI) which will provide imaging in the 0.1-15 keV band over a 40' diameter field of view, simultaneously with spectrally and time-resolved photon counting.

The WFI camera, based on arrays of DEPFET active pixels, is also sensitive

to UV/VIS photons, with an electron-hole pair production efficiency in the UV/VIS that is larger than for X-ray photons. Optically generated photo-electrons may degrade the spectral resolution as well as change the energy scale by introducing a signal offset. For this reason, the use of an X-ray transparent optical blocking filter is needed to allow the observation of all type of X-ray sources that present a UV/Visible bright counterpart.

We present the filter baseline design, which includes the use of an Aluminum layer directly deposited on-chip and an external filter mounted on a filter wheel, we show the performances based on simulations and preliminary measurements conducted on test samples, and discuss criticalities to reach TRL 5-6 during the instrument technology development phase.

9601-9, Session 2

Development of the strontium iodide coded aperture (SICA) instrument

Lee Mitchell, Bernard F. Phlips, U.S. Naval Research Lab. (United States)

Europium-doped strontium iodide (SrI2:Eu) detectors have recently become available and the material is a strong candidate to replace existing detector technology currently used for space-based gamma-ray astrophysics research. The detectors have a typical energy resolution of 3.2% at 662 keV, a significant improvement over the 6.5% energy resolution of thallium-doped sodium iodide (NaI(Tl)). SrI2:Eu is comparable to lanthanum bromide (LaBr3) in both energy resolution and density, but LaBr3 has an added internal background due to natural occurring 138La. With a density of 4.59 g/cm and a Zeff of 49 SrI2:Eu has a high efficiency for MeV gamma ray detection. Coupling this with recent improvements in silicon photomultiplier technology (i.e. no bulky photomultiplier tubes) creates high density, large area, low power detector arrays with good energy resolution. The Naval Research Laboratory is in the process of developing a prototype array of SrI2:Eu that would consist of an 8x8 array of pixels, each read out by a silicon photomultiplier. The array would be used to demonstrate coded aperture imaging performance and to perform Compton imaging tests in combination with silicon detectors. The energy resolution of SrI2:Eu makes it ideal for use in as the backplane of a Compton telescope or a coded aperture imager. A discussion on the overall design, simulations used to optimize the design, and initial tests of the electronic components will be presented.

9601-10, Session 3

The speedster-EXD: a new event-triggered hybrid CMOS x-ray detector

Christopher V. Griffith, Abe D. Falcone, Zachary R. Prieskorn, David N. Burrows, The Pennsylvania State Univ. (United States)

We present the characterization of a new event driven x-ray hybrid CMOS detector developed by Penn State University in collaboration with Teledyne Imaging Sensors. Along with its low susceptibility to radiation damage, low power consumption, and fast read-out time to avoid pile-up, the Speedster-EXD has been designed with the capability to limit its readout to only those pixels containing charge, thus enabling even faster effective frame rates. The threshold for the comparator in each pixel can be set by the user so that only pixels with signal above the set threshold are read out. The Speedster-EXD hybrid CMOS detector also has two new in-pixel features that reduce noise from known noise sources: (1) a low-noise, high-gain CTIA amplifier to eliminate interpixel capacitance crosstalk and (2) in-pixel CDS subtraction to reduce kTC noise. We present the read noise, dark current, interpixel capacitance, energy resolution, and gain variation measurements of two Speedster-EXD detectors.

9601-11, Session 3

Soft x-ray quantum efficiency and other characteristics of x-ray sensitive Si hybrid CMOS detectors

Zachary R. Prieskorn, The Pennsylvania State Univ. (United States); Stephen D. Bongiorno, Johns Hopkins Univ. (United States); David N. Burrows, Abraham D. Falcone, Christopher V. Griffith, The Pennsylvania State Univ. (United States); Jonathan A. Nikoleyczik, Univ. of Maryland, College Park (United States)

X-ray sensitive Si Hybrid CMOS detectors (HCDs) will potentially replace X-ray CCDs in the focal planes of future X-ray observatories. HCDs improve on the performance of CCDs in numerous areas: faster read out time, windowed read out modes, less susceptibility to radiation & micrometeoroid damage, and lower power consumption. Understanding detector quantum efficiency (QE) is critical for estimating the sensitivity of an X-ray instrument. We report on QE across the soft X-ray band for four Teledyne Imaging Sensors HyViSI HCDs. These detectors have Al optical blocking filters deposited directly on the Si substrate; these filters vary in thickness from 180 – 1000 Å. We estimate the QE with a 1D slab absorption model and find good agreement between the model and our results across an energy range from 0.677 – 8.05 keV. We will also describe upcoming work to measure the sub-pixel QE of these detectors using the Penn State 47 m X-ray facility and give a broad overview of the current capabilities and development plans for X-ray sensitive HCDs.

9601-12, Session 3

Recent progress in the development of Kyoto's x-ray astronomical SOI pixel sensor

Takeshi G. Tsuru, Hideaki Matsumura, Ayaki Takeda, Takaaki Tanaka, Kyoto Univ. (Japan); Shinya Nakashima, Institute of Space and Astronautical Science (Japan); Yasuo Arai, High Energy Accelerator Research Organization, KEK (Japan); Koji Mori, Ryota Takenaka, Yusuke Nishioka, Univ. of Miyazaki (Japan); Takayoshi Kohmura, Tokyo Univ. of Science (Japan); Takaki Hatsui, Yoshiki Kohmura, RIKEN SPring-8 Ctr. (Japan); Takashi Kameshima, Japan Synchrotron Radiation Research Institute (Japan); Dai Takei, RIKEN SPring-8 Ctr. (Japan); Shoji Kawahito, Keiichiro Kagawa, Keita Yasutomi, Hiroki Kamehama, Sumeet Shrestha, Shizuoka Univ. (Japan)

We have been developing monolithic active pixel sensors, X-ray SOIPIXs, based on the Silicon-On-Insulator (SOI) CMOS technology for next-generation X-ray astronomy satellites. The event trigger output function implemented in each pixel offers a high time resolution of ~micro sec, which allows us to reduce non-X-ray background dominating the high X-ray energy band above 5–10 keV by adopting anti-coincidence technique. We reported in the previous SPIE conference (AS14) that we achieved the depletion layer thickness of 500 micron and the energy resolution of 300 eV (FWHM) at 6keV. In this paper, we give recent progress from the development. (1) In the previously developed device, a significant tail component was seen in the X-ray spectral response due to non-uniformity of the charge collection efficiency. We realized in-pixel circuitry disturbs the electric fields in the depletion layer through which signal charge is collected. We successfully solved the non-uniformity problem by modifying the placement of the in-pixel circuitry. (2) We developed a new device equipped with programable gain amplifiers and differential amplifiers are implemented (see paper in OP318 by Shrestha for details on the device description). We report the X-ray performances of the device. (3) We introduce the status of the development of a larger size device with the imaging area of 22mm x 14mm towards practical use.

9601-13, Session 3

The soft x-ray imager (SXI) for the ASTRO-H Mission

Takaaki Tanaka, Kyoto Univ. (Japan); Hiroshi Tsunemi, Kiyoshi Hayashida, Osaka Univ. (Japan); Takeshi G. Tsuru, Kyoto Univ. (Japan); Tadayasu Dotani, Institute of Space and Astronautical Science (Japan); Hiroshi Nakajima, Naohisa Anabuki, Ryo Nagino, Shutaro Ueda, Osaka Univ. (Japan); Hiroyuki Uchida, Masayoshi Nobukawa, Kyoto Univ. (Japan); Masanobu Ozaki, Japan Aerospace Exploration Agency (Japan); Chikara Natsukari, Institute of Space and Astronautical Science (Japan); Hiroshi Tomida, Masashi Kimura, Japan Aerospace Exploration Agency (Japan); Junko S. Hiraga, The Univ. of Tokyo (Japan); Takayoshi Kohmura, Tokyo Univ. of Science (Japan); Hiroshi Murakami, Tohoku Gakuin Univ. (Japan); Koji Mori, Makoto Yamauchi, Isamu Hatukade, Yusuke Nishioka, Univ. of Miyazaki (Japan); Aya Bamba, Aoyama Gakuin Univ. (Japan); John P. Doty, Noqsi Aerospace, Ltd. (United States)

The Soft X-ray Imager (SXI) is an X-ray CCD camera onboard the ASTRO-H X-ray observatory, which is scheduled to be launched in Japanese fiscal year 2015. The SXI consists of four CCD chips with an imaging area of 31 mm by 31 mm arranged in a 2 by 2 grid so that it covers a large field-of-view of 38 arcmin by 38 arcmin. The CCDs are P-channel back-illumination type with a depletion layer of 200 micron, with which the SXI covers the energy range between 0.4 keV and 12 keV. The CCD chips are cooled down to -110 degrees Celsius or below by using a Stirling cooler. As is done for the CCD camera onboard the Suzaku satellite, artificial charges are injected to selected rows of the CCDs in order to recover charge transfer inefficiency due to radiation damage caused by in-orbit cosmic rays.

We completed the flight model fabrication and performed an end-to-end verification test and on-ground calibration. Through the tests, we verified the functionality and performance of the SXI system and obtained an energy resolution of ~ 160 eV (FWHM) for 5.9 keV X-rays. The same level of the energy resolution was also obtained with the SXI onboard the satellite during the first integration test. We then carried out vibration, acoustic, and thermal-vacuum tests before the final integration and testing. In the presentation, we will report the status of the SXI and the detector performance expected in orbit.

9601-14, Session 3

Initial results from a cryogenic proton irradiation of a p-channel CCD

Jason P. D. Gow, David J. Hall, Ben J. Dryer, Simeon Barber, Andrew D. Holland, Neil J. Murray, The Open Univ. (United Kingdom)

The displacement damage hardness that can be achieved using p-channel charged coupled devices (CCD) was originally demonstrated in 1997 and since then a number of other studies have demonstrated an improved tolerance to radiation-induced CTI when compared to n-channel CCDs. A number of recent studies have also shown that the temperature history of the device after the irradiation impacts the performance of the detector, linked to the mobility of defects at different temperatures. This study describes the initial results from an e2v technologies p-channel CCD204 irradiated at 153 K with a 10 MeV equivalent proton fluences of 4.0?109 and 8.0?109 protons.cm-2. The number of defects identified using trap pumping, charge transfer efficiency and dark current immediately after irradiation, over a period of time with the device held at 153 K and then after different periods of time at room temperature are described.

9601-15, Session 4

Hard x-ray polarimetry with Astrosat-CZTI

Tanmoy Chattopadhyay, Santosh V. Vadawale, Physical Research Lab. (India); A. R. Rao, Tata Institute of Fundamental Research (India)

Astrosat is the forthcoming Indian satellite dedicated for astronomical studies. CdZnTe Imager (CZTI), one of the five instruments in Astrosat, is a pixelated spectroscopic instrument sensitive in 20-150 kev range. Because of its pixilation nature and significant Compton scattering efficiency at energies beyond 100 kev, it is possible to measure polarization in X-rays exploiting the Compton scattering technique at energies beyond its primary energy range. The simulation and experimental results clearly show that the flight configuration of Astrosat-CZTI will be capable of polarisation measurement in hard X-rays in 100 -300 keV. Detailed polarimetric background analysis and therefrom the polarimetric sensitivity estimations show that CZTI will be able to measure polarization for few highly polarized bright hard X-ray sources, e.g. CygX1 - black hole source, Crab pulsar including any new transient sources in Astrosat lifetime . We discuss the possibility of constraining various possible hard X-ray emission mechanisms in black hole sources and emission geometries in X-ray pulsars with CZTI polarimetry.

9601-16, Session 4

Development of the wide field imager for Athena

Norbert Meidinger, Kirpal Nandra, Arne Rau, Markus Plattner, Max-Planck-Institut für extraterrestrische Physik (Germany); Joern Wilms, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Marco Barbera, Univ. degli Studi di Palermo (Italy)

The WFI (Wide Field Imager) instrument is planned to be one of two complementary focal plane cameras on ESA's Athena satellite.

It combines unprecedented survey power through its large field of view of 40 arcmin with a high count-rate capability (> 1 Crab). The energy resolution of the silicon sensor is state-of-the-art in the energy band of interest from 0.1 keV to 15 keV. At energy of 6 keV for example, the full width at half maximum of the line shall be not worse than 150 eV until the end of the mission.

The performance is accomplished by a set of DEPFET active pixel sensor matrices with a pixel size well suited to the angular resolution of 5 arc sec (on-axis) of the mirror system.

Each DEPFET pixel is a combined detector-amplifier structure with a MOSFET integrated onto a fully depleted 450 micron thick silicon bulk.

Two different types of DEPFET sensors are planned for the WFI instrument: A set of large-area sensors to cover the physical size of 14 cm x 14 cm in the focal plane and a single gateable DEPFET sensor matrix optimized for the high count rate capability of the instrument.

An overview will be given about the presently developed instrument concept and design, the status of the technology development, and the expected performance. An outline of the project organization, the model philosophy as well as the schedule will complete the presentation about the Wide Field Imager for Athena.

9601-17, Session 4

LAMP: a micro-satellite based soft x-ray polarimeter for astrophysics

Rui She, Hua Feng, Tsinghua Univ. (China); Paolo Soffitta, Fabio Muleri, INAF - IASF Roma (Italy); Renxin Xu, Peking Univ. (China); Hong Li, Tsinghua Univ. (China); Ronaldo

Bellazzini, Istituto Nazionale di Fisica Nucleare (Italy); Zhanshan Wang, Tongji Univ. (China); Daniele Spiga, Giovanni Pareschi, Gianpiero Tagliaferri, Kashmira Tayabaly, Bianca Salmaso, INAF - Osservatorio Astronomico di Brera (Italy); Yafeng Zhan, Jianhua Lu, Tsinghua Univ. (China)

The Lightweight Asymmetry and Magnetism Probe (LAMP) is micro-satellite mission concept dedicated for astronomical X-ray polarimetry and is currently under early phase study. It consists of segmented paraboloidal multilayer mirrors with a collecting area of about 1300 cm2 to reflect and focus 250 eV X-rays, which will be detected by position sensitive detectors at the focal plane. The primary targets of LAMP include the thermal emission from the surface of pulsars and synchrotron emission produced by relativistic jets in blazars. The expected sensitivity of LAMP will allow us to detect polarization or place a tight upper limit from about 10 pulsars and 20 blazars. In addition to measuring magnetic structures in these objects, LAMP will also enable us to discover bare quark stars if they exist, whose thermal emission is expected to be zero polarized, while the thermal emission from neutron stars is thought to be highly polarized. Here we present an overview of the mission concept, its science objectives and simulated observational results.

9601-18, Session 4

NASA x-ray surveyor mission: a concept study

Jessica A. Gaskin, NASA Marshall Space Flight Ctr. (United States); Alexey Vikhlinin, Harvard-Smithsonian Ctr. for Astrophysics (United States); Martin Weisskopf, NASA Marshall Space Flight Ctr. (United States); Harvey Tananbaum, Harvard-Smithsonian Ctr. for Astrophysics (United States)

Over the past 16 years, NASA's Chandra X-ray Observatory has provided an unparalleled means for exploring the high-energy universe with its half-arcsecond angular resolution. Chandra studies have deepened our understanding of galaxy clusters, active galactic nuclei, galaxies, supernova remnants, neutron stars, black holes, and solar system objects. As we look beyond Chandra, it is clear that comparable or even better angular resolution with greatly increased photon throughput is essential to address ever more demanding science questions—such as formation and subsequent growth of black hole seeds at very high redshifts; emergence of the first galaxy groups; and details of feedback over a large range of scales from galaxies to galaxy clusters. Recently, we initiated a concept study for such a mission. This concept study starts from a strawman payload comprising a high-resolution mirror assembly and an instrument set, which may include an X-ray calorimeter, a wide-field imager, and a dispersive grating spectrometer and its readout. The mirror assembly would consist of highly nested, thin, grazing-incidence mirrors, for which a number of technical approaches are currently under development—including adjustable X-ray optics, differential deposition, and modern polishing techniques applied to a variety of substrates. This study benefits from previous studies of large-area missions carried out over the past two decades and, in most areas, points to mission requirements no more stringent than those of Chandra.

9601-19, Session 4

The eROSITA X-ray Observatory

Vadim Burwitz, Peter Predehl, Max-Planck-Institut für extraterrestrische Physik (Germany)

In 2016 the X-ray observatory eROSITA will be launched on board the Russian Spectrum-RG mission from Baikonur. eROSITA with its 7 even X-ray telescopes will first be used to perform eight all-sky surveys over a period of 4 years continuing with a 3 year pointed observation phase. With the impending launch date on the horizon, the hardware phase is coming to an end, therefore the thorough testing of the cameras, electronics, and mirrors is in high gears. These tests will then culminate with an end to end test at MPEs PANTER X-ray test facility before shipment to Russia. Here we describe the status of the Observatory and yield insights into the challenges we faced while making eROSITA.

9601-34, Session 4

ATHENA: system design and implementation for a next generation x-ray telescope

Mark R. Ayre, Marcos Bavdaz, Ivo Ferreira, Martin Linder, Eric Wille, David H. Lumb, European Space Agency (Netherlands)

ATHENA, Europe's next generation x-ray telescope, has recently been selected for the 'L2' slot in ESA's Cosmic Vision Programme, with a mandate to address the 'Hot and Energetic Universe' Cosmic Vision science theme. The mission is currently in the Assessment/Definition Phase (A/B1), with a view to formal adoption after a successful System Requirements Review in 2019. This paper will describe the reference mission architecture and spacecraft design produced during Phase 0 by the ESA Concurrent Design Facility (CDF), in response to the challenging technical requirements and programmatic boundary conditions.

The main technical requirements and their mapping to resulting design choices will be presented, at both mission and spacecraft level. An overview of the spacecraft design down to subsystem level will then be presented (including the telescope and instruments), touching upon the critically-enabling technologies where appropriate. Finally, a programmatic overview will be given of the on-going Assessment Phase, and a snapshot of the prospects for securing the 'as-proposed' mission within the cost envelope will be given.

9601-20, Session 5

Fireball-2: a UV multi-object spectrograph for detecting the low z circumgalactic medium

D. Christopher Martin, Erika T. Hamden, California Institute of Technology (United States); David Schiminovich, Columbia Univ. (United States); Bruno Milliard, Robert Grange, Lab. d'Astrophysique de Marseille (France); Shouleh Nikzad, Jet Propulsion Lab. (United States); Lauren Corlies, Columbia Univ. (United States); Robert Crabill, California Institute of Technology (United States); Didier Ferrand, Lab. d'Astrophysique de Marseille (France); Albert Gomes, Ctr. National d'Études Spatiales (France); Anne-Sophie Hutter, Marc Jaquet, Lab. d'Astrophysique de Marseille (France); April Jewell, Jet Propulsion Lab. (United States); Gillian Kyne, California Institute of Technology (United States); Vincent Lamande, Gerard Lemaitre, Lab. d'Astrophysique de Marseille (France); Michele Limon, Columbia Univ. (United States); Nicole Lingner, California Institute of Technology (United States); Marc Llored, Lab. d'Astrophysique de Marseille (France); Mateusz Matuszewski, California Institute of Technology (United States); Pierre Mege, Lab. d'Astrophysique de Marseille (France); Frederi Mirc, Ctr. National d'Études Spatiales (France); Patrick Morrissey, California Institute of Technology (United States); Hwei Ru Ong, Columbia Univ. (United States); Alain Origne, Sandrine Pascal, Celine Peroux, Samuel Quiret, Didier Vibert, Lab. d'Astrophysique de Marseille (France); Jose M. Zorrilla, Columbia Univ. (United States)

The Faint Intergalactic Redshifted Emission Balloon (FIREBall-2) is a joint NASA/CNES collaboration that will launch in 2016. FIREBall-2 is a balloon-born ultraviolet (UV) multi-object spectrograph designed to detect faint emission from the circumgalactic medium (CGM) around low z galaxies. This emission is visible via a narrow atmospheric window (195-225 nm) accessible at balloon altitudes (40km). FIREBall-2 builds on the existing gondola and large optics of FIREBall-1, which launched in 2007 and 2009. The new spectrograph for FIREBall-2 has been extensively redesigned to improve performance by over an order of magnitude. To improve instrument throughput, a photon-counting delta-doped electron multiplying charge-coupled device (EMCCD) has replaced the Galaxy Evolution Explorer (GALEX) spare near-UV microchannel plate. Custom red blocking coatings minimize out-of-band light and improve in-band transmission. A set of field correcting optics has been added to increase the field of view, and a suite of slit masks yield up to 50 objects per field. Here we discuss the final flight design along with ongoing integration and testing in Marseille. We describe expected performance in flight, the detection limits we anticipate given our instrument model, and potential targets for our flight in 2016.

9601-21, Session 5

Detector performance for FIREBall's UV experiment

April D. Jewell, Jet Propulsion Lab. (United States); Erika T. Hamden, California Institute of Technology (United States); Timothy M. Goodsall, Charles A. Shapiro, Samuel R. Cheng, Todd J. Jones, Alexander G. Carver, Michael E. Hoenk, Jet Propulsion Lab. (United States); David Schiminovich, Columbia Univ. (United States); D. Christopher Martin, California Institute of Technology (United States); Shouleh Nikzad, Jet Propulsion Lab. (United States)

We present an overview of the detector for the upcoming Faint Intergalactic Red-shifted Emission Balloon (FIREBall-2) experiment, with a particular focus on the development of device-integrated optical coatings and detector quantum efficiency (QE). FIREBall-2 is designed to measure emission from the strong resonance lines of HI, OVI, and CIV, all red-shifted to 195-225 nm window; its detector is a delta-doped electron multiplying charge-coupled device (EM-CCD). Delta-doped arrays, invented at JPL, achieve 100% internal QE from the UV through the visible. External losses due to reflection (~70% in some UV regions) can be mitigated with antireflection (AR) coatings. Using atomic layer deposition (ALD) thin-film optical filters are incorporated with existing detector technologies. ALD offers nanometer-scale control over film thickness and interface quality, allowing for precision growth of multilayer films. Several AR coatings, including single and multi-layer designs, were tested for FIREBall-2. QE measurements match modeled transmittance behavior remarkably well, showing improved performance in the target wavelength range. Also under development are ALD coatings to enhance QE for a variety of spectral regions throughout the UV (90-320) and visible (320-1000 nm) range both for space-based imaging and spectroscopy as well as for ground-based telescopes.

9601-22, Session 5

Noise and dark performance for FIREBall-2 EMCCD delta-doped CCD detector

Erika T. Hamden, Nicole Lingner, Gillian Kyne, Patrick Morrissey, D. Christopher Martin, California Institute of Technology (United States)

The Faint Intergalactic Redshifted Emission Balloon (FIREBall-2) is an experiment designed to observe low-density emission from HI, CIV, and OVI in the circum-galactic medium (CGM) around low-redshift galaxies (z=0.3-1.0). To detect this diffuse emission, we have chosen to use a high-efficiency photon-counting EMCCD as part of FIREBall-2's detector system. The flight camera system includes a custom PC board, a mechanical cryo-cooler (stirling engine), zeolite and charcoal getters, and a NUVU controller, for fast read-out speeds. Here we report on overall detector system performance, including pressure and temperature stability. We describe our characterization of detector noise from a delta-doped, anti-reflection-coated, electron-multiplying e2v CCD201-20. We describe our use of a NUVU controller to create custom waveforms that reduce clock-induced charge (CIC). We detail the clock frequencies, waveform shapes, and well depths required to reduce parallel and serial CIC to acceptable levels for our application (~10-3 events/pix/frame), at a range of substrate voltages. We also describe dark current measurements at several temperatures, including at our operating temperature of -125°C, with the flight set-up. Finally, we examine the overall performance for photon counting and the expected signal to noise for this experiment.

9601-23, Session 5

Solar glint suppression in compact planetary ultraviolet spectrographs

Michael W. Davis, G. Randall Gladstone, Cesare Grava, Thomas K. Greathouse, Kurt D. Retherford, Southwest Research Institute (United States)

Solar glint suppression is an important consideration in the design of compact photon-counting ultraviolet spectrographs. Southwest Research Institute developed the Lyman Alpha Mapping Project for the Lunar Reconnaissance Orbiter (launch in 2009), and the Ultraviolet Spectrograph on Juno (Juno-UVS, launch in 2011). Both of these compact spectrographs revealed minor solar glints in flight that did not appear in pre-launch analyses. These glints only appeared when their respective spacecraft were operating outside primary science mission parameters. Post-facto scattered light analysis verifies the geometries at which these glints occurred and why they were not caught during ground testing or nominal mission operations. The limitations of standard baffle design at near-grazing angles are discussed, as well as the importance of including surface scatter properties in standard stray light analyses when determining solar keep-out regions. In particular, the scattered light analysis of these two instruments shows that standard "one bounce" assumptions in baffle design are not always enough to prevent scattered sunlight from reaching the instrument focal plane. Future builds, such as JUICE-UVS, will implement improved scattered and stray light modeling early in the design phase to enhance capabilities in extended mission science phases, as well as optimize solar keep out volume.

9601-24, Session 5

Characterizing, managing, and correcting distortions in the HST/COS FUV detector

David J. Sahnow, George Dana Becker, John H. Debes, Justin Ely, Sean A. Lockwood, Derck Massa, Cristina M. Oliveira, Steven V. Penton, Charles Proffitt, Julia Roman-Duval, Hugues Sana, Paule Sonnentrucker, Joanna Taylor, Space Telescope Science Institute (United States)

The Far Ultraviolet (FUV) detector on the Cosmic Origins Spectrograph (COS) of the Hubble Space Telescope (HST) is subject to a variety of distortions due to its analog nature. Thermal variations of the detector and electronics stretch and shift the active area. Geometric distortions on a range of spatial scales warp the two-dimensional spectral image. Changes to detector walk - the dependence of detected position on pulse height – add distortions that change as a function of time. The CalCOS calibration pipeline includes corrections for each of these effects in the calibrated spectra, but these are imperfect, and they do not help with the target acquisition process, which uses raw detector coordinates.

We discuss these distortions and their effect on the data, our attempts to mitigate them, the current pipeline corrections and their success at removing the effects, and possible improvements to improve the data quality in the future.

9601-25, Session 6

New UV instrumentation enabled by enhanced broadband lithium fluoride coatings

Brian T. Fleming, Univ. of Colorado at Boulder (United States); Manuel A. Quijada, NASA Goddard Space Flight Ctr. (United States); Kevin France, Univ. of Colorado at Boulder (United States)

We present the results of a preliminary aging study of new enhanced broadband reflectivity lithium fluoride mirror coatings under development at the thin films laboratory at GSFC. These coatings have demonstrated greater than 80% reflectivity from the Lyman ultraviolet (~1040 Angstroms) to the optical, and have the potential to revolutionize FUV instrument design and capabilities. This work is part of a concept study in preparation for the flight qualification of these new coatings in a working astronomical environment. We outline the timeline for TRL advancement, and discuss the FUV science enabled by these high reflectivity broadband coatings on proposed or planned space missions. We also present the early design of the first space experiment to utilize these coatings, the proposed University of Colorado sounding rocket payload SISTINE, and show how these new coatings make the science goals of SISTINE attainable on a suborbital platform.

9601-26, Session 6

Characterization of borosilicate microchannel plates functionalized by atomic layer deposition

Camden D. Ertley, Oswald H. W. Siegmund, Jason McPhate, Anton Tremsin, John V. Vallerga, Space Sciences Lab. (United States); Henry J. Frisch, The Univ. of Chicago (United States); Jeffrey W. Elam, Anil U. Mane, Robert G. Wagner, Argonne National Lab. (United States); Michael J. Minot, Aileen O'Mahony, Christoher A. Craven, Mark Popecki, Incom Inc. (United States)

Glass capillary arrays (GCAs) have been functionalized through Atomic Layer Deposition (ALD) to produce robust microchannel plates (MCPs) with improved performance characteristics over traditional MCPs. The GCA substrates, made from a Borosilicate glass, have many advantages over traditional MCP lead glass, including the ability to be fabricated in large areas (currently at 400 cm2). The Borosilicate substrates have a lower radioactive content, meaning a lower background, can withstand higher temperatures during processing, and have a low outgassing. Using ALD to functionalize the substrate decouples the two and provides the opportunity to explore many new materials. Preliminary results indicate that using an MgO secondary electron emitting layer could provide stable high gains (~1x104 @ 900V) for orders of magnitude longer than standard MCPs (5 C cm-2). Also in contrast to standard devices only a very short burn in period (<0.05 C cm-2 vs. 0.25 C cm-2) seems to be required, and the gain rises during this period.

9601-27, Session 6

Performance and characteristics of the FUV microchannel plate detector for icon

Oswald H. W. Siegmund, Jason McPhate, Nate Darling, Travis Curtis, Sharon R. Jelinsky, Univ. of California, Berkeley (United States)

No Abstract Available

9601-28, Session 6

Design and characterization of the ICON FUV CCD cameras

Erik Syrstad, Brian C. Thompson, Robert Burt, Mitch Whiteley, Space Dynamics Lab. (United States)

The Far Ultraviolet Imaging Spectrograph (FUV) on the upcoming Ionospheric Connection Explorer (ICON) mission uses dual image-intensified CCD camera systems, capable of detecting individual UV photons from both spectrometer channels (135.6 and 155 nm). Incident photons are converted to visible light using a sealed tube UV converter (described in an accompanying paper). The converter output is coupled to the CCD active area using a bonded fiber optic taper. The CCD (Teledyne DALSA FTT1010M) is a 1024x1024 frame transfer architecture. The camera readout electronics provide video imagery to the spacecraft over a 21 bit serialized LVDS interface, nominally at 10 frames per second and in 512x512 format (2x2 pixel binning). The CCD and primary electronics assembly reside in separate thermal zones, to minimize dark current without active cooling.

An engineering model camera system has been assembled, integrated, and tested. The CCD camera has been fully characterized with both visible light (prior to integration with the UV converter) and UV photons (following system integration). Measured parameters include camera dark current, read noise, linearity, gain, pulse height distribution, dynamic range, charge transfer efficiency, resolution, and full well capacity. Functional testing demonstrates that over a range of microchannel plate (MCP) voltages, camera performance will meet the critical FUV dynamic range requirements.

Flight model cameras will be fabricated and tested, followed by integration with the FUV instrument and sensor calibration in Summer 2015. Camera design and full performance data for the engineering and flight model cameras will be presented.

9601-29, Session PMon

A transmissive x-ray polarimeter conception for hard x-ray focusing telescopes

Hong Li, Hua Feng, Jianfeng Ji, Zhi Deng, Li He, Ming Zeng, Tenglin Li, Yinong Liu, Peiying Heng, Qiong Wu, Dong Han, Tsinghua Univ. (China); Yongwei Dong, Fangjun Lu, Shuangnan Zhang, Institute of High Energy Physics (China)

The X-ray Timing and Polarization (XTP) is a mission concept for a future space borne X-ray observatory and is currently selected for early phase study. We present a new design of X-ray polarimeter based on the time projection gas chamber. The polarimeter, placed above the focal plane, has an additional rear window that allows hard X-rays to penetrate (a transmission of nearly 80% at 6 keV) and reach the focal plane detector of focusing telescopes. Such a design is to compensate the low detection efficiency of gas detectors, at a negligible cost of sensitivity, and can maximize the science return of multilayer hard X-ray telescopes without the risk of moving focal plane instruments. The sensitivity in terms of minimum detectable polarization, based on current instrument configuration, is expected to be 3% for a 1mCrab source given an observing time of 10^5 s. We present preliminary test results, including photoelectron tracks and modulation curves, using a test chamber and polarized X-ray source in the lab.

9601-30, Session PMon

Characterization of single photon operation of Al0.8Ga0.2As Geiger photodiodes

Xiao Jie Chen, Erik B. Johnson, Chad M. Whitney, Radiation

Monitoring Devices, Inc. (United States); Min Ren, Yaojia Chen, Joe C. Campbell, Univ. of Virginia (United States); James F. Christian, Radiation Monitoring Devices, Inc. (United States)

Solid-state photomultipliers (SSPM) are high gain photodetectors composed of Geiger photodiodes (GPD) operating above device breakdown voltage. In scintillation based detection applications, SSPMs fabricated using silicon (SiPMs, MPPCs, etc) provide a compact, low cost alternative to photomultiplier tubes (PMTs), however, the high dark count rate due to its low band-gap (1.1eV) limits the signal-to-noise performance as the silicon SSPM is scaled to large areas. SSPMs fabricated in materials with a larger band-gap have the potential to surmount the performance limitations experienced by silicon. AlGaAs is a material that provides a bandgap from 1.55eV to 2.13 eV, depending on Al concentration. Using high Al concentration AlGaAs to engineer a wide-band-gap (>2eV) SSPM is very desirable in terms of reducing dark noise, which promises better signal-to-noise performances when large detector areas is needed.

This work describes the development of Geiger photodiodes (GPDs), the individual elements of a SSPM, fabricated in AlGaAs with 80% Al concentration. It presents the design of the GPDs, simulations of their performance, the fabrication process, along with characterization data of fabricated GPD samples. We show that with proper surface and sidewall passivation, high material quality, extremely low dark count rate GPD and SSPMs can be realized in this wide-band-gap material.

9601-31, Session PMon

Current progress in the characterization of atomic layer deposited metal fluorides for future astronomical ultraviolet mirror coatings

Christopher S. Moore, Univ. of Colorado at Boulder (United States); John Hennessy, April D. Jewell, Shouleh Nikzad, Jet Propulsion Lab. (United States); Kevin France, Univ. of Colorado at Boulder (United States)

Astronomical reflective aluminum (Al) mirrors are traditionally protected by a transmissive overcoat. The optical, mechanical and chemical properties of this overcoat material strongly effect the spectral reflective properties and durability of the mirror system. We are developing atomic layer deposited metal fluorides and assessing their applicability for future astronomical space missions in the ultraviolet and visible wavelengths. In this paper we present reflectance, environmental storage, surface roughness and chemical stability results.

9601-32, Session PMon

Silicon photomultipliers for next generation high-energy space telescopes

Karine Lacombe, Jürgen Knödlseder, Simon Delaigue, Maël Galliano, Baptiste Houret, Pascale Ramon, Gilbert Rouaix, Institut de Recherche en Astrophysique et Planétologie (France); Cédric Virmontois, Ctr. National d'Études Spatiales (France)

Photon detection is a central element of any high-energy astronomy instrumentation. One classical setup that has proven successful in many missions is the combination of photomultiplier tubes (PMTs) with scintillators, converting incoming high-energy photons into visible light, which in turn is converted in an electrical impulse. Although being extremely sensitive and rapid, PMTs have the drawback of being bulky, fragile, and requiring a high-voltage power supply of up to several thousand volts. Recent technological advances in the development of silicon photomultipliers (SiPM) make them a promising alternative to PMTs in essentially all their applications. We have started a R&D program to assess the possibility of using SiPMs for space-based applications in the domain of high-energy astronomy. We will present first results of our characterization studies of SiPMs from several manufacturers. Each SiPM has been tested inside a vacuum chamber and at low temperature to assess its performance in a space environment. After comparison, we will select a baseline detector with to design a dedicated front-end electronics and mechanical system. Furthermore, we plan to develop a specific low noise voltage power supply that ensures the stability of the SiPMs. Our ultimate goal is to qualify the system for a Technical Readiness Level of 5.

9601-33, Session PMon

VUV testing of science cameras at MSFC: QE measurement of the clasp flight cameras

Patrick R. Champey, The Univ. of Alabama in Huntsville (United States); Ken Kobayashi, Amy R. Winebarger, Jonathan W. Cirtain, David W. Hyde, Bryan A. Robertson, Brent L. Beabout, Dyana L. Beabout, NASA Marshall Space Flight Ctr. (United States); Mike Stewart, The Univ. of Alabama in Huntsville (United States)

The NASA Marshall Space Flight Center (MSFC) has developed a science camera suitable for sub-orbital missions for observations in the UV, EUV and soft X-ray. Six cameras were built and tested for the Chromospheric Lyman-Alpha Spectro-Polarimeter (CLASP), a joint National Astronomical Observatory of Japan (NAOJ) and MSFC sounding rocket mission. The CLASP camera design includes a frame-transfer e2v CCD57-10 512x512 detector, dual channel analog readout electronics and an internally mounted cold block. At the fight operating temperature of -20 C, the CLASP cameras achieved the low-noise performance requirements (≤25 e- read noise and ≤10 e-/sec/pixel dark current), in addition to maintaining a stable gain of -2.0 e-/DN. The e2v CCD57-10 detectors were coated with Lumogen-E to improve quantum efficiency (QE) at the Lyman-alpha wavelength. A vacuum ultraviolet (VUV) monochromator and a NIST calibrated photodiode were employed to measure the QE of each camera. Four fight-like cameras were tested in a high-vacuum chamber, which was configured to operate several tests intended to measure the QE, gain, read noise, dark current and residual non-linearity of the CCD. We present and discuss the QE measurements performed on the CLASP cameras. We also discuss the high-vacuum system outfitted for testing of UV and EUV science cameras at MSFC.

9601-35, Session PMon

The UV multi-object slit-spectrograph FireBALL-2 simulator

Pierre Mège, Sandrine Pascal, Samuel Quiret, Lab. d'Astrophysique de Marseille (France); Lauren Corlies, Columbia Univ. (United States); Didier Vibert, Robert Grange, Bruno Milliard, Lab. d'Astrophysique de Marseille (France)

The FIREBall-2 Instrument Model (FIREBallIMO) is a piece of software aiming at reproducing the optical behaviour of the Multi-Object Two-Curved Schmidt Slit Spectograph of FIREBall-2 (Faint Intergalactic Redshifted Emission BALLoon), a balloon-flight space mission (40 km in alt.) designed to perform a direct detection of the Circum Galactic Medium (CGM) in emission around low-z galaxies (c.f. 9601-20 conference). The spectrograph is optimized to operate in a narrow UV band [195-225] nanometers, the so-called the atmospheric sweet spot, where the sky background presents no emission lines and can be considered approximately flat, a value of 500 continnum units, seen through an optical transmission of a 50 at an atmospheric pressure of 3 millibars. This paper gives an overview of the software current modular architecture after a year of productive effort (in terms of parametric model space definition, associated data cubes and digital processing) from the instrument initial optical model designed under Zemax software to the final 2D-detected image. A special emphasis

is put on the design of a cython-wrapped driver able to retrieve dense ray-sampled PSFs out of the Zemax box efficiently. The optical mappings and distortions from the sky to the spectrograph entrance slit plane and from the sky to the detection plane are presented, as well as some end-to-end simulations leading to Signal-to-Noise Ratio estimates from artificial point-like or extended test sources.

Conference 9602: UV/Optical/IR Space Telescopes and Instruments: Innovative Technologies and Concepts VII

SPIE. OPTICS+ PHOTONICS OPTICAL ENGINEERING+ APPLICATIONS

Sunday - Monday 9 –10 August 2015

Part of Proceedings of SPIE Vol. 9602 UV/Optical/IR Space Telescopes and Instruments: Innovative Technologies and Concepts VII

9602-1, Session 1

The JWST science instrument payload: mission context and status

Matthew A Greenhouse, NASA Goddard Space Flight Ctr. (United States)

Status of the Integrated Science Instrument Module (ISIM) of the James Webb Space Telescope (JWST) is discussed from a systems perspective with emphasis on integration and test. The ISIM is the science instrument payload of the JWST and is one of three elements that comprise the JWST space vehicle. It is in the final stage of space simulation testing ahead of delivery for integration with the telescope at the end of this year.

9602-2, Session 1

Beyond JWST: a technology path to the next great UVOIR space telescope

David C. Redding, Jet Propulsion Lab. (United States); David Schiminovich, Columbia Univ. (United States); Sara Seager, Massachusetts Institute of Technology (United States); Julianne Dalcanton, Univ. of Washington (United States); Suzanne Aigrain, Oxford Univ. (United Kingdom); Steven J. Battel, Battel Engineering, Inc. (United States); Niel Brandt, The Pennsylvania State Univ. (United States); Charles Conroy, Univ. of California, Santa Cruz (United States); Lee D. Feinberg, NASA Goddard Space Flight Ctr. (United States); Suvi Gezari, Univ. of Maryland, College Park (United States); Olivier Guyon, Subaru Telescope, National Astronomical Observatory of Japan (United States); Walter Harris, The Univ. of Arizona (United States); Christopher M. Hirata, The Ohio State Univ. (United States); John C. Mather, NASA Goddard Space Flight Ctr. (United States); Marc Postman, Space Telescope Science Institute (United States); H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States); Jason Tumlinson, Space Telescope Science Institute (United States)

We report on the AURA “Beyond JWST” committee’s considerations and conclusions regarding technology paths for the development of a large UVOIR observatory, to be launched following JWST and WFIRST-AFTA. The ambitious science goals for this mission include the discovery and spectral characterization of exo-earth candidates; the study of galaxies and stellar populations at spatial resolutions of 100 parsec at any redshift in the UV and visible universe; and multi-object spectroscopy up to R of 50,000, especially in the UV, to probe the chemical evolution and gas kinematics in and around galaxies both near and far. Requirements for aperture size, starlight suppression efficiency, and sensitivity at Far-UV wavelengths, all present significant technology challenges – but challenges that are within reach, building incrementally on current NASA investments and progress within the community. WFIRST-AFTA is pioneering new methods for coronagraphs that work with obscured apertures – work that can be extended to include larger segmented apertures. Exoplanet Program investments in starshade technologies for smaller telescopes inform choices for larger apertures. Cosmic Origins Program and non-NASA investments in mirrors, coatings and detectors already enable a range of telescope and scientific instrument architectures. We will present the consensus recommendations of the AURA committee on both the current readiness levels of these key technologies and on the additional steps needed to support a viable flight concept for a future large UVOIR space telescope.

9602-3, Session 1

TECHBREAK: a technology foresight activity for the European Space Agency points the way to future space telescopes

Colin Cunningham, UK Astronomy Technology Ctr. (United Kingdom); Martin J. Cullum, European Southern Observatory (Germany); Emmanouil Detsis, European Science Foundation (France); Paul Kamoun, Thales Alenia Space (Belgium); Jean-Pierre Swings, Univ. de Liège (Belgium); Jean-Jacques Tortora, Eurospace (France); Jean-Claude Worms, European Science Foundation (France)

We report on a joint European Science Foundation-ESA “Forward Look” project called TECHBREAK aimed at identifying technological breakthroughs for space originating in the non-space sector. We show how some of the technologies highlighted may impact future space programmes, in particular novel ideas to enable future long-life large telescopes to be deployed. The goals of the study, which reported to ESA’s High level Science Policy Advisory Committee (HISPAC) in late 2014, were to forecast the development of breakthrough technologies to enable novel space missions in the 2030-2050 timeframe, and to identify related partnerships through synergies with non-space specialists. Rather than be a definitive guide for very specific technologies to be developed for future space missions, it aims to flag up the main developments in technological and scientific areas outside space that may hold promise for use in the space domain, by identifying the current status of research for each technology domain, asserting the development horizon for each technology and providing links to key European experts and institutions with knowledge. The identification of problems and solutions specific to the space area led to focus the discussion around the concept of “Overwhelming Drivers” for space research and exploration, i.e. long-term goals that can be transposed into technological development goals. Two of these drivers are directly relevant to ambitious future telescope projects, and we will show how some of the technologies we identified such as biomimetic structures, nanophotonics, novel materials and additive manufacturing could be combined to enable revolutionary new concepts for space telescopes.

9602-4, Session 1

A future large-aperture UVOIR space observatory: reference designs

Norman Rioux, Lee D. Feinberg, NASA Goddard Space Flight Ctr. (United States); David C. Redding, Jet Propulsion Lab. (United States); H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States)

Our joint NASA GSFC/JPL/MSFC/STScI study team has used community-provided science goals to derive mission needs, requirements, and candidate mission architectures for a future large-aperture UVOIR space observatory. Reference designs have been developed for non-cryogenic telescopes that span UVOIR wavelengths. We describe the assessment we are conducting on the requirements and feasibility of system thermal and dynamic stability for supporting coronagraphy. The observatory is in a Sun-Earth L2 orbit providing a stable thermal environment and excellent

field of regard. ATLAST has developed a reference design for a 36-segment 9.2 m aperture telescope that stows within a five meter diameter launch vehicle fairing. Compatibility with three different launch vehicles mitigates programmatic risk. A deployed, three-layer, flat stray light shield oriented perpendicular to the sun provides stray light protection and benefits thermal stability. The telescope and instruments are dynamically isolated from spacecraft disturbance sources and the secondary mirror is actively controlled. The team has also assessed an 11.2 m aperture that required a different method of deploying the secondary mirror support structure and has evaluated some on-orbit assembly options. Options for a monolithic primary mirror up to 8 meters in diameter are also in the trade space. The performance needs developed under the study are traceable to a variety of reference designs. The observatory reference concepts are designed to be serviceable for potential life extension and upgrades, but do not require servicing for mission success. The details of these reference designs will be presented.

9602-5, Session 1

SLS launched missions concept studies for LUVOIR Mission

H. Philip Stahl, Randall Hopkins, NASA Marshall Space Flight Ctr. (United States)

The "Enduring Quests Daring Visions: NASA Astrophysics in the Next Three Decades" report calls for a Large UV-Optical-IR (LUVOIR) Surveyor mission to enable ultra-high-contrast spectroscopic and coronagraphic studies. A key technical challenge is how to get a 'large' telescope into space. The JWST design was severely constrained by the mass and volume capacities of its launch vehicle. Using an SLS (Space Launch System) rocket with its 10-m diameter x 30-m tall fairing and 45 mt payload to SE-L2, allows considerable design margin. This paper reports on concept studies of missions launch using an SLS (Space Launch System) rocket.

9602-6, Session 1

An evolvable space telescope for future astronomical missions: 2015 update

Ronald S. Polidan, Northrop Grumman Aerospace Systems (United States); James B. Breckinridge, Breckinridge Associates, LLC (United States); Charles F. Lillie, Lillie Consulting, LLC (United States); Howard A. MacEwen, Reviresco LLC (United States); Martin R. Flannery, Dean R. Dailey, Northrop Grumman Aerospace Systems (United States)

Astronomical flagship missions after the James Webb Space Telescope (JWST) will require lower cost space telescopes and science instruments. Innovative spacecraft-electro-opto-mechanical system architectures matched to the science requirements are needed for observations for exoplanet characterization, cosmology, dark energy, galactic evolution formation of stars and planets, and many other research areas. The needs and requirements to perform this science will continue to drive us toward larger and larger apertures.

Recent technology developments in precision station keeping of spacecraft, interplanetary transfer orbits, wavefront/sensing and control, laser engineering, macroscopic application of nano-technology, lossless optical designs, deployed structures, thermal management, interferometry, detectors and signal processing enable innovative telescope/system architectures with break-through performance.

Unfortunately, NASA's budget for Astrophysics is unlikely to be able to support the funding required for the 8-m to 16-m telescopes that have been studied for the follow-on to JWST using similar development/assembly approaches without accounting for too large of a portion of the Astrophysics Division's budget. Consequently, we have been examining the feasibility of developing an "Evolvable Space Telescope" that would be 3 to 4-m when placed on orbit and then periodically augmented with additional mirror segments, structures, and newer instruments to evolve the telescope and achieve the performance of a 16-m space telescope.

This paper provides an update to the 2014 SPIE paper discussing the technologies required for such a mission, candidate architecture approaches, and discusses different science measurement objectives for the stages of the architectures.

9602-7, Session 2

Overview and accomplishments of advanced mirror technology development phase 2 (AMTD-2) project

H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States)

The Advance Mirror Technology Development (AMTD) project is a multi-year effort initiated in FY12 to mature technologies required to enable 4 to 8 meter (or larger) UVOIR space telescope primary mirror assemblies for both general astrophysics and ultra-high contrast observations of exoplanets. AMTD Phase 1 completed all of its goals and accomplished all of its milestones. AMTD Phase 2 started in 2014. Key accomplishments include deriving primary mirror engineering specifications from science requirements; developing integrated modeling tools and using those tools to perform parametric design trades; and demonstrating new mirror technologies via sub-scale fabrication and test. AMTD-1 demonstrated the stacked core technique by making a 43-cm diameter 400 mm thick 'biscuit-cut' of a 4-m class mirror. AMTD-2 is demonstrating lateral scalability of the stacked core method by making a 1.5 meter 1/3rd scale model of a 4-m class mirror.

9602-8, Session 2

Technology development for the Advanced Technology Large Aperture Space Telescope (ATLAST) as a candidate large UV-Optical-Infrared (LUVOIR) surveyor

Matthew R. Bolcar, NASA Goddard Space Flight Ctr. (United States); Kunji Balasubramanian, Jet Propulsion Lab. (United States); Mark Clampin, Julie A. Crooke, Lee D. Feinberg, NASA Goddard Space Flight Ctr. (United States); Marc Postman, Space Telescope Science Institute (United States); Manuel A. Quijada, Bernard J. Rauscher, NASA Goddard Space Flight Ctr. (United States); David C. Redding, Jet Propulsion Lab. (United States); Norman Rioux, NASA Goddard Space Flight Ctr. (United States); Stuart B. Shaklan, Jet Propulsion Lab. (United States); H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States); Carl M. Stahle, Harley A. Thronson Jr., NASA Goddard Space Flight Ctr. (United States)

We have identified six key technologies that will enable the Advanced Technology Large Aperture Space Telescope (ATLAST), a candidate architecture for the future large-aperture ultraviolet/optical/infrared (LUVOIR) space observatory envisioned by the NASA Astrophysics 30-year roadmap, "Enduring Quests, Daring Visions". The science goals of ATLAST address a broad range of astrophysical questions from early galaxy and star formation to the processes that contributed to the formation of life on Earth, combining general astrophysics with direct-imaging and spectroscopy of habitable exoplanets. The key technologies are: starlight suppression systems, lightweight mirrors, sensing and control systems, ultra-stable structures, detectors, and mirror coatings. Selected technology performance goals include: 1x10^-10 raw contrast at an inner working angle of 35 mas, wavefront error stability of 10 pm per 10 minutes, autonomous on-board sensing & control, and zero read noise photon-counting detectors spanning wavelengths from 300 nm to 1.8 μm. Development of these technologies

will provide significant advances over current and planned observatories in terms of sensitivity, angular resolution, stability, and high-contrast imaging. The science goals of ATLAST are presented and flowed down to top-level telescope and instrument performance requirements in the context of a reference architecture: a 10 meter class, segmented aperture telescope operating at room temperature (~290 K) at the sun-Earth L2 point. For each technology area, we define best estimates of required capabilities, current state-of-the-art performance, and current Technology Readiness Level (TRL) – thus identifying the current technology gap. We report on current, planned, or recommended efforts to develop each technology to TRL 5.

9602-9, Session 2

ATLAST ULE mirror segment performance analytical predictions based on thermally induced distortions

Michael J. Eisenhower, Lester M. Cohen, Smithsonian Astrophysical Observatory (United States); Lee D. Feinberg, NASA Goddard Space Flight Ctr. (United States); Gary W. Matthews, Exelis Inc. (United States); Joel A. Nissen, Jet Propulsion Lab. (United States); Sang C. Park, Smithsonian Astrophysical Observatory (United States); Hume L. Peabody, NASA Goddard Space Flight Ctr. (United States)

The Advanced Technology Large-Aperture Space Telescope (ATLAST) is a concept for a 9.2 m aperture space-borne observatory operating across the UV/Optical/NIR spectra. The primary mirror for ATLAST is a segmented architecture with pico-meter class wavefront stability. Due to its extraordinarily low coefficient of thermal expansion a leading candidate for the primary mirror substrate is Corning's ULE® titania-silicate glass. The ATLAST ULE® mirror substrates will be maintained at 'room temperature' during on orbit flight operations minimizing the need for compensation of mirror deformation between the manufacturing temperature and the operational temperatures. This approach requires active thermal management to maintain operational temperature while on orbit. Furthermore, the active thermal control must be sufficiently stable to prevent time-varying thermally induced distortions in the mirror substrates. This paper describes a conceptual thermal management system for the ATLAST 9.2m segmented mirror architecture that maintains the surface distortion to less than 10 pico-meters/10 minutes RMS. Thermal and finite-element models, analytical techniques, accuracies involved in solving the mirror figure errors, and early findings from the thermal and thermal-distortion analyses are presented.

9602-10, Session 2

Correction of large aperture active space telescope mirror using a gradient approach and a secondary deformable mirror

Matthew R. Allen, Jae Jun Kim, Brij N. Agrawal, Naval Postgraduate School (United States)

High development cost is a challenge for space telescopes and imaging satellites. One of the primary reasons for this high cost is the development of the primary mirror, which is required to meet diffraction limit surface figure requirements. Recent efforts have been made to develop lower cost, lightweight, replicable primary mirrors to include SiC actuated hybrid mirrors and carbon fiber mirrors. The SiC and carbon fiber mirrors at the Naval Postgraduate School do not meet the surface quality required for an optical telescope due to high spatial frequency residual surface errors. A technique under investigation at the Naval Postgraduate School is to correct the residue surface figure error by incorporating a deformable mirror in the optical path. This approach could result in significant reduction in development cost of the primary mirror by reducing surface figure requirements and provide an on orbit correction capability.

The Naval Postgraduate School's Segmented Mirror Telescope (SMT) test bed uses 1-meter silicon carbide (SiC) active mirror segments to form a six-segment deployable 3-meter telescope. The active segments suffer from residual surface figure errors after a correction is applied. This research adds an additional deformable mirror to the optical path and uses a single closed loop adaptive gradient feedback controller to actively control the SMT segment and the secondary deformable mirror. The SMT segment surface figure error is characterized and a closed loop adaptive gradient controller is demonstrated by simulation and experiment. Simulation and experimental results are presented.

9602-11, Session 2

Optical design of camera for transiting exoplanet survey satellite (TESS)

Michael Chrisp, Kristin E. Clark, Brian C. Primeau, Michael Dalpiaz, Joseph Lennon, MIT Lincoln Lab. (United States)

This paper covers the design of a wide field of view refractive camera system, one of four identical cameras which form the TESS scientific payload. Photometry performed by these cameras requires maximum light gathering power, so the optical design was optimized to provide the fastest f-number (f/1.4) given the volume and weight available for the cameras. The cameras are designed with no vignetting, unlike most fast lens systems. The final design evolved from a starting Petzval design form, and has seven lenses, two of which have aspheric surfaces. This design was developed to make maximum use of the correction of the aspheric surfaces. The resulting design has an intermediate pair of negative lenses lessening the field curvature needed to be corrected by the field lens group. Forbes aspheres were used during the optimization process, with search methods used to establish which surfaces the two aspheres should be placed on for maximum performance improvement. Interestingly, these were better than those from CODEV's asphere expert module. The aspheres in the design reduce the average spot size by 60% compared with an all spherical design. The tolerancing of the system is described together with the current tolerance set, which shows the feasibility of building the system.

9602-12, Session 2

Detector requirements for coronagraphic biosignature characterization

Bernard J. Rauscher, NASA Goddard Space Flight Ctr. (United States)

Are we alone? Answering this ageless question, by searching for habitable worlds, will be a major focus for astrophysics in the 2020s. Our primary tools will be unprecedentedly powerful UV-Optical-IR space telescopes coupled with coronagraphs and/or starshades. Yet, these incredible facilities will not accomplish their objectives without better detectors than we have today.

Biosignature gases include oxygen, ozone, water vapor, and methane. Other non-biological gases, including carbon monoxide and carbon dioxide, can discriminate false positives. All imprint spectroscopic features in the UV-Optical-IR that can be characterized at low spectral resolution, R > 70, to constrain atmospheric chemistry and determine the likelihood of biological processes.

Even assuming an observatory like the Large UV-Optical-IR (LUVOIR) Surveyor described in NASA's "Enduring Quests Daring Visions" 30-year roadmap and recently recommended to NASA by the "BJWST" study, the detector requirements are beyond today's state-of-the-art. Essentially noiseless detection from the UV through at least near-IR is required with QE >~ 80%. At the expected ~0.003 photon/s/pix flux, likely requirements include read noise << 1 e-, dark current <~ 0.0003 e-/s, and negligible noise from other instrumental sources. Moreover, the detectors must withstand the rigors of space including the L2 radiation environment for a notional >~ 5 yrs.

To inform detector development, we provide a broad overview of the detector requirements, and their scientific rationale, for spectroscopic characterization of atmospheric biosignature gasses using a LUVOIR. Where existing detector technologies are close to meeting requirements, we comment on where improvement would be most beneficial.

9602-13, Session 3

Orbiting rainbows: NIAC phase II progress

Scott A. Basinger, Marco B. Quadrelli, Jet Propulsion Lab. (United States); Grover A. Swartzlander Jr., Xiaopeng Peng, Rochester Institute of Technology (United States); Alexandra Artusio, Rochester State Rocks (United States); Darmin D. Arumugam, Jet Propulsion Lab. (United States)

"Orbiting Rainbows" is a Phase II NASA Innovative Advanced Concepts (NIAC) study that is looking twenty years into the future of creating a space-based observatory from granular media. "Granular matter" is considered to be the fifth state of matter; this investigation draws from recent research on disordered lenses and turbid lens imaging. The investigators are performing fundamental research and developing the technology roadmap to construct an optical system in space using nonlinear optical properties of a cloud of micron-sized particles, shaped into a specific surface by light pressure, to form a very large and lightweight aperture of an optical system. This "cloud optic" will be relatively simple to package, transport, and deploy. It is reconfigurable and can be re-targeted; the focal length is variable and it will be self-healing and ultimately disposable. The concept, in which the aperture does not need to be continuous and monolithic, will allow the aperture size to be several times larger than currently envisioned observatories such as ATLAST and a fraction of the mass and cost. The ultimate cloud optic could be several tens of meters in diameter, and multiple clouds can be combined to create kilometer-class apertures. The concept also relies heavily on computational optics to deconvolve objects from non-deal imagery. Simulations and experiments have been positive using speckle interferometry techniques together with blind image deconvolution using a sparse, specular media for a primary mirror of an optical system. This talk will give a brief overview of the Orbiting Rainbows concept and presents ground-based subscale experimental results.

9602-15, Session 3

Design and test of the new generation solar imaging telescope

Olha V. Asmolova, Geoff Andersen, U.S. Air Force Academy (United States)

We describe imaging capabilities of a 0.2 m membrane diffractive primary (DOE) used as a key element in FalconSat-7, a space-based solar telescope. Its mission is to take an image of the Sun at the H-alpha wavelength (656nm) over a narrow bandwidth while in orbit. In this case the DOE is a photon sieve which consists of billions of tiny holes, with the focusing ability dependent on an underlying Fresnel zone geometry. Uniform radial expansion/contraction of the substrate due to temperature or relative humidity change will result in a shift in focal length without introducing errors in phase of the transmitted wavefront and without a decrease in efficiency. We will also show that while ideally the DOE surface should be held flat to within 5.25 microns, an opto-mechanical analysis showed that local deformations up to 32 microns are possible without significantly degrading the image quality.

9602-17, Session 4

Characterization of Euclid-like H2RG IR detectors for the NISP instrument

Benoît Serra, Aurélia Secroun, Anne Ealet, Jean Claude Clémens, Philippe Lagier, Mathieu Niclas, Ctr. de Physique des Particules de Marseille (France); remi Barbier, Eric Chabanat, Bogna Kubik, Institut de Physique Nucléaire de Lyon (France); Michael I. Andersen, Niels Bohr Institute (Denmark); Thierry Maciaszek, Lab. d'Astrophysique de Marseille (France); Anton Norup Sørensen, Niels Bohr Institute (Denmark); Eric Prieto, Lab. d'Astrophysique de Marseille (France); Gérard Smadja, Institut de Physique Nucléaire de Lyon (France)

The success of the Euclid's NISP (Near-Infrared Spectro-Photometer) survey requires very high performance detectors for which tight specifications have been defined. These must be verified over more than 95% of the focal plane: typically a dark current lower than 0.07 e-/s, a total noise lower than 13 e- in spectroscopic mode and 9 e- in photometric mode or a persistence signal lower than 0.05e-/s after 5 hours. The detectors are a procurement of ESA under a contract of NASA who will deliver to us selected flight detectors under Euclid specifications. 16 of Teledyne's 2.3 μm cutoff 2048x2048 pixels H2RG infrared detectors will fill the NISP focal plane and must be fully characterized at the pixel level: this is CPPM's responsibility.

This characterization is crucial to the future processing and in-flight calibration and may be quite challenging: for instance, measuring very low level dark currents – as low as 10^{-3} e-/s – or persistence signals, which implies alternating dark current measurements with flat field strong illumination. This has led to the definition of a thorough test plan and to the development of dedicated facilities, analysis methods and software tools. First tests of high performance engineering grade detectors show the quality of our characterization chain and will be presented, including dark current, total noise, both CDS and science modes, conversion gain and persistence. A pilot run is foreseen at the end of the year to validate the test plan. Next step will be the characterization of flight detectors expected to start in Spring 2016.

9602-18, Session 4

Preliminary results on the EUCLID NISP stray-light and ghost analysis

Frank U. Grupp, Univ.-Sternwarte München (Germany) and Max-Planck-Institut für extraterrestrische Physik (Germany); Norbert Geis, Ralf Bender, Max-Planck-Institut für extraterrestrische Physik (Germany)

No Abstract Available

9602-19, Session 5

Coatings for UVOIR telescope mirrors

Kunjithapatham Balasubramanian, John Hennessy, Shouleh Nikzad, Nasrat A. Raouf, Michael E. Ayala, Jet Propulsion Lab. (United States); Javier G. Del Hoyo, Manuel A. Quijada, NASA Goddard Space Flight Ctr. (United States)

NASA Cosmic Origins Program initiatives call for large telescope architectures with high throughput from far UV to near IR to enable efficient gathering of light with important spectral signatures including those in far UV region down to 90nm. Typical Aluminum mirrors protected with MgF2 fall short of the requirements below 120nm. Therefore new and improved coatings are sought to protect aluminum from oxidation that causes severe absorption. Besides choice of materials, the process of applying coatings has to be optimized and controlled accurately and reliably to ensure the coatings preserve the expected optical characteristics. This challenge is addressed here with experimental investigations at JPL and at GSFC. We present the progress achieved to date and discuss the path forward to achieve 90% reflectance in the spectral region from 90 to 130nm without degrading performance in the visible and NIR regions taking into account durability concerns when the mirrors are exposed to normal laboratory conditions.

9602-20, Session 5

Carbon nanotube optical mirrors

Peter C. Chen, NASA Goddard Space Flight Ctr. (United States) and The Catholic Univ. of America (United States); Douglas M. Rabin, NASA Goddard Space Flight Ctr. (United States)

We report the fabrication of imaging quality optical mirrors with smooth and super-smooth surfaces using carbon nanotubes (CNT) embedded in an epoxy matrix. CNT/epoxy is a multifunctional composite material that has sensing capabilities and can be made to incorporate self-actuation. As the precursor is a low density liquid, large and lightweight mirrors can be fabricated by non-traditional processes such as replication, spincasting, and additive manufacturing. With the infusion of advanced numerical modeling techniques such as topology optimization and state of the art 3D printing, CNT/E technology is a promising candidate for the development of a new generation of lightweight, compact "smart" telescope mirrors and structures with figure sensing, active optics, adaptive optics, athermal construction, and in-space fabrication capabilities. We report on measurements made of optical and mechanical characteristics, active optics experiments, and numerical modeling. We discuss possible paths for future development.

9602-21, Session 5

A global shutter CMOS image sensor with in-pixel CDS for hyperspectral imaging

Ben J. Dryer, Konstantin D. Stefanov, David J. Hall, The Open Univ. (United Kingdom); Jérôme Pratlong, Martin Fryer, Andrew Pike, e2v technologies plc (United Kingdom)

Hyperspectral imaging has been providing vital information on the Earth landscape in response to the changing environment, land use and natural phenomena. While conventional hyperspectral imaging instruments have typically used rows of linescan CCDs, CMOS imaging sensors (CIS) have been slowly penetrating space instrumentation for the past decade, and Earth Observation (EO) is no exception. CIS provide distinct advantages over CCDs that are relevant to EO hyperspectral imaging. The lack of charge transfer through the array allows the reduction of cross talk usually present in CCDs due to imperfect charge transfer efficiency, and random pixel addressing makes variable integration time possible, and thus improves the camera sensitivity and dynamic range.

e2v technologies has developed a 10T pixel design that integrates a pinned photodiode with global shutter (to reduce blurring of the 'broom') and in-pixel CDS to increase the signal to noise ratio in less intense spectral regimes, allowing for both high resolution and low noise hyperspectral imaging for EO. This paper details the characterisation of a test device, providing baseline performance measurements of the array such as noise, responsivity, dark current and global shutter efficiency, and also discussing benchmark hyperspectral imaging requirements such as dynamic range, pixel crosstalk, and image lag.

9602-22, Session 5

Testing simple models for dynamic correlated charge collection effects in thick CCDs

Daniel P. Weatherill, Konstantin D. Stefanov, Andrew D. Holland, The Open Univ. (United Kingdom); Douglas Jordan, e2v technologies plc (United Kingdom); Ivan V. Kotov, Brookhaven National Lab. (United States)

The subject of dynamic charge collection effects in thick CCDs has received great interest in recent years, due to the major performance and calibration consequences implied for precision optical astronomy, in both ground-based (e.g. LSST) and space-based (e.g. EUCLID) missions. These phenomena are observed as both the "brighter - fatter" effect, causing measured asymmetry in the PSF of a CCD, and as statistical correlations visible in the photon transfer curve and spatial autocorrelation measurements of the device.

It is widely accepted that the dynamic effects are caused due to the changing geometry and magnitude of the electric fields in the pixels as the collecting potential wells are filled. Several models have been proposed based on this which are able to calculate ancillary pixel data to aid in correcting for the effect in device calibration and data reduction.

In this paper we present validation results using flat-field calibration data from an e2v CCD250 for a simple model, based on analytical solutions of the Poisson equation. The model is not intended to provide detailed correction data for a specific device, but as an estimator for predicting sensor performance based on design parameters.

9602-23, Session 5

Proton-induced random telegraph signal in the CMOS imaging sensor for JANUS, the visible imaging telescope on JUICE

George P. Winstone, Matthew R. Soman, Andrew D. Holland, Jason P. D. Gow, Konstantin D. Stefanov, Mark Leese, The Open Univ. (United Kingdom)

JUpiter ICy moons Explorer (JUICE) is an ESA L class mission due for launch in 2022 as part of the agency's Cosmic Vision program. The primary science goal is to explore and characterise Jupiter and several of its potentially habitable icy moons, particularly Ganymede, Europa and Callisto.

The JANUS instrument is designated to be the scientific imager on-board the spacecraft with a wavelength range between 400 nm and 1000 nm and consists of a catoptric telescope coupled to a CMOS detector, specifically the CIS115 monolithic active pixel sensor supplied by e2v technologies. A CMOS sensor has been chosen due to a combination of the high radiation tolerance required for all systems aboard the spacecraft and its capability of operating with integration times as low as 1 ms, which is required to prevent blur when imaging the moons at fast ground velocities since the camera has no mechanical shutter. However, an important consideration of using CMOS in high radiation environments is the generation of defects or defect clusters that result in pixels exhibiting Random Telegraph Signal (RTS).

A study of RTS effects in the CIS115 has been undertaken, and the method applied to identify pixels in the array that display RTS behaviour is discussed and individual RTS exhibiting pixels are characterised. The changes observed in RTS behaviour following irradiation of the CIS115 with protons will be presented and the temperature dependence of the RTS behaviour is studied. The implications on the camera design and imaging requirements of the mission are examined.

9602-24, Session 5

Radiation qualification of the CIS115 for the JUICE mission

Matthew Soman, Andrew D. Holland, George P. Winstone, Jason P. D. Gow, Konstantin D. Stefanov, Mark Leese, The Open Univ. (United Kingdom)

The CIS115 is one of the latest CMOS Imaging Sensors designed by e2v technologies, with 1504x2000 pixels on a 7 μm pitch. Each pixel in the array is a pinned photodiode with a 4T architecture, achieving an average dark current of 22 electrons/pixel/s at 21°C. The sensor aims for high optical sensitivity by utilising e2v's back-thinning and processing capabilities, providing a sensitive silicon thickness approximately 9 μm to 12 μm thick with a tuned anti-reflective coating.

The sensor operates in a rolling shutter mode incorporating reset level subtraction resulting in a mean pixel readout noise of 4.25 electrons rms.

The full well has been measured to be 34000 electrons, resulting in a dynamic range of up to 8000. These performance characteristics have led to the CIS115 being chosen for JANUS, the high-resolution and wide angle optical camera on the JUpiter ICy moon Explorer (JUICE).

The three year science phase of JUICE is in the harsh radiation environment of the Jovian magnetosphere, primarily studying Jupiter and its icy moons. Analysis of the expected radiation environment and shielding levels from the spacecraft and instrument design predict the End of Life (EOL) displacement and ionising damage for the CIS115 to be equivalent to 10^10 10 MeV protons cm^-2 and 100 krad(Si) respectively. Characterisation results following proton and gamma irradiations will be presented, detailing the initial phase of space qualification of the CIS115. Results will be compared to the pre-irradiation performance and the instrument specifications and further qualification plans will be outlined.

9602-36, Session 5

A low noise, high QE, large format CCD camera system for the MIGHTI instrument on the NASA ICON mission

Jed J. Hancock, Joel G. Cardon, Michael Watson, Space Dynamics Lab. (United States); James Cook, Utah State Univ. (United States); Mitch Whiteley, James Beukers, Space Dynamics Lab. (United States); Christoph R. Englert, Charles M. Brown, U.S. Naval Research Lab. (United States); John M. Harlander, St. Cloud State Univ. (United States); Stewart E. Harris, Univ. of California, Berkeley (United States)

The Michelson Interferometer for Global High-resolution Thermospheric Imaging (MIGHTI) instrument is part of the NASA Ionospheric Connection Explorer (ICON) mission designed to uncover the mysteries of the extreme variability of the Earth's ionosphere. MIGHTI consists of two identical units positioned to observe the Earth's low latitude thermosphere from perpendicular viewing directions. The MIGHTI instrument is a spatial heterodyne spectrometer and requires a low noise, high QE, large format camera system to detect slight phase changes in the fringe patterns which reveal the neutral wind velocity.

The MIGHTI camera system uses a single control electronics box to operate two identical CCD camera heads and communicate with the ICON Instrument Control Package (ICP) electronics. The control electronics are carefully designed for a low noise implementation of CCD biases, clocking, and CCD output digitization. The camera heads use a 2k by 2K, back-illuminated, frame transfer CCD provided by e2v. The CCD's are both TEC cooled and have butcher-block interference filters mounted in close proximity to the active area. The CCDs are nominally operated in binned mode, the control electronics register-settings provide flexibility for binning and gain control. An engineering model of the camera system has been assembled and tested. The EM camera system characterization meets all performance requirements. Performance highlights include a measured read noise of 5.7 electrons and dark current of less than 0.01 electrons/pixel/second. The camera system design and characterization results are discussed.

9602-25, Session 6

Optical design and tolerance analysis of a reflecting telescope for CubeSat

Ching-Wei Chen, Chia-Ray Chen, National Space Organization (Taiwan)

Optical design of a small reflecting telescope for use in a 3U CubeSat mission is reported in this study. The off-axis segmented method for earth observation techniques based on a Ritchey-Chrétien type telescope is adopted in this design. The primary mirror and secondary mirror are circular apertures with 70-mm and 22-mm in diameter. The effective focal length is 685-mm operated at 450-km altitude. A commercial 1928 ? 1084 CCD image sensor with a pixel size of 7.4-?m ? 7.4-?m is applied, which capture a 9.2-km ? 5.3-km swath area. The ground resolution is moderate to be 4.86-m for CubeSat application. The MTF is expected to be about 0.4 at camera resolution at 67.6-lp/mm. The tolerance analysis is performed for further understanding on fabrication and assembly errors. This telescope shows a reasonable design to obtain a more detailed image with a CubeSat. These results will be used in space exploration with CubeSat missions.

9602-26, Session 6

Analysis of an optical relay system and integration into a satellite imager

Louahab Noui, Surrey Satellite Technology Ltd. (United Kingdom)

A description of an optical relay subsystem used in a high resolution earth observation satellite imager is presented. Tolerance and thermal analysis showed that very tight tolerances are required to achieve diffraction limited performance. The tolerancing methodology of the optical system is described and compared to the actual build process. Alignment of optical elements is critical for the successful build of the relay system, and ground support equipment was developed for this purpose. The alignment technique and verification of the build of different components are presented. Typical results of the alignment process together with predicted performance are reported.

Optical characterisation of the relay subsystem in terms of wavefront analysis is described and it is shown that some tolerances were not practically achievable. To achieve diffraction limited performance an optical correction method was developed and implemented. The description of the methodology adopted to measure the optical performance of the relay system and to calculate the corresponding wavefront correction is discussed. The implementation of free-form surface figuring is also presented. The successful practical implementation of wavefront correction to achieve diffraction limited space telescope system is demonstrated.

9602-27, Session 6

Focal plane actuation for the development of a high resolution suborbital telescope

Alexander D. Miller, Paul A. Scowen, Arizona State Univ. (United States); Todd J. Veach, NASA Goddard Space Flight Ctr. (United States)

We present a hexapod stabilized focal plane as the key instrument for a proposed suborbital balloon mission. Balloon gondolas currently achieve 1-2 arcsecond pointing error, but cannot correct for unavoidable jitter movements (~50 microns at 20hz) caused by wind rushing over balloon surfaces, thermal variations, cryocoolers, and reaction wheels. The jitter causes image blur during exposures and is the limiting resolution of the system. To solve this, the hexapod system actuates the focal plane to counteract the jitter through real-time closed loop feedback from star-trackers. Removal of this final jitter term decreases pointing error by an order of magnitude and allows for true diffraction-limited observation. This boost in resolution will allow for Hubble-quality imaging for a fraction of the cost. Tip-tilt pointing systems have been used for these purposes in the past, but require additional optics and introduce multiple reflections. The hexapod system, rather, is compact and can be plugged into the focal point of nearly any configuration. The design also thermally isolates the hexapod from the cryogenic focal plane enabling the use of well-established non-cryogenic hexapod technology.

High-resolution time domain multispectral imaging of the gas giant outer planets, especially in the UV range, is of particular interest to the planetary community, and a suborbital telescope with the hexapod stabilization in place would provide a wealth of new data. On an Antarctic ~100-day Long-Duration-Balloon mission the continued high-resolution imaging of gas giant storm systems would provide cloud formation and evolution data second to only a Flagship orbiter.

9602-28, Session 6

Low cost visible imaging and IR spectroscopy from stratospheric telescopes

Eliot F. Young, Southwest Research Institute (United States); Charles A. Hibbitts, Andrew F. Cheng, Johns Hopkins Univ. Applied Physics Lab., LLC (United States); Robert A. Woodruff, Lockheed Martin Corp. (United States)

NASA's Balloon Office regularly supports missions in which stratospheric telescopes make observations from altitudes of 33 - 38 km, above 99.3% - 99.6% of the Earth's atmosphere. These missions are much cheaper than spacecraft missions while providing two key advantages over ground-based facilities: the potential for diffraction-limited imaging in UV-visible wavelengths and nearly complete access to the infrared spectrum.

The BOPPS mission (Balloon Observation Platform for Planetary Science) flew 0.8-m telescope on September 25, 2014 for a 20-hour flight. BOPPS carried an infrared camera (0.8-5 μm) to image targets that are normally obscured from the ground by telluric species and a guide camera/fast steering mirror to stabilize the focal plane at the sub-0.1" level.

Prospects for upcoming balloon missions are promising: NASA is testing large super-pressure balloons for 100-day circumglobal flights. These missions will nominally provide 1000 hours of dark-time from a near-space environment, comparable to the ~3000 hours that HST awards annually to science observations. Furthermore, several recent payloads (including BOPPS) have stabilized telescopes at the level of a few arc seconds or better, with fine steering systems able to maintain pointing at the diffraction limit. Finally, recent work suggests that passive thermal shielding can lower telescope temperatures to less than 180 K to reduce thermal self-emission below the sky background levels from 1 - 4.8 microns.

These capabilities potentially make scientific balloon platforms as productive as space telescopes for certain science applications, but with distinct advantages such as low cost, re-usability and short timescales from proposal to flight.

9602-30, Session 7

Thermal shield with high soft x-ray transparency

Bruce M. Lairson, Heidi Lopez, David Grove, Travis Ayers, Luxel Corp. (United States)

Thermal shields are required for cryogenic sensors, cooled imaging arrays, and the interior of spacecraft. We present a hybrid metal grid/metal membrane with improved blocking of thermal infrared photons, with high EUV and soft X-ray transmittance. In some cases, infrared blocking can be 10X higher for the hybrid structure compared with superposition of separate membranes and grids. We present infrared thermal shielding of grid-supported freestanding aluminum membranes between 15nm and 50nm thick, as well as membranes supported by both a grid and by ultrathin polyimide.

9602-31, Session 7

Challenges in photon-starved space astronomy in a harsh radiation environment using CCDs

David J. Hall, Nathan L. Bush, Neil J. Murray, Jason P. D. Gow, Andrew S. Clarke, Ross Burgon, Andrew D. Holland, The Open Univ. (United Kingdom)

The Charge Coupled Device (CCD) has a long heritage for imaging and spectroscopy in many space astronomy missions. However, the harsh radiation environment experienced in orbit creates defects in the silicon that capture the signal being transferred through the CCD. This radiation damage has a detrimental impact on the detector performance and requires carefully planned mitigation strategies.

The ESA Gaia mission uses 106 CCDs, now orbiting around the second Lagrange point as part of the largest focal-plane ever launched. Following readout, signal electrons will be affected by the traps generated in the devices from the radiation environment and this degradation will be corrected for using a charge distortion model. ESA's Euclid mission will also contain a focal plane of CCDs in the VIS instrument. Moving further forwards, the World Space Observatory (WSO) UV spectrographs and the WFIRST-AFTA coronagraph intend to look at very faint sources in which mitigating the impact of traps on the transfer of single electron signals will be of great interest.

Following the development of novel experimental and analysis techniques, one is now able to study the impact of radiation on the detector to new levels of detail. Through a combination of TCAD simulations, defect studies and device testing, we are now probing the interaction of single electrons with individual radiation-induced traps to analyse the impact of radiation in photon-starved applications.

9602-32, Session 7

Optical tolerancing and predicted performance of the Wide-Field InfraRed Survey Telescope / Astrophysics Focused Telescope Assets (WFIRST/AFTA) wide-field instrument

Bert A. Pasquale, Catherine T. Marx, David A. Content, Jeffrey W. Kruk, Qian Gong, Joseph M. Howard, Alden S. Jurling, J. Eric Mentzell, NASA Goddard Space Flight Ctr. (United States); Nerses V. Armani, Arthur L. Whipple, Martina S. Atanassova, Cliffton E. Jackson, SGT, Inc. (United States); Thomas M. Casey, Sigma Space Corp. (United States); Carl A. Blaurock, Nightsky Systems, Inc. (United States)

The optical design of the Wide-Field InfraRed Survey Telescope (WFIRST) Wide-Field Channel (WFC) continues to evolve through design and analysis cycles. While the as-designed performance has been discussed in previous publications, ultimately it is the as-built on-orbit performance that must satisfy the scientific requirements. The 2.37-meter diameter (Hubble-Class) aperture Three Mirror Anastigmat (TMA) -based optical design has been analyzed for fabrication, alignment, and stability budgets. We have taken into account the Integration and Testing (I&T) plan, Integrated Modeling (IM) and Structural / Thermal / Optical (STOP) analysis. The WFC is predicted to maintain diffraction-limited performance over a focal plane of 300 million pixels. Its instantaneous field of view coverage of 0.282 degrees at 0.11 arcsecond pixel scale will operates in six panchromatic bands between 0.7 – 2.0μm, or in spectrographic imaging mode from 1.35-1.95μm.

9602-33, Session 7

Wide-Field InfraRed Survey Telescope/ Astrophysics Focused Telescope Assets (WFIRST/AFTA) grism spectrometer

Qian Gong, NASA Goddard Space Flight Ctr. (United States); Thomas Casey, Sigma Space Corp. (United States); David A. Content, Margaret Z. Dominguez, Jeffrey W. Kruk, Catherine Marx, Bert A. Pasquale, Thomas E. Wallace, Arthur O. Whipple, NASA Goddard Space Flight Ctr. (United States)

The Grism spectrometer plays an important role in WFIRST/AFTA mission for the survey of emission-line galaxies. This presentation discusses the challenges and solutions of the optical design, as well as its potential to further expand the wavelength range and accommodate any Field Of View (FOV) change for future design cycles. However, the emphasis of this presentation is the progress of the grism prototype: the design, fabrication, and test of the complicated diffractive optical elements and powered prism and current status. It also addresses the cryogenic test plan: to test the designed infrared diffractive elements using a visible interferometer and to test whole grism assembly using phase retrieval at the designed wavelength range. Finally, the optical alignment, tolerance, and mechanical design will be discussed.

9602-34, Session 7

Spectral performance of WFIRST/AFTA bandpass filter prototypes

Manuel A. Quijada, David A. Content, Jeffrey W. Kruk, Kevin H. Miller, NASA Goddard Space Flight Ctr. (United States)

The current pre-formulation baseline for the Wide Field Infrared Survey Telescope Astrophysics Focused Telescope Assets (WFIRST/AFTA) consists of a single wide field channel instrument with 0.28 deg2 active field of view for both imaging and spectroscopy. The only routinely moving part during scientific observations for this wide field channel is the element wheel (EW) assembly. This filter wheel assembly will have 8 positions that will be populated with 6 different bandpass coatings, a blank position, and a Grism that will consist of 3 element assembly that disperses with the central wavelength undeviated for galaxy redshift surveys. All elements in the EW assembly will have ~110 mm diameter fused silica substrates that will have the appropriate band-pass coatings according to the filter designations (Z087, Y106, J129, H158, F184, W149 and Grism). This paper will present and discuss spectral performance (including spectral transmission and surface figure wavefront errors) for a subset of the band-pass coatings for the filter types Z087, W149, and Grism. These filter coatings have been procured from three different vendors to address the most challenging aspects in terms of the in-band throughput (>95%), Out of band rejection (<10^E-05), uniformity (< 1% transmission level) and the cut-on and cut-off slopes (3% for the filters and 0.3% for the Grism coatings).

9602-16, Session PMon

Demonstrator model: a first demonstration of the NISP detection system

Jean Claude Clémens, Aurélia Secroun, Benoît Serra, Anne Ealet, Ctr. de Physique des Particules de Marseille (France); Rémi Barbier, Institut de Physique Nucléaire de Lyon (France); Florent Beaumont, Lab. d'Astrophysique de Marseille (France); Eric Chabanat, Institut de Physique Nucléaire de Lyon (France); Christophe Fabron, José Garcia, Emmanuel Grassi, Lab. d'Astrophysique de Marseille (France); Bogna Kubik, Institut de Physique Nucléaire de Lyon (France); Thierry Maciaszek, Eric Prieto, Lab. d'Astrophysique de Marseille (France); Gérard Smadja, Institut de Physique Nucléaire de Lyon (France)

CPPM is in charge of the characterization and integration into the focal plane of EUCLID's NISP (Near-Infrared Spectro-Photometer) 2.3 μm cutoff 2048 x 2048 pixel H2RG infrared detectors. NISP's focal plane array (FPA) contains a matrix of 16 detectors acquired simultaneously. Before delivering the full instrument to ESA after the detectors characterization, several test models will have to demonstrate the performances of the detector system.

The first test model, the Demonstrator Model (DM), has been integrated at LAM and tested in dedicated facilities. The aim was to validate both the integration process and the simultaneous acquisition of four detectors and their EMC behavior. In order to validate the science acquisition modes, a series of dark measurements has been acquired to assess the stability and the good performances of the detectors. Dark levels down to 10^-2 electrons/second were measured without using a dark lid onto the FPA. Dark current peak-to-peak oscillations at the level of 3.10^-2 were observed for acquisitions of 560s and confirmed later on. Moreover noise studies in various acquisition configurations showed that total noise is quite independent of the configuration.

Measurements and analysis done using the data acquired during the DM tests will be described. In addition, a study on cosmic ray impact on detectors has been conducted and initial results will be shown. Tests and data will be used for next sessions of test models that will come before the delivery of the NISP instrument to ESA in 2017.

9602-35, Session PMon

ACCESS: integration and pre-launch performance

Mary E. Kaiser, Matthew J. Morris, Johns Hopkins Univ. (United States); Jeffrey W. Kruk, Bernard J. Rauscher, Randy A. Kimble, NASA Goddard Space Flight Ctr. (United States); Edward L. Wright, Univ. of California, Los Angeles (United States); Stephan R. McCandliss, Russell Pelton, Lauren N. Aldoroty, Grant O. Peacock, Paul D. Feldman, Henry W. Moos, Johns Hopkins Univ. (United States); Adam G. Riess, Johns Hopkins Univ. (United States) and Space Telescope Science Institute (United States); Dominic J. Benford, Jonathan P. Gardner, NASA Goddard Space Flight Ctr. (United States); Ralph C. Bohlin, Susana E. Deustua, William V. Dixon, David J. Sahnow, Space Telescope Science Institute (United States); Robert Kurucz, Harvard-Smithsonian Ctr. for Astrophysics (United States); Michael Lampton, Space Sciences Lab. (United States); Saul Perlmutter, Lawrence Berkeley National Lab. (United States)

ACCESS, Absolute Color Calibration Experiment for Standard Stars, is a series of rocket-borne sub-orbital missions and ground-based experiments that will leverage the significant technological advances in detectors, instruments, and the precision of the fundamental laboratory standards used to calibrate these instruments to enable improvements in the precision of the astrophysical flux scale through the transfer of absolute laboratory detector standards from the National Institute of Standards and Technology (NIST) to a network of stellar standards with a calibration accuracy of 1% and a spectral resolving power of 500 across the 0.35 to 1.7 micron bandpass.

Achieving a calibration accuracy of 1% precision is important for understanding scientific phenomena such as dark energy where a reduction in the cross-color calibration systematic errors associated with SNeIa photometry is needed to distinguish between dark energy models

The ACCESS Cassegrain telescope feeds a compact (Rowland circle design) spectrograph with a cross dispersing Fery prism and HST/WFC3 heritage 1024x1024 HgCdTe detector. The telescope, spectrograph, and avionics system are currently being fabricated, assembled, and integrated. Sub-system testing of flight components is ongoing. Detector characterization is in progress. Flight software is under test. The detector telemetry interface has been written and stand-alone tested. Thermal vacuum testing of the detector, controller and flight computer has been successful.

Integration and test results will be presented in addition to the calibration strategy and status. Launch is expected within the year. NASA sounding rocket grant NNX08AI65G supports this work.

9603-59, Session PMon

Coarse alignment of thin-shell, segmented mirrors for Wolter telescopes

Benjamin D. Donovan, The Univ. of Iowa (United States); Edward Hertz, Vanessa Marquez, Stuart McMuldroch, Paul B. Reid, Ryan Allured, Harvard-Smithsonian Ctr. for Astrophysics (United States)

The alignment of thin-shell, segmented mirrors for Wolter I telescopes frequently involves the use of a Hartmann test. In order to get optical throughput in the Hartmann test, the mirrors must first be coarsely aligned to one another and to the entire optical system. In the past, the coarse alignment of these mirrors at the Smithsonian Astrophysical Observatory has largely relied upon component machine tolerances and contact measurements with a coordinate measurement machine (CMM). This process takes time and does not produce reliable, nor repeatable results. Thus, methods were developed to allow for the quick and reliable coarse alignment of thin-shell, segmented mirrors, with the mirrors supported at their final locations in the mirror assembly. We present the coarse alignment system developed at the Smithsonian Astrophysical Observatory and its use in the alignment of thin-shell, segmented mirrors for the adjustable X-ray optics program.

9603-60, Session PMon

Addressing the problem of glass thickness variation in the indirect slumping technology

Laura Proserpio, Elias Breunig, Peter Friedrich, Anita Winter, Max-Planck-Institut für extraterrestrische Physik (Germany); Christoph Wellnhofer, Max-Planck-Institut für extraterrestrische Physik (Germany) and Institut für Werkstoffwissenschaft und Werkstoffmechanik (Germany)

The indirect hot slumping technology is being developed at Max-Planck-Institute for extraterrestrial Physics (MPE) for the manufacturing of lightweight astronomical X-ray telescopes. To obtain mirror segments of high optical quality, the optimization of the slumping thermal cycle itself is of fundamental importance, but also the starting materials, primarily the mould and the glass foils, play a major role. This paper will review the MPE latest results in the slumping technology and will then concentrate on the selection of the initial glass, with particular regards to the problem of glass foils thickness variation.

9603-61, Session PMon

Off-plane x-ray diffraction grating fabrication

Thomas J. Peterson, Casey T. DeRoo, Randall L. McEntaffer, The Univ. of Iowa (United States)

High performance X-ray diffraction gratings are essential for achieving key astrophysical science goals. Off-plane X-ray diffraction gratings with precision groove profiles at the submicron scale are necessary for next generation X-ray spectrometers. Such gratings will be used on a current NASA suborbital rocket mission, the Off-plane Grating Rocket Experiment (OGRE), and have application for future grating missions. The fabrication of these gratings does not come without challenges. High performance off-plane gratings must be fabricated with precise radial grating patterns, optically flat surfaces, and specific facet angles. Such gratings can be made using a series of common microfabrication techniques. First, the radial groove pattern is written into a resist/Cr coated fused silica plate using e-beam lithography. The pattern is then transferred into a silicon wafer using DUV immersion lithography and subsequent reactive ion etching. Creating the angled facets involves nanoimprinting the grating pattern onto a Si wafer of specific crystallographic orientation that has been nitride coated, followed by reactive ion etching through the nitride. An anisotropic chemical wet etch is then employed to form blazed triangular facets. This pattern is then replicated into a resist-coated fused silica substrate, which is optically flat, and UV cured. This process is highly customizable, making it useful for different mission architectures, as well as capable of low surface roughness over the grating facets, which is ideal for X-ray Spectrometers.

9603-62, Session PMon

Design and implementation of an x-ray reflectometer system for testing x-ray optics coatings

Danielle Gurgew, The Univ. of Alabama in Huntsville (United States) and NASA Marshall Space Flight Ctr. (United States); Brian D. Ramsey, Mikhail V. Gubarev, David Broadway, NASA Marshall Space Flight Ctr. (United States)

We have developed an X-ray reflectometer (XRR) system for the characterization of various soft and hard X-ray optic coatings being developed at Marshall Space Flight Center. The XRR system generates X-ray radiation with a high-output Rigaku rotating anode source (RAS), operational at a voltage range of 5 – 40 kV, a current range of 10-450 mA. A series of precision slits, adjustable down to approximately 20 micrometers, positioned in the beam path limit the extent of the x-ray beam and control the resolution of the XRR measurement while a goniometer consisting of two precision rotary stages controls the angular position of the coating sample and X-ray detector with respect to the beam. With the high count rate capability of the RAS, a very-high-speed silicon drift detector, the Amptek Fast SDD, is implemented to achieve good count rate efficiency and improve reflectivity measurements of coatings at larger graze angles. The coating sample can be adjusted using a series of linear and tipping stages to perfectly align the center of the sample with the center of the incident X-ray beam. These stages in conjunction with the goniometer components are integrated through original control software resulting in full automation of the XRR system. We will show some initial XRR measurements of both single and multilayer coatings made with this system. These results and future measurements are used to characterize potential X-ray optic coatings culminating in the production of highly reflective coatings operational at a large range of X-ray energies.

9603-63, Session PMon

The development of a deflectometer for accurate surface figure metrology

Mikhail V. Gubarev, Brian Ramsey, NASA Marshall Space Flight Ctr. (United States); Carolyn Atkins, The Univ. of Alabama in Huntsville (United States)

With the recent introduction of optical surface error correction methods, such as differential deposition and smart optics, the availability of in situ surface figure metrology methods becomes crucial for the development of the high-resolution, optics needed for future Astrophysics Missions. A surface-figure-metrology instrument based on an optical deflectometer scheme is under development at the Marshall Space Flight Center (MSFC). This presentation will detail the current status of the program and the expected capability of the instrument.

9603-64, Session PMon

Development of an x-ray telescope with a large effective area for the iron K line band

Hironori Matsumoto, Sasagu Tachibana, Shun Yoshikawa, Keisuke Tamura, Hideyuki Mori, Kojun Yamashita, Ikuyuki Mitsuishi, Yuzuru Tawara, Hideyo Kunieda, Nagoya Univ. (Japan)

X-ray micro-calorimeters such as the Soft X-ray Spectrometer (SXS) on board ASTRO-H will enable precise spectroscopy of iron K lines even for spatially extended objects. To exploit the full power of the high-energy resolution, X-ray telescopes with a large effective area around 6 keV are essentially important. Conventional X-ray telescopes aimed at X-rays below 10 keV have used the principle of total reflection to collect the X-rays. Enlarging the diameter of this type of telescopes is not effective to obtain the large effective area, since the incident angle of X-rays for the outer part of the telescope exceeds the critical angle and few X-rays are reflected from the outer part of the telescope. Therefore we are developing a multi-layer mirror to enhance the effective area at around 6 keV by using Bragg reflection. We assumed that the diameter of our telescope is 110 cm and the focal length is 6 m, which can be launched by the epsilon rocket of ISAS/JAXA. When the mirror surface is covered with a multi-layer of Ir/C, our simulation suggests that the effective area averaged in the 5.7--7.7 keV band could be 2000 cm2. This area is comparable to the effective area of Athena, which will be launched in 2028 by European Space Agency (ESA).

9603-65, Session PMon

Development of an x-ray telescope using the carbon fiber reinforced plastic

Hironori Matsumoto, Toshihiro Iwase, Masato Maejima, Nagoya Univ. (Japan); Hisamitsu Awaki, Ehime Univ. (Japan); Hideyo Kunieda, Nagoya Univ. (Japan); Naoki Ishida, Tamagawa Engineering Co., Ltd. (Japan); Satoshi Sugita, Ehime Univ. (Japan); Takuya Miyazawa, Naoki Shima, Ikuyuki Mitsuishi, Yuzuru Tawara, Nagoya Univ. (Japan)

Conventional X-ray telescopes utilize the Wolter-I optics which consist of parabolic mirrors followed by hyperbolic mirrors. X-ray telescopes on board Japanese satellites such as ASTRO-H have used many thin-foil mirrors to obtain large aperture efficiency and a large effective area. However, the mirrors are conically approximated. Moreover,

it is difficult to keep the shape of mirrors good and the mirrors are conically approximated. Therefore the angular resolution of this type of telescope has been limited. We are developing an X-ray mirror using the carbon fiber reinforced plastic (CFRP) as substrate in order to improve the angular resolution; the CFRP has a high strength-to-weight ratio and can be used to realize the quadratic surface of the Wolter-I optics. We have fabricated the reflection surface of Pt on the CFRP substrate by the epoxy-replication method by which we made the Hard X-ray Telescope of the ASTRO-H. We found that curing the epoxy at the room temperature is effective to suppress the print through. We were able to make mirrors whose shape accuracy is 3—5 um and roughness is ~4A. Characterization at the synchrotron facility SPring-8 using the X-ray pencil beam of 20 keV showed that the angular resolution was 3—5 arcmin as a whole, but can reach to 20 arcsec locally.

9603-1, Session 1

An overview on mirrors for Cherenkov telescopes manufactured by glass cold-shaping technology

Rodolfo Canestrari, INAF - Osservatorio Astronomico di Brera (Italy); Enrico Giro, INAF - Osservatorio Astronomico di Padova (Italy); Giacomo Bonnoli, Giuseppe Crimi, INAF - Osservatorio Astronomico di Brera (Italy); Mauro Fiorini, INAF - Istituto di Astrofisica Spaziale e Fisica Cosmica di Palermo (Italy); Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy); Gabriele Rodeghiero, INAF - Osservatorio Astronomico di Padova (Italy); Giorgia Sironi, INAF - Osservatorio Astronomico di Brera (Italy)

The cold glass-slumping technique is a low cost processing developed at INAF-Osservatorio Astronomico di Brera (INAF-OAB) for the manufacturing of mirrors for Cherenkov telescopes. This technology is based on the shaping of thin glass foils by means of bending at room temperature. The glass foils are thus assembled into a sandwich structure for retaining the imposed shape by the use of a honeycomb core. These mirrors employ commercial of-the-shelf materials thus allowing a competitive cost and production time. They show very low weight, rigidity and environmental robustness.

In this paper we give an overview on the most recent results achieved from the adoption of the cold-shaping technology to different projects of Cherenkov telescopes. We show the variety of optical shapes implemented ranging from those spherical with long radius of curvature up to the most curved free form ones.

9603-2, Session 1

The ASTRI SST-2M prototype for the Cherenkov Telescope Array: opto-mechanical test results

Rodolfo Canestrari, INAF - Osservatorio Astronomico di Brera (Italy); Enrico Giro, Gabriele Rodeghiero, INAF - Osservatorio Astronomico di Padova (Italy); Giorgia Sironi, INAF - Osservatorio Astronomico di Brera (Italy)

The Cherenkov Telescope Array (CTA) observatory, with a combination of large-, medium-, and small-scale telescopes (LST, MST, SST, respectively), will represent the next generation of Imaging Atmospheric Cherenkov Telescopes. It will explore the Very High Energy domain from a few tens of GeV up to few hundreds of TeV with unprecedented sensitivity, angular resolution and imaging quality.

In this framework, the Italian ASTRI program, led by the Italian National Institute of Astrophysics (INAF), is currently developing a scientific and technological SST prototype named ASTRI SST-2M. It is a 4-meter class telescope; it adopts an aplanatic, wide-field, double-reflection optical layout in a Schwarzschild-Couder configuration.

In this contribution we report about the on-site erection and the latest results on the opto-mechanical performance test conducted soon after the telescope installation.

9603-3, Session 1

ASTRI primary mirrors characterization by deflectometry

Giorgia Sironi, Rodolfo Canestrari, INAF - Osservatorio Astronomico di Brera (Italy)

In 2014 the Italian National Institute for Astrophysics for the ASTRI collaboration realized an end-to-end Cherenkov dual mirror prototypal telescope and installed it at Serra La Nave (Italy). In this project the Brera Astronomical Observatory was in charge for the primary mirror realization and testing. The ASTRI telescope primary mirror has an aperture of ~ 4 mm, a polynomial design and is tasselled in 18 hexagons. These characteristics lead to necessity of realize and test panels with a typical size of ~1 m and with an aspheric component up to millimeters.

The manufacturing of the segments was performed by assembling sandwich

of thin glass foils bended at room temperature to reach the desired shape. While for the characterization we realized an ad-hoc deflectometry facility than works as an inverse Ronchi interacting with a ray-tracing.

In this paper we report the results of the deflectometry metrological campaign realized on the primary mirror segments of the ASTRI dual mirror telescope. The expected PSF and the contributions to the image quality degradation are studied.

9603-4, Session 1

Towards the construction of a medium size prototype Schwarzschild-Couder telescope for CTA

Julien Rousselle, Univ. of California, Los Angeles (United States)

The US members of the Cherenkov Telescope Array (CTA) consortium will start the construction of a 10-m prototype Schwarzschild-Couder telescope (pSCT) in summer 2015 at the Fred Lawrence Whipple Observatory in Southern Arizona.

Compared to traditional Davies-Cotton telescopes, this novel instrument with aplanatic two-mirror optical system will offer a wider field-of-view and improved angular resolution. In addition, the reduced plate scale at the camera allows the use of highly-integrated photon detectors such as silicon photo multipliers. As part of CTA, this design has the potential to greatly improve the performance of the next generation ground-based observatory for very high-energy (E>100 GeV) gamma-ray astronomy.

In this contribution we present the final design of the optical system and optical support structure, as well as the telescope assembly and construction plan.

9603-5, Session 1

Results and developments from the 12m Davies-Cotton MST prototype for CTA

Louise Oakes, Humboldt-Univ. zu Berlin (Germany); Markus Garczarcyk, Stefan Schlenstedt, DESY Zeuthen (Germany); Ullrich Schwanke, Humboldt-Univ. zu Berlin (Germany)

The Cherenkov Telescope Array (CTA) will be the next generation ground-based observatory for gamma-ray astronomy, covering an energy range from a few tens of GeV to a few hundred TeV. The CTA project is currently in the design and prototyping phase, the start of construction is planned for 2016. The planned sensitivity of CTA improves on current ground based Cherenkov telescope experiments by about an order of magnitude. In the core energy range this sensitivity will be dominated by up to 40 Medium-Sized Telescopes. These telescopes, of a modified Davies-Cotton mount type with a reflector diameter of 12 m, are currently being prototyped.

A full-size mechanical prototype MST has been operating in Berlin since 2012. Several types of prototype mirrors have been developed and tested, and are mounted on the telescope. CCD cameras with various lenses are mounted on the prototype for studying deformation of the structure, testing alignment techniques, and telescope pointing using astrometry methods. The report will focus on results of more than two years of optical and structural measurements, commissioning and testing of the MST prototype in Berlin, as well as the final design plans for the Davies-Cotton MSTs for CTA.

9603-6, Session 1

Roughness tolerances for Cherenkov telescope mirrors

Kashmira Tayabaly, INAF - Osservatorio Astronomico di Brera (Italy) and Politecnico di Milano (Italy); Daniele Spiga, Giacomo Bonnoli, Rodolfo Canestrari, Giorgia Sironi, Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

The Cherenkov Telescope Array (CTA) is a forthcoming international ground-based observatory for very high-energy gamma rays. Its goal is to reach sensitivity five to ten times better than existing Cherenkov telescopes such as VERITAS, H.E.S.S. or MAGIC and extend the range of observation to energies down to few tens of GeV and beyond 100 TeV. To achieve this goal, an array of about 100 telescopes is required, meaning a total reflective surface of several thousands of m2. Thence, the optimal technology used for CTA mirrors' manufacture should be both low-cost (~1000euros/m2) and allow high optical performances over a [300nm-600nm] wavelength range: a reflectivity higher than 85% and a PSF diameter smaller than 1mrad. Surface roughness can significantly contribute to PSF broadening and limit telescope performances; but, it can also be easily controlled during mirrors' manufacturing so that surface roughness does not dominate other sources of scatter (surface defects, dust particles deposition,...). This paper determines first order surface finish tolerances based on a surface microroughness characterization campaign, using Phase Shift Interferometry. That allows us to compute the roughness contribution to Cherenkov telescope's point spread function. This study is performed for diverse mirror candidates (MAGIC-I and II, ASTRI, MST and FACT) varying in manufacture technologies, selected materials and taking into account the degradation over time due to environmental hazards.

9603-7, Session 2

Hard x-rays broad band Laue lenses (80 - 600 keV): building methods and performances

Enrico Virgilli, Filippo Frontera, Piero Rosati, Vittore Carassiti, Univ. degli Studi di Ferrara (Italy); Stefano Squerzanti, Istituto Nazionale di Fisica Nucleare (Italy); Ezio Caroli, John Stephen, Natalia Auricchio, Angelo Basili, Stefano Silvestri, INAF - IASF Bologna (Italy); Ferdinando Cassese, Luca Recanatesi, DTM Srl (Italy)

Soft gamma-ray astrophysics (> 80 keV) is expected to undergo a big leap ahead thanks to the introduction of focusing instruments replacing the currently used direct-view telescopes. Thanks to the technological progress of the last years, Laue lenses appear to be good candidates to fulfill such a role, considerably improving both the sensitivity and the angular resolution with respect to the conventional non-focusing instruments.

With the final goal of building a 20 m focal length Laue lens (80-600 keV), in the framework of the LAUE project, a set of bent crystals are being properly oriented and positioned on a lens petal frame, to focus radiation from 100 to 300 keV. Before bent crystals have never been used for this purpose, and we expect a great enhancement in terms of point spread function with respect to the flat mosaic crystals. We expect to present for the first time the energy response of the lens petal prototype and the achieved accuracy thanks to the adopted mounting method. We will also compare the measured results with the theoretical expectations both in laboratory with a divergent beam and in the case of parallel beam as that expected in space operation.

9603-8, Session 2

Rapid and accurate assembly method for a new Laue lens prototype

Colin Wade, Univ. College Dublin (Ireland); Nicolas M. Barrière, cosine Research B.V. (Netherlands); Lorraine Hanlon, Univ. College Dublin (Ireland); Steven E. Boggs, Space Sciences Lab. (United States); Nicolai F. Brejnholt, Lawrence Livermore National Lab. (United States); Sonny Massahi, Univ. of California, Berkeley (United States); John

A. Tomsick, Space Sciences Lab. (United States); Peter von Ballmoos, Institut de Recherche en Astrophysique et Planétologie (France)

The Laue lens is a technology for gamma-ray astrophysics whereby gamma-rays of particular energies can be brought to a focus by a suitable arrangement of crystals. The Laue lens assembly station at UC Berkeley was used to build a technological demonstrator addressing the key questions of crystal mounting speed, crystal position and orientation accuracy, and crystal reflectivity. The new prototype is a lens segment containing a total of 48 5x5mm2 crystals - 36 Iron and 12 Aluminium. The segment is composed of 8 partial rings, each of which is aligned to diffract an energy between 95 and 130 keV.

The system now in place demonstrates that a technique to quickly and accurately construct a Laue lens is now well established. The use of glue that cures under UV exposure has reduced the time needed to fix a crystal by a factor of ~200 compared to previous iterations. With this improvement, constructing a full lens with hundreds or even thousands of crystals becomes a far more achievable goal. This represents a great leap forward for Laue lens construction. Preliminary results are presented which demonstrate the performance of the system using the new assembly method.

9603-9, Session 2

Bending of crystals using carbon fiber films

Vincenzo Guidi, Riccardo Camattari, Valerio Bellucci, Gianfranco Paternò, Andrea Mazzolari, Enrico Virgilli, Univ. degli Studi di Ferrara (Italy)

Bent crystals are used or planned to be used in modern physics experiments based on coherent interactions of particles or e.m. radiation with crystals, such as for steering charged-particle beams and for focusing hard X-rays and soft ?-rays. Bent crystals are capable of deflecting X-rays through Bragg diffraction at high efficiency and with high-focusing power. For this reason, self-standing bent crystals are considered good candidates as optical elements for an X-ray concentrator, e.g. for a Laue lens. Thick crystals may be desirable because the efficiency of a Laue lens is proportional to the crystal thickness. Moreover, using large crystals implies that a relatively small number of samples is required for filling the lens. However, manufacturing of self-standing bent thick crystals is not simple, and the maximum thickness obtainable with several techniques does not exceed 2 mm. Recently, a method involving the use of carbon fiber as a tensile film was developed to manufacture self-standing bent samples up to 5 mm thick, with the curvature being homogeneous and suitable for X-ray diffraction. The samples have been manufactured as part of the INFN-LOGOS project, in collaboration with the Sensor and Semiconductor Laboratory, Ferrara (Italy) and RI-BA Composites, Faenza (Italy). The bent crystals were characterized with hard X-rays at ESRF and ILL, Grenoble (France). Further tests are being planned at LARIX, Ferrara (Italy). Here we report in details the procedure for realizing bent and quasi-mosaic crystals using carbon fiber as a tensile film, the film thickness being up to some hundreds of microns.

9603-10, Session 2

Development of self-focusing Si Laue components (SiLCs) for high performance Laue lenses

Nicolas M. Barrière, cosine Research B.V. (Netherlands) and Univ. of California, Berkeley (United States); Abdelhakim Chatbi, Maximilien Collon, Ramses Guenther, cosine Research B.V. (Netherlands); Lorraine Hanlon, Univ. College Dublin (Ireland); Giuseppe Vacanti, Mark Vervest, cosine Research B.V. (Netherlands); Peter von Ballmoos, Institut de Recherche en Astrophysique et Planétologie (France); Colin Wade, Univ. College Dublin (Ireland); Alexei Yanson, cosine Research B.V. (Netherlands)

In the soft gamma-ray domain, a Laue lens telescope could efficiently complement wide field of view instruments (like a compact Compton telescope for instance) by providing enhanced sensitivity and angular resolution in a selection of relatively narrow energy bands. The observation of nuclear decay lines from supernovae, novae or supernovae remnants, the study of the hard tails from compact objects are areas for which a Laue lens telescope would provide unmatched performance.

Cosine, in collaboration with the University of California at Berkeley, has been developing Silicon Laue Components (SiLCs): curved stacks of wedged crystalline Si plates held together by direct Si bonding, resulting in self-standing diffracting elements that focus both radially and azimuthally. These elements can be assembled into a high performance Laue lens, where for the first time, the size of the point spread function is decoupled from the size of the diffracting elements. A synchrotron run at the APS validated the concept and provided data to refine models. In this talk, we will present the development status of SiLCs, and refined estimates of the performance they could deliver.

9603-11, Session 3

Status of ART-XC / SRG instrument

Mikhail N. Pavlinsky, Valeriy Akimov, Vasiliy Levin, Igor Lapshov, Alexey Tkachenko, Nikolay Semena, Mikhail Buntov, Alexander Glushenko, Vadim Arefiev, Alexander Yaskovich, Space Research Institute (Russian Federation); Rashid Sunyaev, Eugene Churazov, Marat Gilfanov, Space Research Institute (Russian Federation) and Max-Planck-Institut für Astrophysik (Germany); Sergei Grebenev, Sergey Sazonov, Mikhail Revnivtsev, Alexander Lutovinov, Sergey Molkov, Mikhail Kudelin, Tatyana Drozdova, Space Research Institute (Russian Federation); Sergey Garanin, Sergey Grigorovich, Dmitriy Litvin, Valeriy Lazarchuk, Igor Roiz, Mikhail Garin, Russian Federal Nuclear Ctr. - All-Russian Research Institute of Experimental Physics (Russian Federation); Vladimir Babyshkin, Ilya Lomakin, Alexander Menderov, NPO Lavochkin (Russian Federation); Mikhail Gubarev, Brian Ramsey, Kiranmayee Kilaru, Stephen O'Dell, Jeffery Kolodziejczak, Ronald Elsner, NASA Marshall Space Flight Ctr. (United States)

Spectrum Roentgen Gamma (SRG) is an X-ray astrophysical observatory, developed by Russia in collaboration with Germany. The mission will be launched in March 2016 from Baikonur, by a Zenit rocket with a Fregat booster and placed in a 6-month-period halo orbit around L2. The scientific payload consists of two independent telescopes – a soft-x-ray survey instrument, eROSITA, being provided by Germany and a medium-x-ray-energy survey instrument ART-XC being developed by Russia. ART-XC will consist of seven independent, but co-aligned, telescope modules. The ART-XC flight mirror modules has been developed and fabricated at the NASA Marshall Space Flight Center (MSFC). Each mirror module will be aligned with a focal plane CdTe double-sided strip detector which will operate over the energy range of 6-30 keV, with an angular resolution of <1?, a field of view of ~34? and an expected energy resolution of about 10% at 14 keV. The current status of the ART-XC/SRG instrument will be presented.

9603-12, Session 3

Ultra high throughput four-reflection x-ray telescope for high resolution spectroscopy

Yuzuru Tawara, Ikuyuki Mitsuishi, Yasunori Babazaki, Ren Nakamichi, Ayako Bandai, Nagoya Univ. (Japan)

The first application of four-times reflection X-ray optics was used for the

DIOS mission, where very soft X-ray observation is planned. On the other hand, effective area of the telescope for higher X-ray energy (E < 10 keV) including iron K emission lines has been so far limited to about 1000 cm2 assumig several meter focal length. However, if we introduce four-reflection optics to this energy range, we can get several times large effective area for single telescope with same several meter focal length. To prove this possibility, we performed ray tracing simulation for four-relection telescope with 6 m focal length and found that effective area of 3000 cm2 at 6 keV can be obtained for single telescope. In this paper, we will discuss about other telescope performances, mechanical properties and application to fine spectroscopic mission using X-ray microcalorimeter.

9603-13, Session 3

Development of the four-stage x-ray telescope (FXT) for the DIOS mission (2)

Ikuyuki Mitsuishi, Yasunori Babazaki, Ren Nakamichi, Ayako Bandai, Yuzuru Tawara, Ikuya Sakurai, Tatsuharu Torii, Kenji Tachibana, Takefumi Onishi, Nagoya Univ. (Japan); Satoshi Sugita, Ehime Univ. (Japan); Naomichi Kikuchi, Toshiki Sato, Tokyo Metropolitan Univ. (Japan); Takayuki Hayashi, Japan Aerospace Exploration Agency (Japan); Ryo Iizuka, Yoshitomo Maeda, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan)

A Four-stage X-ray Telescope (FXT) has been developed for a small satellite mission, the Diffuse Intergalactic Oxygen Surveyor (DIOS), designed for mapping the warm-hot intergalactic medium in the nearby Universe located at z < 0.3 using redshifted highly-ionized oxygen emission lines. The FXT is a key component to achieve the scientific goal by realizing a large field of view (~50 arcmin in radius) and grasp (~100 deg2 cm2). A conventional replica foil method is employed to fabricate the FXT mirrors based on conically-approximated Wolter type I design (Tawara et al. 2014 SPIE).

We made the third FXT demonstration model and conducted both optical and X-ray measurements to investigate its performance. A thickness of the aluminum foil mirrors was changed from 0.15 mm to 0.2 mm to improve stiffness and 10 sets of 4 stage mirrors with a diameter of about 500 mm were arranged close together in a quadrant housing to reproduce a final configuration. Even though resultant angular resolution is approximately two times worse than that of the requirement, the angular resolution is reduced down to ~9 arcmin in half power diameter at 1.5 keV. We confirmed that resulting field of view is almost consistent with the expected values from simulations. In this conference, we will report on detailed results of the irradiation tests such as error budget analysis and recent status of our developments.

9603-14, Session 4

New ray-tracing capabilities for the development of silicon pore optics

Giuseppe Vacanti, Nicols Barrière, Abdelhakim Chatbi, cosine Science & Computing B.V. (Netherlands); Maximilien Collon, cosine Research B.V. (Netherlands); Ramses Günther, Alexei Yanson, Mark Vervest, cosine Science & Computing B.V. (Netherlands); Marcos Bavdaz, Eric Wille, European Space Agency (Netherlands)

The Geant4 based ray-tracer used to support the development of Silicon Pore Optics has been extended to take into account more subtle effects that affect the performance of the optics, like thermo-mechanical stresses and detailed surface metrology. Its performance has also been increased to make it possible to simulate rapidly and in detail the optics of Athena so that various possible configurations can be explored and characterized providing important feedback to the development and system teams. In this paper we report on the state of the development. Details of the geometrical objects used, and the interfaces to FEM/thermal output will be given. Preliminary performances will also be discussed.

9603-15, Session 4

Analytical computation of stray light in nested mirror modules for X-ray telescopes

Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy)

Stray light in X-ray telescopes is a well-known issue. Unlike rays focused via a double reflection by usual grazing-incidence geometries such as the Wolter-I, stray rays coming from off-axis sources are reflected only once by either parabolic or hyperbolic segment. Although not focused, stray light may represent a major source of background and ghost images especially when observing a field of faint sources in the vicinity of a more intense source just outside the field of view of the telescope. The stray-light problem is addressed by mounting a pre-collimator in front of the mirror module, in order to shade a part of the reflective surfaces that may give rise to singly-reflected rays. Studying the expected stray-light impact, and consequently designing a pre-collimator, is a typical ray-tracing problem, usually time and computation consuming, especially if we consider that rays propagate throughout a densely nested structure. This in turn requires one to pay attention to all possible obstructions, increasing the complexity of the simulation. In contrast, approaching the problems of mirror module design and stray-light calculation from an analytical viewpoint largely simplifies the problem, and also eases the task of designing an effective pre-collimator. In this work we describe an analytical formalism that can be used to compute the stray light in a nested optical module, in a fast and effective way and accounting for obstruction effects. We also show how the design of the X-ray mirror module can be optimized to return the desired field of view and at the same time minimize the stray-light effect.

9603-16, Session 4

On the statistical error of the half energy width

Giuseppe Vacanti, cosine Science & Computing B.V. (Netherlands)

The half energy width (HEW) is the all powerful performance parameter used to characterize and compare X-ray optics. Values of HEW are always reported without an error bar or confidence interval, suggesting that the statistical error associated with such estimates are neglegible. Is this true? And if it is, could one characterize the optics more quickly accepting a non-neglegible but still acceptable statistical error in the estimate of the HEW? We try to answer these questions with the use of non-parametric statistical methods. The answers obtained will be compared to the results obtained through numerical simulations.

Standard non-parametric techniques like the bootstrap can be used to answer the questions.

9603-17, Session 5

The Athena optics

Marcos Bavdaz, Eric Wille, Brian Shortt, Sebastiaan Fransen, European Space Agency (Netherlands); Maximilien Collon, cosine Research B.V. (Netherlands); Giuseppe Vacanti, Ramses Guenther, Alexei Yanson, Mark Vervest, cosine Science & Computing B.V. (Netherlands); Jeroen Haneveld, Micronit Microfluidics B.V. (Netherlands); Coen van Baren, SRON Netherlands Institute for Space Research (Netherlands); Karl-Heinz Zuknik, OHB-System AG (Germany); Finn E. Christensen, DTU Space

(Denmark); Michael Krumrey, Physikalisch-Technische Bundesanstalt (Germany); Vadim Burwitz, Max-Planck-Institut für extraterrestrische Physik (Germany); Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy); Giuseppe Valsecchi, Media Lario Technologies S.r.l. (Italy)

The Advanced Telescope for High ENergy Astrophysics (Athena) was selected in 2014 as the second large class mission (L2) of the ESA Cosmic Vision Science Programme, and system studies and technology preparation activities are on-going.

The core enabling technology for the high performance mirror is the Silicon Pore Optics (SPO), a modular X-ray optics technology, which utilises processes and equipment developed for the semiconductor industry.

The paper will provide an overview of the programmatic background, the status of SPO technology and give an outline of the development roadmap and activities undertaken and planned by ESA.

9603-18, Session 5

Silicon pore optics development for ATHENA

Maximilien Collon, cosine Research B.V. (Netherlands); Ramses Günther, Alexei Yanson, Abdelhakim Chatbi, Giuseppe Vacanti, Mark Vervest, Nicolas M. Barrière, cosine Science & Computing B.V. (Netherlands); Marco W. Beijersbergen, cosine Research B.V (Netherlands); Marcos Bavdaz, Eric Wille, European Space Agency (Netherlands); Jeroen Haneveld, Arenda Koelewijn, Micronit Microfluidics B.V. (Netherlands); Coen van Baren, SRON Netherlands Institute for Space Research (Netherlands); Peter Müller, Michael Krumrey, Physikalisch-Technische Bundesanstalt (Germany); Vadim Burwitz, Max-Planck-Institut für extraterrestrische Physik (Germany); Finn E. Christensen, DTU Space (Denmark); Giovanni Pareschi, Paolo Conconi, INAF - Osservatorio Astronomico di Brera (Italy)

The ATHENA mission, a European large (L) class X-ray observatory to be launched in 2028, will essentially consist of an X-ray lens and two focal plane instruments. The lens, based on a Wolter-I type double reflection grazing incidence angle design, will be very large (~ 3 m in diameter) to meet the science requirements of large effective area (1-2 m2 at a few keV) at a focal length of 12 m. To meet the high angular resolution (5 arc seconds) requirement the X-ray lens will also need to be very accurate.

Silicon Pore Optics (SPO) technology has been invented to enable building such a lens and thus enabling the ATHENA mission. We will report in this paper on the latest status of the development, including details of X-ray test campaigns.

9603-19, Session 5

Silicon pore optics mirror modules for inner and outer radii

Eric Wille, Marcos Bavdaz, Tim Oosterbroek, European Space Research and Technology Ctr. (Netherlands); Maximilien Collon, Marcelo D. Ackermann, cosine Research B.V. (Netherlands); Ramses Guenther, Giuseppe Vacanti, Mark Vervest, Alexei Yanson, cosine Science & Computing B.V. (Netherlands); Coen van Baren, SRON Netherlands Institute for Space Research (Netherlands); Jeroen Haneveld, Arenda Koelewijn, Anne Leenstra, Micronit Microfluidics B.V. (Netherlands); Giovanni Pareschi, Marta Civitani, Paolo Conconi, Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy); Giuseppe Valsecchi, Fabio Marioni, Media Lario Technologies S.r.l. (Italy); Mario Schweitzer, Karl-Heinz Zuknik, OHB-System AG (Germany)

Athena (Advanced Telescope for High Energy Astrophysics) is an x-ray observatory using a Silicon Pore Optics telescope and was selected as ESA's second L-class science mission for a launch in 2028. The x-ray telescope consists of several hundreds of mirror modules distributed over about 15-20 radial rings. The radius of curvature and the module sizes vary among the different radial positions of the rings resulting in different technical challenges for mirror modules for inner and outer radii.

We present first results of demonstrating Silicon Pore Optics for the extreme radial positions of the Athena telescope. For the inner most radii (0.25 m) a new mirror plate design is shown which overcomes the challenges of larger curvatures, higher stress values and bigger plates. Preliminary designs for the mounting system and its mechanical properties are discussed for mirror modules covering all other radial positions up to the most outer radius of the Athena telescope.

9603-20, Session 5

Multilayer coated SPO stack: Production and test

Sonny Massahi, Anders C. Jakobsen, David Girou, Finn E. Christensen, DTU Space (Denmark); Brian Shortt, European Space Research and Technology Ctr. (Netherlands); Maximilien Collon, cosine Research B.V. (Netherlands); Michael Krumrey, Levent Cibik, Stefanie Langner, Physikalisch-Technische Bundesanstalt (Germany)

As part of the ongoing effort to optimize the throughput of the Athena optics we have produced an SPO stack with optimized linearly graded Ir/B4C multilayer coatings. The paper describes the coating development and qualification as well as studies related to the photolithographic process, the stacking and subsequent X-ray tests at the PTB laboratory at the BESSY synchrotron radiation facility.

9603-21, Session 6

An alternative solution for ATHENA mission: preliminary design of the mirror modules and mirror assembly based on the slumped glass

Stefano Basso, Marta M. Civitani, Giovanni Pareschi, Enrico Buratti, INAF - Osservatorio Astronomico di Brera (Italy); Josef Eder, Peter Friedrich, Maria Fürmetz, Max-Planck-Institut für extraterrestrische Physik (Germany)

The Athena mission was selected for the second large-class mission, due for launch in 2028, in ESA's Cosmic Vision program. The current solution for the optics is based on the Silicon Pore Optics (SPO) technology with the goal of 2m2 effective area at 1keV (aperture about 3m diameter) with a focal length of 12m. The SPO advantages are the compactness along the axial direction and the high conductivity of the Silicon. Recent development in the fabrication of mirror shells based on the Slumped Glass Optics (SGO) makes this technology a competitive and attractive solution for the mirror modules for Athena or similar telescopes. The SGO advantages are a potential high collecting area due to the lower shadowing and the aptitude to curve the glass plates up to small radius of curvature. This study shows an alternative mirror design based on SGO technology, tailored for Athena needs. The main challenges are the optimization of the manufacturing technology with respect to the required accuracy and the thermal control of the large surface in conjunction with the low conductivity of the glass. A concept has been elaborated which considers the specific benefits of the SGO technology and provides an efficient thermal control. The output of the study is a preliminary design substantiated by analyses and technological

studies. The study proposes interfaces and predicts performances and budgets. It describes also how such a mirror system could be implemented as an alternative or as a backup solution for the SPO mirror system.

9603-22, Session 6

Slumped glass optics for x-ray telescopes: advances in the hot slumping assisted by pressure

Bianca Salmaso, Claudia Brizzolari, Stefano Basso, Marta Civitani, Mauro Ghigo, Giovanni Pareschi, Daniele Spiga, Gianpiero Tagliaferri, INAF - Osservatorio Astronomico di Brera (Italy)

Slumped Glass Optics are a viable solution to build future X-ray telescopes, such as ATHENA, with large effective area (Aeff ~ 2 m2 at 1 keV) and angular resolution better than 5 arcsec. In our laboratories we use a direct hot slumping approach assisted by pressure, in which the glass optical surface is in contact with the mould, and a pressure is applied to enforce the replication of the mould shape on the glass optical surface. Several prototypes have been already produced and tested in X-rays, showing a continuous improvement in our technology. In this paper, we present the results obtained introducing several improvements in our setup, with the use of Eagle XG glass type and Zerodur K20 material for the mould. We present a critical analysis correlating the changes in the process to the improvements in different spatial frequency ranges encompassing the profile and roughness measurements. The slumped glass foils giving the best results were integrated in a new prototype tested in X-ray at the PANTER facility. Finally, we obtained further improvements in the glass foils quality by introducing a re-polished K20 cylindrical mould, with the goal to improve the mid- to high-frequency region of the Power Spectral Density. This work presents all the relevant steps forward, in the hot slumping assisted by pressure technology, aimed at reaching angular resolutions of 5 arcsec HEW.

9603-23, Session 6

Slumped glass optics based on thin hot formed glass segments and interfacing ribs for high angular resolution x-ray astronomy: performances and development status

Marta M. Civitani, Stefano Basso, Mauro Ghigo, Bianca Salmaso, Daniele Spiga, Gianpiero Tagliaferri, Gabriele Vecchi, INAF - Osservatorio Astronomico di Brera (Italy); Gisela D. Hartner, Benedikt Menz, Vadim Burwitz, Max-Planck-Institut Röntgen Testanlage PANTER (Germany); Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

The Slumped Glass Optics technology, developed at INAF/OAB since a few years, is becoming a competitive solution for the realization of the future X-ray telescopes with a very large collecting area, as e.g. the proposed Athena, with more than 2 m2 effective area at 1 keV and with a high angular resolution (5" HEW). The developed technique is based on modular elements, named X-ray Optical Units (XOUs), made of several layers of thin foils of glass, previously formed by direct hot slumping in cylindrical configuration, and then stacked in a Wolter-I configuration, through interfacing ribs. The achievable global angular resolution of the optics relies on the surface shape accuracy of the slumped foils, on the smoothness of the mirror surfaces and on the correct integration and co-alignment of the mirror segments achieved with a dedicated Integration Machine (IMA). In this paper we provide an update of the project development, reporting on the last results achieved. In particular, we will present the results obtained with full illumination X-ray tests for the last developed prototypes.

9603-24, Session 6

Lightweight and high-resolution x-ray optics for astronomy

William W. Zhang, NASA Goddard Space Flight Ctr. (United States)

In this paper we will report our work of developing lightweight and high-resolution x-ray optics for astronomical applications. Our work has four technical elements: substrate fabrication, coating, alignment, and bonding. Each of these four elements presents unique challenges. Our strategy is to tackle all four in parallel such that each meet its own requirements. We regularly combine the four elements to make and test mirror modules consist 3 pairs of Wolter-I mirror segments. As of January 2015, all these elements are such that we can consistently produce modules that achieve full-illumination x-ray images of 8 arc-seconds half-power diameter. Our near term (next two years) objective is to be able to build modules better than 5 arc-seconds, and long term (next five years) objective to build modules better than 1 arc-second, while demonstrably preserving lightweight and low production cost of the approach.

9603-25, Session 6

Progress report on air bearing slumping of thin glass mirrors for x-ray telescopes

Mark L. Schattenburg, MIT Kavli Institute for Astrophysics and Space Research (United States); Brandon Chalifoux, Massachusetts Institute of Technology (United States); Michael D. DeTienne, Ralf Heilmann, Heng Zuo, MIT Kavli Institute for Astrophysics and Space Research (United States)

Thermal shaping (or slumping) of thin glass sheets onto high precision mandrels was used by the GSFC team to fabricate the NASA NuSTAR telescope with spectacular success. While mirrors generated by this process can have good resolution (<10 arc sec), they require very long thermal cycles. Furthermore, the required anti-stick mandrel coatings produce mid-range spatial frequency errors, slowing progress below 5 arc sec. Over the last several years we have developed a new slumping process which utilizes a pair of porous air bearing mandrels through which compressed nitrogen is forced. The glass sheet floats on a thin layer (<50 microns) of nitrogen during the thermal cycle. This results in glass with reduced mid-range spatial frequency errors and can be accomplished in much shorter thermal cycles. Recent progress has focused on improvements to a tool which slumps mirrors in a horizontal orientation. This configuration results in an unstable mirror in the bearing which must be actively controlled. Recent work has developed improved fiber sensing techniques to measure the glass location and improved Inconel bellows which control the apparatus tilt using compressed nitrogen. We report on the design and testing of this improved slumping tool.

9603-26, Session 6

Indirect glass slumping for future x-ray missions: overview, status and progress

Anita Winter, Elias Breunig, Peter Friedrich, Laura Proserpio, Max-Planck-Institut für extraterrestrische Physik (Germany); Thorsten Döhring, Hochschule Aschaffenburg (Germany)

Future X-ray telescopes aim for large effective area within the given mass limits of the launcher. A promising method is the hot shaping of thin glass sheets via a thermal slumping process. This paper presents the status and progress of the indirect glass slumping technology developed at MPE. Recent developments in our research include the successful use of the mould material Cesic under vacuum, as well as the fabrication of a high-

precision slumping mould, which meets the requirements of large, high angular resolution missions like ATHENA. The way forward to optimise the slumping process on these materials is reviewed, and the application process for a separation layer on the slumping mould to avoid sticking is described.

Furthermore we present the recent progress on the MPE integration system. The concept of force-free integration and the implementation in the laboratory are described. A real-time measurement system for detecting deformations in the mirror surface during integration has been developed and implemented. Finally the concept for an integrated mirror module segment will be presented.

In addition we have started tests and measurements on the application of a reflective coating. In collaboration with the Hochschule Aschaffenburg first tests with a sputtering facility have been performed, and the test results and analysis will be described. Additionally we present future plans for the next steps in the coating development at MPE.

9603-27, Session 7

Development of precision Wolter mirrors for future solar x-ray observations

Taro Sakao, Japan Aerospace Exploration Agency (Japan) and The Graduate Univ. for Advanced Studies (Japan); Satoshi Matsuyama, Ayumi Kime, Takumi Goto, Akihiko Nishihara, Hiroki Nakamori, Kazuto Yamauchi, Osaka Univ. (Japan); Yoshiki Kohmura, RIKEN SPring-8 Ctr. (Japan); Yoshinori Suematsu, Noriyuki Narukage, National Astronomical Observatory of Japan (Japan)

High resolution imagery of solar X-ray corona provides a crucial key to understand dynamics and heating processes of plasma particles there. However, X-ray imagery of the Sun with sub-arcsecond resolution has yet to be conducted due to severe technical difficulty in fabricating precision Wolter mirrors.

For future X-ray observations of the solar corona, we are attempting to realize precision Wolter mirrors with sub-arcsecond resolution by adopting advanced surface polish and measurement methods based on nano-technology to sector mirrors which consist of a portion of an entire circle.

Evaluation on the X-ray focusing performance at 8-10 keV of the first engineering Wolter mirror was conducted in 2013 using BL29XUL coherent X-ray beam line at SPring-8 synchrotron facility. While X-rays were focused within ~0.3" in the sagittal direction of the mirror, the focus profile was extended by ~30" in the meridional direction due mainly to residual figure ripples of amplitude ~10 nm with spatial frequency ~1 /mm.

Based on these results, we devised a systematic approach for the improvement of the precise surface polish. The final polish of the second engineering mirror was completed recently with its figure error <1 nm rms at spatial frequency around 1 /mm. Wave-optical estimate indicates that the mirror would have 0.5" FWHM spot size at 8 keV. Another X-ray evaluation at SPring-8 is scheduled in February 2015. Development activities for precision Wolter mirrors will be introduced including some measurement results.

9603-28, Session 7

Direct fabrication of full-shell x-ray optics

Mikhail V. Gubarev, NASA Marshall Space Flight Ctr. (United States); Brian Ramsey, NASA Marshall Space Flight Ctr (United States); W. Scott Smith, Jeffery Kolodziejczak, Jacqueline Roche, William Jones, William Arnold, NASA Marshall Space Flight Ctr. (United States); Carolyn Atkins, The Univ. of Alabama in Huntsville (United States)

The next generation of astrophysical missions will require fabrication technology capable of producing high angular resolution x-ray mirrors. A full-shell direct fabrication approach using modern robotic polishing machines has the potential for producing stiff and light-weight shells that can be heavily nested, to produce large collecting areas, and are easier to mount, align and assemble, giving improved angular resolution. This approach to mirror fabrication, is being pursued at MSFC. Methods for the mirror metrology, mirror-shell mounting and support during fabrication, and mirror surface figuring using a seven degrees of freedom computer-controlled polishing machine will be presented.

9603-29, Session 7

Fabrication of high resolution and lightweight monocrystalline silicon x-ray mirrors

Raul E. Riveros, Univ. of Maryland, Baltimore County (United States); Linette D. Kolos, NASA Goddard Space Flight Ctr. (United States); James R. Mazzarella, Kevin P. McKeon, SGT, Inc. (United States); William W. Zhang, NASA Goddard Space Flight Ctr. (United States)

Monocrystalline silicon as an X-ray mirror substrate material promises significant improvements over the X-ray mirror technologies used to date, since it is mechanically stiff, stress-free, highly thermally conductive, and widely commercially available. Producing highly accurate and lightweight X-ray mirrors from monocrystalline silicon requires a unique and specialized manufacturing process capable of producing mirrors quickly and cost effectively. The identification, development, and testing of this process is the focus of the work described in this proceeding. Monocrystalline silicon blocks were obtained, and a variety of processes (wire electro-discharge machining, etching, polishing) were applied to generate an accurate and stress-free cylindrical or Wolter-I mirror surface. The mirror surface is then sliced off at a thickness of 0.5 mm and further processed to yield an X-ray mirror segment with < 3" slope errors. Furthermore, our experiments suggest that this mirror production process requires only four days to produce a mirror segment and is easily integrated into a cost-reducing parallel processing scheme. Presently, there is strong evidence that the mirror production process described in this paper will meet the stringent requirements of future X-ray missions.

9603-30, Session 7

Development of light weight replicated x-ray optics

Suzanne E. Romaine, Ricardo Bruni, Harvard-Smithsonian Ctr. for Astrophysics (United States); Brian Choi, Christopher Jensen, ReliaCoat Technologies, LLC (United States); Brian D. Ramsey, National Space Science and Technology Ctr. (United States); Sanjay Sampath, ReliaCoat Technologies, LLC (United States)

NASA'S future X-ray astronomy missions will require X-ray optics that have large effective area while remaining lightweight, and cost effective. Some X-ray missions, such as XMM-Newton , and the upcoming Spectrum-Röntgen-Gamma mission use an electroformed nickel replication (ENR) process to fabricate the nested grazing incidence X-ray telescope mirror shells for an array of moderate resolution, moderate effective area telescopes. We are developing a process to fabricate metal-ceramic replicated optics which will be lighter weight than current nickel replicated technology. Our technology development takes full advantage of the replication technique by fabricating large diameter mirrors with thin cross sections allowing maximum nesting and increase in collecting area. This will lead to future cost effective missions with large effective area and lightweight optics with good angular resolution.

Recent results on fabrication and testing of these optics are presented.

9603-31, Session 8

Alignment, bonding, and testing of lightweight x-ray mirrors

Kai-Wing Chan, Michael P. Biskach, Joseph Bonafede, Linette D. Kolos, James R. Mazzarella, NASA Goddard Space Flight Ctr. (United States); Ryan S. McClelland, Kevin P. McKeon, SGT, Inc. (United States); Jason Niemeyer, Raul E. Riveros, Timo T. Saha, NASA Goddard Space Flight Ctr. (United States); Mark J. Schofield, SGT, Inc. (United States); Marton V. Sharpe, William W. Zhang, NASA Goddard Space Flight Ctr. (United States)

Lightweight, high-resolution, high throughput optics for x-ray astronomy requires fabrication and integration of thin mirrors segments with arc-second precision. In this paper, we present recent advance on alignment, bonding and testing lightweight glass and silicon mirrors developed at NASA/Goddard Space Flight Center. We address techniques of alignment and bonding of such thin mirrors that produce segmented mirror modules with angular resolution better than 10 arc-seconds. Critical opto-mechanical and thermal issues related to integrating such high resolution mirrors are addressed. We show that the bonded-in mirrors are stable and survive thermal excursion that modules may encounter in a flight mission.

9603-32, Session 8

Cold shaping of thin glass foils: a fast and cost-effective solution for making light-weight astronomical x-ray optics

Marta M. Civitani, Stefano Basso, Oberto Citterio, Mauro Ghigo, Bianca Salmaso, Gianpiero Tagliaferri, Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

Recent advancements in thin glass materials allowed the development and the mass production of very thin glass foils, like e.g. the Willow glass (thickness of 0.1-0.2 mm) produced by Corning or AF32 produced by by Schott (thickness of 0.055 mm). The thickness, strength and flexibility of these glass foils allow bending them up to very small radius of curvature without breaks. This feature, together with the very low micro-roughness, makes this kind of materials ideal candidates for pursuing a cold replication approach for cost-effective and fast making of grazing incidence astronomical optics. Starting from the very thin flat glass sheets, the process under development foresees to bond them onto the supporting structure while they are wrapped around reference mandrels. The assembly concept, based on the use of Wolter-I counter-form moulds, is also based on the use of reinforcing ribs that connect pairs of consecutive foils in the final assembly. The ribs do not only play the role of mechanical connectors, they keep the shape and increase the structural stiffness. Indeed, the ribs constrain the foil profile to the correct shape during the bonding, damping the low-frequency residuals with respect to the Wolter I configuration. This approach is particularly interesting because of their low weight and cost. They could e.g be used for the production of high throughput optics as those needed for the Chines XTP mission, in which the requirements on the angular resolution are not too tight. In fact, a Half Energy Width in the range of 20-60 arcsec is compatible with the expected residual error due to the spring back of the glass sheets. In this paper we provide an overview of the project, the expected performances and presents the first preliminary results.

9603-33, Session 8

JIM: a joint integrated module of glass x-ray optics for astronomical telescopes

Laura Proserpio, Max-Planck-Institut für extraterrestrische Physik (Germany); Stefano Basso, INAF - Osservatorio Astronomico di Brera (Italy); Elias Breunig, Max-Planck-Institut für extraterrestrische Physik (Germany); Enrico Buratti, INAF - Osservatorio Astronomico di Brera (Italy); Vadim Burwitz, Max-Planck-Institut für extraterrestrische Physik (Germany); Marta Civitani, INAF - Osservatorio Astronomico di Brera (Italy); Josef Eder, Peter Friedrich, Gisela D. Hartner, Benedikt Menz, Christian Rohé, Anita Winter, Max-Planck-Institut für extraterrestrische Physik (Germany)

Since several years, the Max-Planck-Institute for extraterrestrial Physics in Germany (MPE) and the Astronomical Observatory of Brera in Italy (INAF-OAB) have been studying the slumping technology for the manufacturing of segmented glass X-ray optics for astronomy. Despite some differences in their specific approaches, the synergy of the two institutes has always been fruitful, focusing on the common goal of developing a technology able to meet the challenging requirements for future X-ray telescopes: i.e. large collecting areas, low mass and good angular resolution. In the last year, this synergy has resulted in an active collaboration for the production of a Joint Integrated Module (JIM) that puts together the expertise of the two research groups. In particular, the indirect slumping approach of MPE has been employed for the manufacturing of X-ray mirror segments, which has then been integrated into an X-ray Optical Unit following the approach developed at INAF-OAB; at this purpose, the appositely designed and developed Integration Machine (IMA) has been employed. The module has finally been tested in X-ray at the MPE PANTER facility, in Neuried. The several steps and the results of this joint activity are reviewed and discussed in this paper.

9603-34, Session 8

Liquid metal actuators: correctable mounting and assembly of thin-shell x-ray telescope mirrors

Alexander R. Bruccoleri, Martin L. Klingensmith, Brandon D. Chalifoux, Ralf K. Heilmann, Mark L. Schattenburg, Massachusetts Institute of Technology (United States)

An ideal bonding agent for thin-shell x-ray mirrors could be quickly applied to joints and set with deterministic and stable properties. Unfortunately, mirror assembly methods have typically utilized various epoxy formulations which are messy, slow to apply and cure, and far from deterministic or stable. Problems include shrinkage, creep and high thermal and humidity sensitivity. Once the bond is set errors are frozen in and can't be corrected. We are developing a new method for bonding thin-foil mirrors that has the potential to solve these problems. Our process to bond mirrors to housing reference points is achieved via small beads of a low-melting-point bonding agent (such as solder or thermoset). The mirror is bonded to small contact surface points under real-time metrology. If the position of the mirror needs to be adjusted after bonding, a small force is applied normal to the contact surface and a pulsed fiber laser is used to melt an ultrathin layer of the solder for a very short time. The joint is then compressed or stretched while molten before refreezing in a new position, enabling repeatable and stable mirror position adjustments along the direction of the force in nm-level steps with minimal heat input. We present results from our prototype apparatus demonstrating proof of principle. The initial experiment includes developing a technique to bond D263 glass to invar, designing and building a one-dimensional stage to precisely apply force, and applying an infrared laser to heat the joint while measuring position and force.

9603-35, Session 9

High-efficiency blazed transmission gratings for high-resolution soft x-ray spectroscopy

Ralf K. Heilmann, MIT Kavli Institute for Astrophysics and Space Research (United States); Alexander R. Bruccoleri,

Izentis, LLC (United States); Mark L. Schattenburg, MIT Kavli Institute for Astrophysics and Space Research (United States)

High-resolution spectroscopy of astrophysical sources is the key to gaining a quantitative understanding of the history, dynamics, and current conditions of the cosmos. A large-area (> 1,000 cm2), high resolving power (R =lambda/Dlambda > 3,000) soft x-ray grating spectrometer that covers the lines of C, N, O, Ne and Fe ions is the ideal tool to address a number of high-priority sciences questions from the 2010 Decadal Survey, such as the connection between super-massive black holes and large-scale structure via cosmic feedback, the evolution of large-scale structure, the behavior of matter at high densities, and the conditions close to black holes. However, no grating missions or instruments are currently approved. To improve the chances for future soft x-ray grating spectroscopy missions, grating technology has to progress and advance to higher TRLs. We have developed Critical-Angle Transmission (CAT) gratings that combine the advantages of blazed reflection gratings (high efficiency, use of higher diffraction orders) with those of conventional transmission gratings (low mass, relaxed alignment tolerances and temperature requirements, transparent at higher energies). A CAT grating-based spectrometer can provide performance 1-2 orders of magnitude better than current grating instruments on Chandra and Newton-XMM with minimal resource requirements. We have fabricated large-area free-standing CAT gratings with minimal integrated support structures from silicon-on-insulator wafers using advanced lithography and a combination of deep reactive-ion and wet etching, and will present our latest x-ray test results showing record high diffraction efficiencies in blazed orders.

9603-36, Session 9

X-ray and optical alignment approaches to off-plane reflection gratings

Ryan Allured, Harvard-Smithsonian Ctr. for Astrophysics (United States); Benjamin D. Donovan, The Univ. of Iowa (United States); Vadim Burwitz, Max-Planck-Institut für Astrophysik (Germany); Peter N. Cheimets, Harvard-Smithsonian Ctr. for Astrophysics (United States); Casey T. DeRoo, The Univ. of Iowa (United States); Gisela Hartner, Max-Planck-Institut für Astrophysik (Germany); Hannah R. Marlowe, The Univ. of Iowa (United States); Randall L. McEntaffer, The Univ. of Iowa (United States); Edward Hertz, Harvard-Smithsonian Ctr. for Astrophysics (United States); Benedikt Menz, Max-Planck-Institut für Astrophysik (Germany); Randall K. Smith, Harvard-Smithsonian Ctr. for Astrophysics (United States); James H. Tutt, The Univ. of Iowa (United States)

Off-plane reflection gratings offer the potential for high-resolution, high-throughput x-ray spectroscopy on future missions. Most mission concepts, such as Arcus or SMART-X, involve gratings placed in the path of a converging x-ray beam from an x-ray telescope. In the off-plane reflection grating case, these gratings must be co-aligned such that their diffracted spectra overlap at the focal plane. Misalignments degrade spectral resolution and effective area. In-situ x-ray alignment of a pair of off-plane reflection gratings in the path of an SPO module has recently been performed at the PANTER beamline in Germany. The diffracted spectra achieved spectral overlap to within the quality of the SPO point spread function. For a flight-like mission concept, however, in-situ x-ray alignment may not be feasible. In that event, optical methods must be developed to achieve spectral alignment. We have designed and fabricated a flight-like grating module for integration with an SPO module. Metrology techniques have been developed and used to populate the grating module and align it to the SPO. Finally, the combined SPO and grating modules have been taken to PANTER for x-ray performance testing.

9603-37, Session 9

Diffraction efficiency measurements of radially-profiled off-plane gratings

Drew M. Miles, Hannah R. Marlowe, Jake A. McCoy, Randall L. McEntaffer, Thomas J. Peterson, Ted B. Schultz, James H. Tutt, The Univ. of Iowa (United States); Thomas D. Rogers, Univ. of Colorado at Boulder (United States); Christian Laubis, Frank Scholze, Physikalisch-Technische Bundesanstalt (Germany)

Future X-ray missions will require gratings with high throughput and high spectral resolution. Blazed off-plane reflection gratings are capable of meeting these demands. A blazed grating profile optimizes grating efficiency, providing higher throughput to one side of zero-order on the arc of diffraction. This paper presents efficiency measurements made in the 0.3 – 1.5 keV energy band at the Physikalisch-Technische Bundesanstalt (PTB) BESSY II facility for three radially-profiled, holographically-ruled gratings, two of which are blazed. Each blazed grating was tested in both the Littrow configuration and anti-Littrow configuration in order to test the alignment sensitivity of these gratings with regard to throughput. In addition, efficiency measurements are provided on all three gratings with incoming light parallel to the groove direction. This paper will outline the procedure of the grating experiment performed at BESSY II and discuss the resulting efficiency measurements across various energies. Experimental results were generally consistent with theory and demonstrate that the blaze does increase throughput to one side of zero-order. However, the total efficiency of the non-blazed, sinusoidal grating is greater than that of the blazed gratings, which suggests that the method of manufacturing these blazed profiles fails to produce facets with the desired level of precision. Finally, efficiency models for the two grating arrays that will fly on board the suborbital rocket payload, Off-plane Grating Rocket for Extended Source Spectroscopy (OGRESS), will be presented along with an analysis of the grating performance from the mission.

9603-38, Session 10

Polarization sensitivity of blazed, off-plane reflection gratings in the soft x-ray regime

Hannah R. Marlowe, James H. Tutt, Casey T. DeRoo, Drew M. Miles, Randal L. McEntaffer, The Univ. of Iowa (United States); Frank Scholze, Christian Laubis, Physikalisch-Technische Bundesanstalt (Germany)

X-ray diffraction gratings in the off-plane, or conical mount, are able to achieve higher spectral resolution and efficiency than their in-plane counterparts. They also offer favorable packing geometries and are able to reach very large absolute efficiencies at high orders. In addition to these benefits, efficiency calculations show that unlike in the in-plane configuration, gratings in the off-plane mount have noticeable efficiency variations between TM and TE waves which can be exploited to extract polarization information of incident radiation. Therefore, these gratings have the potential to enable and support next generation X-ray polarimetry missions. We present expectations and results of the polarization sensitivity of blazed, off-plane reflection gratings in the 30-1800 eV regime taken at the BESSY II synchrotron using the PTB beamline. In addition, specific instrument applications in the context of current mission concepts will be discussed.

9603-39, Session 10

New laterally graded multilayer mirrors for soft x-ray polarimetry

Herman L. Marshall, Norbert S. Schulz, Massachusetts Institute of Technology (United States); David L. Windt,

Reflective X-Ray Optics LLC (United States); Eric M. Gullikson, Lawrence Berkeley National Lab. (United States); Eric Blake, Univ. of Massachusetts Lowell (United States); Dan Getty, Massachusetts Institute of Technology (United States); Zane McInturff, Univ. of Wisconsin-Madison (United States); John A. Clarke, Massachusetts Institute of Technology (United States)

We present continued development of laterally graded multilayer-coated mirrors (LGMMs) for a telescope design capable of measuring linear X-ray polarization over a broad X-ray band. The multilayer-coated mirrors are used as Bragg reflectors at the Brewster angle. By matching to the dispersion of a spectrometer, one may take advantage of high multilayer reflectivities and achieve polarization modulation factors over 50% over the entire 0.2-0.8 keV band. Previously, we demonstrated that the polarimetry beam-line provides 100% polarized X-rays at 0.525 keV (Marshall et al. 2013). Recently, we augmented the system using a LGMM to create a source of polarized X-rays at energies from 180 eV to 525 eV. Here, we will present results from continued development that includes LGMMs of new material combinations (C/CrCo and La/B4C) with high efficiencies in different soft X-ray bands. We have also sponsored the development of new gratings and anticipate showing results from testing these new gratings.

Support for this work was provided by the National Aeronautics and Space Administration through grant NNX12AH12G and by Research Investment Grants from the MIT Kavli Institute.

9603-40, Session 10

High efficiency carbon-based multilayers for LAMP at 250 eV

Mingwu Wen, Qiushi Huang, Tongji Univ. (China); Rui She, Tsinghua Univ. (China); Li Jiang, Zhong Zhang, Zhanshan Wang, Tongji Univ. (China); Hua Feng, Tsinghua Univ. (China); Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy)

X-ray reflection near the Brewster's angle by multilayer mirrors can be used to detect the polarization from X-ray sources. The photon spectra from some isolated neutron stars and AGN/blazars etc. show that their emission is peaked at low energies near 250eV, which is just below carbon K-absorption edge. The Lightweight Asymmetry and Magnetism Probe (LAMP) is proposed as a micro-satellite mission dedicated for astronomical X-ray polarimetry working at 250 eV and is currently under early phase study. Different carbon-based multilayers including Co/C, Cr/C, and Co8Cr2/C are selected and designed at the energy near 250eV with a grazing incident angle of 45°. The carbon layer thickness ratio is optimized to get the highest integral reflectivity which means more effective signals in the astrophysics observation. The multilayer coatings are manufactured by direct current magnetron sputtering and characterized using Grazing incidence X-ray reflectometry (GIXR) at 8keV. Different base vacuum pressures were investigated to study the influence of e.g. oxygen and nitrogen in the vacuum. Reactive sputtering with 2%, 4%, 6% and 8% nitrogen, respectively, were also used to improve the Co/C multilayer interfaces. The fittings to GIXR results and atomic force microscopy (AFM) measurements show that both the interlayer and surface roughness can be reduced using reactive sputtering.

9603-41, Session 10

Testing multilayer-coated nickel mirrors for the LAMP x-ray polarimetric telescope

Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy); Zhanshan Wang, Tongji Univ. (China); Robert Banham, Media Lario Technologies S.r.l. (Italy); Enrico Costa, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Hua Feng, Tsinghua Univ. (China); Angelo Giglia, Elettra-Sincrotrone Trieste S.C.p.A. (Italy); Qiushi Huang, Tongji Univ. (China); Fabio Muleri, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Giovanni Pareschi, Bianca Salmaso, INAF - Osservatorio Astronomico di Brera (Italy); Rui She, Tsinghua Univ. (China); Paolo Soffitta, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Gianpiero Tagliaferri, INAF - Osservatorio Astronomico di Brera (Italy); Kashmira Tayabaly, Politecnico di Milano (Italy) and INAF - Osservatorio Astronomico di Brera (Italy); Giuseppe Valsecchi, Media Lario Technologies S.r.l. (Italy); Mingwu Wen, Tongji Univ. (China)

The LAMP (Lightweight Asymmetry and Magnetism Probe) polarimetric X-ray telescope is a mission concept to analyze the polarization of X-ray sources in the Universe at 250 eV via focusing mirrors near the Brewster angle, i.e., at angles of 40 to 50 deg. Hence it will require the adoption of multilayer coatings with a few nanometers d-spacing in order to enhance the reflectivity. The Nickel electroforming technology has already been successfully used to fabricate the high angular resolution imaging mirrors of the X-ray telescopes SAX, XMM-Newton, and Swift/XRT. We are investigating this consolidated technology as a possible technique to manufacture focusing mirrors for LAMP. Although the very good reflectivity performances of this kind of mirrors were fully demonstrated in grazing incidence, the reflectivity and scattering properties have not yet been tested directly at the unusual large 45 deg angle. In this paper we present the results of the X-ray reflectivity campaign performed at the BEAR beamline at ELETTRA Sincrotrone Trieste on 12 electroformed Nickel samples with multilayer coatings of various composition (Cr/C, Co/C, Fe/C), using polarized X-rays at 250 eV. We deal with an analysis of the reflectivity curves in order to derive the polarizing properties, the multilayer structure, and the roughness/diffuseness characteristics. We also perform a comparison of the results with the expectations obtained from the roughness measured by Atomic Force Microscopy.

9603-42, Session 11

Advancements in hard x-ray multilayers for x-ray astronomy

David L. Windt, Reflective X-Ray Optics LLC (United States)

The development in recent years of nanometer-scale X-ray multilayer coatings that provide high reflectance over a broad spectral band at energies above 10 keV, in combination with the simultaneous development of thin-shell cylindrical mirror substrates, has enabled the construction of efficient, light-weight, hard X-ray astronomical telescopes, embodied most notably in the NuSTAR instrument launched in 2012. This new hard X-ray optics capability has in turn led to ground-breaking observations of a variety of Galactic and extra-Galactic objects.

Future X-ray astronomy missions currently being formulated that will use multilayer X-ray optics technology will require performance that exceeds what can be achieved at present. In particular, there is a need for new X-ray multilayer coatings that have higher reflectance, and that operate at even higher energies than the W- and Pt-based multilayer coatings used for NuSTAR. Furthermore, as the angular resolution of the thin-shell mirror substrates approaches one arc-second and beyond, achieving near-zero multilayer film stress will become an increasingly important requirement, in order to avoid stress-driven substrate deformations that would otherwise degrade angular resolution.

In this presentation, recent investigations into a variety of new multilayer designs, materials combinations, film deposition techniques, and film characterization techniques will be described. The overarching goal of these investigations is the development of high-performance, low-stress, hard X-ray multilayer coatings for use in future X-ray astronomy missions.

9603-43, Session 11

Development of Ni-based multilayers for future focusing soft gamma ray telescopes

David Girou, Erlend Sleire, Sonny Massahi, Finn E. Christensen, Anders C. Jakobsen, DTU Space (Denmark)

The hard X-ray focusing telescopes on the NuSTAR mission and to be flown on the ASTRO-H mission uses depth graded multilayer coatings to extend the energy bandwidth to the hard X-ray range. For both missions the upper energy range is limited to 79.4 keV by the Pt-K absorption edge of the constituent heavy material. One possible solution for extending the energy bandwidth into the soft gamma ray range of several hundred keV is to use Ni as the heavy element in the multilayer as this material does not have absorption edges in hard X-ray/soft gamma ray range. This paper reports on our current status of developing these coatings in the DC magnetron sputtering facility at DTU-space including the combined methods of collimation, reactive sputtering using Nitrogen and heating of the substrates.

9603-44, Session 11

A soft gamma-ray concentrator using thin-film multilayer structures

Peter F. Bloser, Paul Aliotta, Olof Echt, James Krzanowski, Jason S. Legere, Mark L. McConnell, Farzane Shirazi, John Tsavalas, Emily Wong, The Univ. of New Hampshire (United States)

We have begun to investigate the use of thin-film, multilayer structures to form optics capable of concentrating soft gamma rays with energies greater than 100 keV, beyond the reach of current grazing-incidence hard X-ray mirrors. Alternating layers of low- and high-density materials (e.g., polymers and metals) will channel soft gamma-ray photons via total external reflection. A suitable arrangement of bent structures will then concentrate the incident radiation to a point. Gamma-ray optics made in this way offer the potential for soft gamma-ray telescopes with focal lengths of less than 10 m, removing the need for formation flying spacecraft and opening the field up to balloon-borne instruments. Building on initial investigations at Los Alamos National Laboratory, we are investigating whether it is possible to grow such flexible multi-layer structures with the required thicknesses and smoothness using magnetron sputter and pulsed laser deposition techniques. We will present the initial results of tests aimed at fabricating such structures using both spin coating and pulsed laser deposition, and demonstrating gamma-ray channeling of 122 keV photons in the laboratory. If successful, this technology offers the potential for transformational increases in sensitivity while dramatically improving the system-level performance of future high-energy astronomy missions through reduced mass and complexity.

9603-45, Session 12

Progress in differential deposition for improving the figures of full-shell astronomical grazing incidence x-ray optics

Kiranmayee Kilaru, NASA Marshall Space Flight Ctr. (United States); Carolyn Atkins, The Univ. of Alabama in Huntsville (United States); Brian D. Ramsey, Mikhail V. Gubarev, David M. Broadway, NASA Marshall Space Flight Ctr. (United States)

One of the developments at MSFC that is underway to meet the demand of high-resolution X-ray optics for the support of future X-ray astronomy missions is the 'differential deposition' technique. This process corrects the axial figure profile of optics by selectively depositing material onto the mirror's surface. The process relies on accurate metrology achieved using a long trace profiler whose slope resolution is better than 1μrad. From these metrology data an error map is generated that shows the profile of material to be deposited to correct the optic's figure. A computer-controlled deposition system then applies this corrective coating.

Simulations show that substantial improvements in angular resolution are possible. To date, custom coating systems have been developed and corrections of full-shell optics are underway. This presentation gives an overview of the program and results obtained to date.

9603-46, Session 12

Differential deposition correction of segmented glass x-ray optics

Carolyn Atkins, The Univ. of Alabama in Huntsville (United States); Kiranmayee Kilaru, Brian D. Ramsey, David M. Broadway, Jessica A. Gaskin, Mikhail V. Gubarev, Stephen L. O'Dell, NASA Marshall Space Flight Ctr. (United States); William W. Zhang, NASA Goddard Space Flight Ctr. (United States)

One of the challenges faced within the astronomical X-ray community is how to produce lightweight high angular resolution optics for a future X-ray mission capable of probing the early X-ray universe. To this end, the differential deposition project at NASA's MSFC is looking to improve current X-ray optic technology by applying a corrective coatings with a goal of achieving arc-second-level resolution. Recently at MSFC we have commissioned two new vacuum deposition chambers explicitly for this research. One chamber corrects the full shell NiCo mirrors fabricated at the MSFC and the other corrects the segmented glass optics fabricated by GSFC.

This paper will focus on the correction of the segmented glass optics and the paper will highlight: the design of the chamber and internal mechanics; the algorithm used to perform the correction; metrology of the glass segments; and the improvement in resolution post correction that has been achieved to date.

9603-47, Session 12

Two-dimensional differential deposition for figure correction of thin-shell mirror substrates for x-ray astronomy

David L. Windt, Reflective X-Ray Optics LLC (United States); Raymond Conley Jr., Argonne National Lab. (United States)

Future X-ray astronomy missions will likely use light-weight X-ray telescopes constructed from thin-shell mirror segments. To realize angular resolution of 1" or better, figure errors in the mirror substrates must be sufficiently controlled over all relevant spatial frequencies. In particular, axial mid-frequency surface-height errors (i.e., with lateral scales in the range 1 – 10 mm) must be controlled to better than ~0.5 nm in order to achieve 1" resolution.

We describe a new technique for correction of mid-frequency, surface-height errors in thin-shell mirror segments. The technique is based on the differential deposition concept, wherein material is added to the substrate surface (e.g., using magnetron sputtering) so as to fill in the 'valleys' and thus reduce the magnitude of surface-height errors. Other differential deposition techniques currently being pursued for figure correction modulate the velocity of the substrate as it moves past a fixed-width aperture placed over the sputter source, providing one-dimensional film thickness control. In contrast, our new approach provides two-dimensional control of film thickness so that surface-height errors along adjacent strips spanning the entire substrate surface can be corrected simultaneously. We use a constant substrate velocity in conjunction with an array of ~5-mm-wide dynamically-actuated apertures: as the substrate moves past the

sputter source, each of the apertures is modulated individually, in real-time, in accord with a pre-measured surface-height map. Preliminary results will be presented on the development of the necessary film deposition and surface metrology techniques, including the crucial development of dynamically-actuated apertures suitable for use with magnetron sputtering.

9603-49, Session 13

Compensating for piezo-electric materials processing stresses in adjustable x-ray optics

Katie Ames, Ricardo Bruni, Paul B. Reid, Suzanne E. Romaine, Harvard-Smithsonian Ctr. for Astrophysics (United States)

Adjustable X-ray optics represent an enabling technology for simultaneously achieving large effective area and high angular resolution. The adjustable optics employ a bimorph mirror composed of a thin (1.5 um) film of piezoelectric material deposited on the back of a 0.4 mm thick conical mirror segment.

The application of localized electric fields in the piezoelectric material, normal to the mirror surface, result in localized deformations in mirror shape. Thus, mirror fabrication and mounting induced figure errors can be corrected, without the need for a massive reaction structure. A problem encountered with this approach is that film stresses in the piezoelectric layer, resulting from deposition, crystallization, and differences in coefficient of thermal expansion, can distort the mirror. The large relative thickness of the piezoelectric material means that even 100MPa stresses can result in significant distortions.

We have examined compensating for the piezoelectric processing related distortions by the deposition of controlled stress iridium films on the front surface of the mirror. We describe our experiments to balance the stress resulting from the piezoelectric layer. We also evaluated the repeatability of this deposition process, and the robustness of the iridium coating.

9603-50, Session 13

Stress manipulated coating: a new surface correction method for light weight x-ray optics

Youwei Yao, Xiaoli Wang, Jian Cao, Michael E. Graham, Semyon Vaynman, Shannon E. Grogans, Yifang Cao, Melville P. Ulmer, Northwestern Univ. (United States)

We present a stress manipulated coating method for light weight X-ray optics to improve the figure quality. The principle of this idea is to produce local stress in coating on the non-reflecting surface of the mirror to correct the surface profile. In order to demonstrate a proof of concept, a standard magnetron sputtering system was modified. First, a mask with a slit has been fixed under the sputtering source to restrict the flow of coating material. Second, the sample holder was put on a translation stage which was mounted below the mask. Then, an adjustable bias circuit was attached to the sample holder. The result was a set up that allowed us to vary locally the coating stress. To demonstrate repeatability of stress with a set bias, 5 test glass pieces (20mm by 5mm by 0.2mm) were coated with a 100nm Cr layer under a constant bias of -62.5V. The curvatures of the samples before and after coating were measured by a Dektak profilometer. The results suggest that the method could improve the surface profile by factor of over 160 down to slope errors of below 1 arc second. In addition, a sinusoidal waviness over the length scale of 10mm was produced on a test glass piece to demonstrate the feasibility of manipulating the surface figure via a changing stress. The measured profile was consistent with our FEA simulation. These results suggest the method has a promising future for reducing the cost of high quality (arc second) X-ray optics.

9603-51, Session 13

Ion implantation for figure correction of segmented x-ray telescope mirror substrates

Brandon D. Chalifoux, Graham Wright, Ralf K. Heilmann, Mark L. Schattenburg, Massachusetts Institute of Technology (United States)

Figure correction of x-ray telescope mirrors may be critical for future missions that require high resolution and large collecting areas. Ion implantation offers a method of correcting figure errors by imparting sub-surface strain in a controllable magnitude and location. In this paper, we demonstrate that sufficient strain can be applied to achieve significant figure correction in D-263 glass, Eagle XG glass, and silicon. Figure correction with equibiaxial strain applied to the surface, regardless of how the strain is applied, requires large strain at high spatial frequency to provide substantial figure correction. In contrast, if a general strain can be applied to the surface, then nearly exact correction can be made using small strains at low spatial frequencies. We show that in some materials, such as D-263 glass, substantial anisotropic strain can be generated. This may provide substantial improvement in the ability to correct figure errors. We will also report on progress to build a vacuum chamber capable of imposing non-uniform ion dose distributions on a mirror substrate.

9603-52, Session 14

Development of adjustable x-ray optics with 0.5 arcsec resolution: a status update

Paul B. Reid, Ryan Allured, Sagi Ben-Ami, Vincenzo Cotroneo, Harvard-Smithsonian Ctr. for Astrophysics (United States); Edward Hertz, Smithsonian Astrophysical Observatory (United States); Raegan L. Johnson-Wilke, Sandia National Labs. (United States); Vanessa Marquez, Smithsonian Astrophysical Observatory (United States); Stuart McMuldroch, Daniel A. Schwartz, Harvey D. Tananbaum, Harvard-Smithsonian Ctr. for Astrophysics (United States); Susan Trolier-McKinstry, The Pennsylvania State Univ. (United States); Alexey A. Vikhlinin, Harvard-Smithsonian Ctr. for Astrophysics (United States); Margeaux L. Wallace, The Pennsylvania State Univ. (United States); Rudeger H. T. Wilke, Sandia National Labs. (United States)

Adjustable grazing incidence X-ray optics represent a candidate technology for the development of the successor to the Chandra X-ray Observatory. The adjustable optics, produced by depositing a thin film of piezoelectric material on the back surface of a Wolter mirror segment, represents a way in which mirror figure errors resulting from fabrication and mounting can be corrected once on the ground. After launch, it may also be feasible to make on-orbit corrections for figure changes due to thermal effects. This powerful technology does not require massive reaction structures, and will make possible the simultaneous achievement of very large effective area and sub-arcsecond X-ray imaging.

We describe recent progress in our continuing development of adjustable X-ray optics. We discuss improvements in piezoelectric lifetime and yield, development of a mirror segment alignment approach consistent with sub-arcsecond imaging, demonstration of deterministic figure correction on flat test mirrors, and progress towards X-ray testing of a mounted, aligned, and corrected pair of mirrors.

9603-53, Session 14

Improved control and characterization of adjustable x-ray optics

Ryan Allured, Sagi Ben-Ami, Vincenzo Cotroneo, Vanessa Marquez, Stuart McMuldroch, Paul B. Reid, Daniel A. Schwartz, Harvard-Smithsonian Ctr. for Astrophysics (United States); Susan Trolier-McKinstry, The Pennsylvania State Univ. (United States); Alexey A. Vikhlinin, Harvard-Smithsonian Ctr. for Astrophysics (United States); Margeaux L. Wallace, The Pennsylvania State Univ. (United States)

We report on significant improvements on the metrology systems and control systems for piezoelectrically adjustable X-ray optics. In the past, an optical profilometer and Shack-Hartmann wavefront sensor have been used to measure several influence functions for a flat adjustable mirror. We have since performed a full calibration of a flat mirror and used a multi-channel DAC to induce pre-determined figure changes to the mirror, representing our first attempt at figure control of a full mirror. Furthermore, we have adapted our metrology systems to a cylindrical geometry, allowing characterization of Wolter-type mirrors. We review measurements of figure, roughness, and influence functions of a cylindrical mirror and finally discuss implications for future work.

9603-54, Session 14

Manufacturing and testing a thin glass mirror shell with piezoelectric active control

Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy); Marco Barbera, Univ. degli Studi di Palermo (Italy); Stefano Basso, Marta Civitani, INAF - Osservatorio Astronomico di Brera (Italy); Alfonso Collura, Ugo Lo Cicero, INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Giuseppe Lullo, Univ. degli Studi di Palermo (Italy); Carlo Pelliciari, Marco Riva, Bianca Salmaso, INAF - Osservatorio Astronomico di Brera (Italy); Luisa Sciortino, Univ. degli Studi di Palermo (Italy)

Optics for future X-ray telescopes will be characterized by very large aperture and focal length, and will be made of lightweight materials like glass or Silicon in order to keep the total mass within acceptable limits. Optical modules based on thin slumped glass foils are being developed at various institutes, aiming at improving the angular resolution to a few arcsec HEW. Thin mirrors are prone to deform, so they require a careful integration to avoid deformations and even correct forming errors. On the other hand, this offers the opportunity to actively correct the residual deformation: a viable possibility to improve the mirror figure is the application of piezoelectric actuators onto the non-optical side of the mirrors, and several groups are already at work on this approach. The concept we are developing consists of actively integrating thin glass foils with piezoelectric patches, fed by voltages driven by the feedback provided by X-rays. The actuators are commercial components, while the tension signals are carried by a printed circuit obtained by photolithography, and the driving electronic is a multi-channel low power consumption voltage supply developed in-house. Finally, the shape detection and the consequent voltage signal to be provided to the piezoelectric array are determined in X-rays, in intra-focal setup at the XACT facility at INAF/OAPA. In this work, we describe the manufacturing steps to obtain a first active mirror prototype and the first test performed in X-rays.

9603-55, Session 14

Investigation of magnetically smart films applied to correct the surface profile of light weight x-ray optics in two directions

Xiaoli Wang, Youwei Yao, Jian Cao, Michael E. Graham, Semyon Vaynman, Tianchen Liu, Melville P. Ulmer, Northwestern Univ. (United States)

Our goal is to improve initially fabricated X-ray optics figures by applying a magnetic field to drive a magnetic smart material (MSM) coating on the backside of the mirror. The consequent deformation of the surface should be three-dimensional. Here we will report on the results of working with a glass sample of 50x50x0.2 mm that has been coated with MSMs. The coated glass can be deformed in 3 dimensions and its surface profile will be measured under our Zygo NewView white light interferometer (WLI). The driving magnetic field will be produced via a pseudo-magnetic write head made up of two permanent magnet posts. The magnet posts can be moved around the glass sample with a 3-d computer controlled translation stage. The system allows four degrees of freedom of motion, i.e., up and down, side to side, back and forth, and rotation of the posts (3 mm diameter) about the vertical axis to allow us to change the orientation of the magnetic field in the (horizontal) plane of the sample. Key features of the design are that the positions can be controlled and recorded by a computer, and that the device is compact enough so the surface deflections of the shaped piece can be measured in situ with WLI. We will establish a FEA model to predict deformations and compare with the observed results in order to demonstrate that magnetically controlled MSMs can be used to improve X-ray optics figures.

9603-56, Session 15

BEaTriX: an expanded soft x-ray beam facility for test of focusing optics, an update

Carlo Pelliciari, Daniele Spiga, Giovanni Pareschi, Gianpiero Tagliaferri, INAF - Osservatorio Astronomico di Brera (Italy)

The BEaTRiX X-ray facility has been designed to test modular optics with very high angular resolution (FWHM < 3 arcsec). The main components of the facility are bremsstrahlung X-ray tubes, a parabolic mirror, a multi-reflection monochromator, an asymmetric Si(220) crystal to enlarge the beam and a CCD positioned in the focal plane (12 m). The setup is expected to generate a beam with a collimation of better than 1.8 arcsec and a section of 60x200 mm2. Other crystals and geometrical configuration are under study in order to extend the range to lower energies (1.5 keV). Simulation, Beatrix design and optical system are illustrated.

9603-57, Session 15

A Fresnel zone plate collimator: potential and aberrations

Benedikt Menz, Heinrich Brauninger, Vadim Burwitz, Gisela D. Hartner, Peter Predehl, Max-Planck-Institut für extraterrestrische Physik (Germany)

A collimator, that parallelizes an X-ray beam, provides a significant improvement of the metrology to characterize X-ray optics for satellite experiments at MPEs PANTER X-ray test facility. A Fresnel zone plate was selected as a collimating optic, as it meets a good angular resolution < 0.1" combined with a large active area > 10 cm^2.

Such an optic is ideally suited to illuminate Silicon Pore Optic (SPO) modules as proposed for ATHENA.

This paper provides the theoretic description of such a Fresnel zone plate

especially considering resolution and efficiency. Based on the theoretic results the collimator setup performance is analyzed and requirements for fabrication and alignment are calculated.

9603-58, Session 15

The characterization of mirror module for the qualification model of the ART-XC/SRG instrument

Alexey Tkachenko, Mikhail N. Pavlinsky, Alexander Yaskovich, Igor Y. Lapshov, Vladimir A. Oleynikov, Space Research Institute (Russian Federation); Sergey V. Grigorovich, Dmitriy Litvin, Valeriy P. Lazarchuk, Igor Roiz, Mikhail Garin, Russian Federal Nuclear Ctr. - All-Russian Research Institute of Experimental Physics (Russian Federation)

The Astronomical Roentgen Telescope – X-Ray Concentrator (ART-XC) is a medium-x-ray-energy survey instrument to be launched on board of the Spectrum Roentgen Gamma (SRG) Mission. The instrument consists of seven identical mirror modules coupled with seven CdTe strip focal-plane detectors. The ART-XC flight mirror modules have been developed and manufactured at the Marshall Space Flight Center (MSFC). VNIIEF (Sarov, Russia) has manufactured seven mirror modules for ART-XC qualification model. Some of these qualification mirror modules have been tested in x-rays at the Space Research Institute (Moscow, Russia) Stray Light Facility in order to develop measurement techniques and to clarify characteristics of mirror modules for fine-tuning technologies in future projects. Details of the characterization procedure and an overview of the obtained results are presented here.

SSUSI-Lite : a far-ultraviolet hyper-spectral imager for space weather remote sensing *(Invited Paper)*

Bernard S. Ogorzalek, Steve N. Osterman, John E. Hicks, Larry J. Paxton, Matthew P. Grey, Johns Hopkins Univ. Applied Physics Lab., LLC (United States)

SSUSI-Lite is a far-ultraviolet hyper-spectral imager for monitoring space weather. SSUSI-Lite is a refresh of the Special Sensor Ultraviolet Spectrographic Imager (SSUSI) that has flown on DMSP spacecraft F16 through F19. SSUSI-Lite maintains the same optical layout as the DMSP SSUSI, includes updates to key functional elements, and reduces the sensor volume, mass, and power requirements. We describe the re-design of the sensor, the improvements that have been made, and its measurement capabilities.

SSUSI-Lite generates images of the Earth's airglow in the far-ultraviolet by sweeping a mirror from horizon to horizon in the cross track direction at the input to the spectrograph. SSUSI-Lite contains an improved scanner design, which uses a pair of limited angle DC motors. The detector processing electronics, including pulse shaping and event binning, has been changed to all digital circuitry. The largest decrease in volume, mass, and power from the DMSP SSUSI has been obtained by consolidating all electronics into one data processing unit.

9604-2, Session 1

Stellar calibration of the special sensor ultraviolet limb imager (SSULI) on the DMSP spacecraft

Peter Walker, Computational Physics, Inc. (United States); Andrew C. Nicholas, Scott A. Budzien, Kenneth F. Dymond, Andrew W. Stephan, U.S. Naval Research Lab. (United States)

The SSULI (Special Sensor Ultraviolet Limb Imager) is a limb-scanning far- and extreme-ultraviolet spectrometer designed to fly on the Defense Meteorological Satellite Program (DMSP). The sensor sensitivity is tracked through the mission life by taking advantage of serendipitous stellar apparitions which, over the course of several days, track across the sensor's field of view, allowing for not only the production of a sensitivity curve when compared against the known stellar spectra, but additionally pointing information and field-of-view information can be gleaned from comparing the star's expected and observed positions. Most notably, because the star's apparition traces across the field of view predictably in one axis, and randomly in another, multiple apparitions of these point sources can be used to map out the gain on the detector's entire surface, revealing the existence and extent of localized gain sags. Additionally, multiple, routinized, and scheduled calibrations can be used to track sensor behavior through the mission life, including effects like a detector scrub, photocathode performance, and possible optics contamination. Results from the SSULI 002/DMSP F18 and SSULI 005/DMSP F19 stellar calibrations are presented.

9604-3, Session 1

WINCS on-orbit performance results

Andrew C. Nicholas, U.S. Naval Research Lab. (United States); Fred Herrero, Space Systems Research Corp. (United States); Andrew W. Stephan, Theodore Finne, U.S. Naval Research Lab. (United States)

The Winds-Ions-Neutral Composition Suite (WINCS) instrument, also know as the Small Wind and Temperature Spectrometer (SWATS), was designed and developed jointly by the Naval Research Laboratory (NRL) and NASA/ Goddard Space Flight Center (GSFC) for ionosphere-thermosphere investigations in orbit between 120 and 550 km altitude. The CubeSat compatible WINCS design provides the following measurements in a single package with a low Size, Weight, and Power (SWaP), 7.6 x 7.6 x 7.1 cm outer dimensions, 0.75 kg total mass, and about 1.3 Watt total power: neutral winds, neutral temperature, neutral density, neutral composition, ion drifts, ion temperature, ion density and ion composition. The instrument is currently operating on the International Space Station (Sep. 2013) and on the STP-Sat3 spacecraft (Nov. 2013). On-orbit results of the instrument will be presented along with a summary of future flight manifests.

9604-5, Session 1

Proton-electron discrimination detector (PEDD) for space weather monitoring

Chad M. Whitney, Erik B. Johnson, Xiao J. Chen, Christopher Stapels, Sam Vogel, James F. Christian, Radiation Monitoring Devices, Inc. (United States)

Electronics used for space applications (e.g. communication satellites) are susceptible to space weather, primarily consisting of electrons and protons. As more critical equipment is used in space, a comprehensive monitoring network is needed to mitigate risks associated with radiation damage. Compact detectors suited for this requirement have been too complicated or do not provide sufficient information. As the damage from electrons (e.g. total ionizing dose effects) is significantly different compared to protons (e.g. displacement damage effects), monitors that can provide unique measurements of the dose and/or spectral information for electrons and protons separately are necessary for mission assessment to determine strategies for maintaining function. Previously, we demonstrated that the Proton-Electron Discrimination Detector (PEDD) is space-compatible and can discriminate fast electrons from protons using a diphenylanthrecene (DPA) scintillator coupled to a CMOS solid-state photomultiplier (SSPM). The SSPM has a temperature dependence, and we will present a solution to this issue, providing a stable response as a function of temperature. The PEDD detector is scheduled to participate on the RHEME experiment to be flown on the ISS, scheduled for launch in 2016. The system will go live once powered, and we anticipate transmitting the acquired data from an FPGA system to the ISS in the form of 3, 32-bit integers per event containing information on the waveform integrals for proton-electron discrimination, event number, sensor temperature, and trigger amplitude. The latest results presented here expand on our previous work to include space-compatible packaging, temperature compensation for the SSPM, readout circuit design and specifications, and FPGA implementation.

9604-6, Session 1

South Atlantic anomaly and CubeSat design considerations

Judy A. Fennelly, William R. Johnston, Daniel M. Ober, Gordon R. Wilson, Air Force Research Lab. (United States); T. Paul O'Brien, The Aerospace Corp. (United States); Stuart L. Huston, Atmospheric and Environmental Research, Inc. (United States)

Effects of the South Atlantic Anomaly (SAA) on spacecraft in low Earth orbit (LEO) are well known and documented. The SAA exposes spacecraft in LEO to high doses of ionizing radiation as well as higher than normal rates of Single Event Upsets (SEU) and Single Event Latch-ups (SEL). CubeSats, spacecraft built around 10 x 10 cm cubes, are even more susceptible to

SEUs and SELs due to the use of commercial off-the-shelf components for electronics and payload instrumentation. Examination of the SAA using both data from the Defense Meteorological Satellite Program (DMSP) and a new set of models for the flux of particles is presented. The models, AE9, AP9, and SPM for energetic electrons, energetic protons and space plasma were developed for use in space system design. These models introduce data-based statistical constraints on the uncertainties from measurements and climatological variability. Discussion of the models' capabilities and limitations with regard to LEO CubSat design is presented.

9604-17, Session 2

Study of solar wind ions implantation effects in optical coatings in view of solar orbiter space mission operation

Davide Bacco, Alain Jody Corso, Univ. degli Studi di Padova (Italy); Enrico Tessarolo, IFN-CNR LUXOR Lab. (Italy); Enrico Napolitani, Univ. degli Studi di Padova (Italy); Paola Zuppella, IFN-CNR LUXOR Lab. (Italy); Francesca Gerlin, Marco Nardello, Univ. degli Studi di Padova (Italy); Silvano Fineschi, Ester Antonucci, INAF - Osservatorio Astronomico di Torino (Italy); Maria Guglielmina Pelizzo, IFN-CNR LUXOR Lab. (Italy)

Low energy ions coming from the quite solar wind are considered among causes of potential damage of the optical instrumentation and components on board of ESA Solar Orbiter. Predictions of space radiation parameters are available for instruments on board of such mission. Accelerators are commonly used to reproduce the particle irradiation on a spacecraft during its lifetime at the ground level. By selecting energies and equivalent doses it is possible to replicate the damage induced on space components. Implantation of Helium ions has been carried out on different single layer thin films at LEI facility at Forschungszentrum Dresden-Rossendorf varying the total dose. Profile of the implanted samples has been experimentally recovered by SIMS measurements. The change in reflectance performances of such coatings has been experimentally evaluated and modelled. The outcomes have been used to verify the potential impact on the METIS instrument and to drive the optimization of the M0 mirror coating.

9604-23, Session 2

Fabrication and testing of the Daniel K. Inouye Solar Telescope polarization optics

Erika K. Petrak, Meadowlark Optics, Inc. (United States); Stacey R. Sueoka, College of Optical Sciences, The Univ. of Arizona (United States); Thomas G. Baur, Meadowlark Optics, Inc. (United States)

Monitoring solar magnetic activity is an important function of the DKIST. This will be done by measuring the Stokes parameters with high polarimetric accuracy and precision over a broad wavelength range using polarization optics built at Meadowlark Optics. Six polarization assemblies, each 120mm in diameter, will measure these complex magnetic fields over 380nm-5,000nm. These assemblies are divided into three sub-spectrum specific pairs comprised of an achromatic calibration retarder and a poly-achromatic polarization modulator.

Each assembly contains six quartz or magnesium fluoride crystal waveplates. The optics' large aperture and materials choices enable full use of the 4-meter telescope's light collection but present a fabrication challenge. We have fine-tuned processes for precisely orienting and slicing magnesium fluoride needed for infrared polarimetry, and rigorously tested coupling materials that will minimize heating of these thermally sensitive, delicate crystals under the high solar flux of the DKIST. We have also developed techniques necessary to polish the assertive crystal symmetry of magnesium fluoride to difficult aspect ratios while maintaining required optical uniformity. We have achieved retardance uniformity of +0.01 waves at 633.4nm over each waveplate's 105mm clear aperture, measured with a precision of 0.0001 waves.

Our final assembly process ensures rotational alignment of all component waveplates to + 0.3 ?with low beam deviation and transmitted wavefront distortion. To validate the polarization performance of the optical assemblies, NSO will conduct Mueller matrix measurements at a number of wavelengths using a laboratory spectro-polarimeter. With these measurements we determine the performance of the retarders as calibration and modulator optics.

9604-25, Session 2

Investigation of contamination of thin-film aluminum filters by MMH-NTO plumes exposed to UV radiation

Vaibhav Gupta, Seth Wieman, Leonid Didkovsky, Space Sciences Ctr. (United States); Ralf Haiges, Wei Wu, Yuhan yao, Mike Gruntman, Dan Erwin, The Univ. of Southern California (United States)

Filter degradation accounts for 90% or more of the reduction in sensitivity that the EUV Spectrophotometer (ESP) onboard of the Solar Dynamics Observatory's (SDO) EUV Variability Experiment (EVE) and the Solar EUV Monitor (SEM) onboard of the Solar and Heliospheric Observatory (SOHO) have experienced in space. A possible cause for deterioration of the used thin-film Aluminum filters is contamination of their surfaces from plumes coming from periodic firing of their satellite's Monomethylhydrazine (MMH) – Nitrogen Tetroxide (NTO) thrusters. When adsorbed by the filters these contaminant molecules exposed to solar irradiance could lead to two possible compositions. First, they could get polymerized leading to a permanent hydrocarbon layer buildup on the filter's surface. Second, they could accelerate oxidation of filter's bulk Aluminum material internal to its most outer layers. To study the phenomenon we experimentally replicate contamination of such filters in a simulated environment by MMH-NTO plumes. We apply Atomic Force/Scanning Electron Microscopy and Raman/FTIR spectroscopy to characterize the physical and chemical changes on these contaminated sample filter surfaces and their layers. We then examine the processes involved in these interactions, specifically the role the UV radiation from our lab source plays in facilitating some underlying mechanisms. In addition, we present our first analysis of the effects of additional protective layer coatings based on self-assembled fluorinated Carbon monolayers for Aluminum filters. This coverage can significantly decrease these filter's susceptibility to contamination and reduce the overall degradation of filter based EUV instruments over their mission life.

9604-30, Session 2

First sub-arcsecond spectra covering solar chromosphere to corona: results from VERIS

Samuel D. Tun Beltran, Clarence M. Korendyke, Damien Chua, U.S. Naval Research Lab. (United States); Angelos Vourlidas, Applied Physics Lab. (United States)

We present the first results from the U.S. Naval Research Laboratory's (NRL's) VEry high angular Resolution Imaging Spectrometer (VERIS), launched from the White Sands Missile Range in New Mexico on August 8, 2013. It has obtained the first ever sub-arcsecond (0.2 arcsecond/pixel) spectrally pure images of transition region and coronal structures, directly addressing unresolved issues relating to interconnections of various temperature solar plasmas. VERIS' novel two-element, normal-incidence optical design with highly reflective EUV coatings give access to a spectral range with broad temperature range (0.03-15 MK) and density-sensitive lines emitted from the chromosphere to the corona. We discuss the instrument design, launch, and analysis of the He I (584 Å) slit-spectrum and 10x150 arcsecond image.

9604-7, Session 3

Design and modelisation of ASPIICS optics

Yvan G. Stockman, Camille Galy, Cedric Thizy, Etienne Renotte, Jean-Sébastien Servaye, Univ. de Liège (Belgium)

In the framework of development of ASPIICS (Association of Spacecraft for Polarimetric and Imaging Investigation of the Corona of the Sun), the Centre Spatial de Liege is responsible of the optical design of the coronagraph and the optics are manufactured by TOPTEC.

The particularity of this coronagraph is to have an external occulter located 150 m ahead a first imaging lens. This external occulter is re-imaged on an internal occulter. The function of this internal occulter is, as in a classical Lyot coronagraph, to block the sun light diffracted by the external Occulter and to reduce the straylight on the detector. The selection of this configuration is driven by the requirement to observe the corona as close as possible to the solar limb (i.e. 1 Rsun) without imaging the limb itself; a requirement of 1.08 Rsun is specified while 1.15 Rsun is the best performance currently reached by other space coronagraphs. The instrument is designed to have a field of view of 1.6° x 1.6° with a plate scale of 2.8 arcsec/pixel. Its performances are limited by diffraction in a 540 – 570 nm wavelength range.

This paper presents the optical design and demonstrates that the requirements are fulfilled by design and within the misalignment, manufacturing and thermo-elastic distortion errors.

9604-8, Session 3

Design status of ASPIICS, an externally occulted coronagraph for PROBA-3

Etienne Renotte, Andres Alia, Univ. de Liège (Belgium); Alessandro Bemporad, INAF - Osservatorio Astronomico di Torino (Italy); Joseph Bernier, Univ. de Liège (Belgium); Cristina Bramanti, European Space Research and Technology Ctr. (Netherlands); Steve Buckley, SensL (Ireland); Gerardo Capobianco, INAF - Osservatorio Astrofisico di Torino (Italy); Ileana Cernica, National Institute for Research and Development in Microtechnologies (Romania); Vladimir Dániel, Serenum a.s. (Czech Republic); Radoslav Darakchiev, Astri Polska Sp.z.o.o. (Poland); Marcin Darmetko, Centrum Bada? Kosmicznych Polskiej Akademii Nauk (Poland); Arnaud Debaize, François Denis, Univ. de Liège (Belgium); Richard Desselle, Univ. de Liège (Belgium); Lieve De Vos, OIP N.V. (Belgium); Adrian Dinescu, National Institute for Research and Development in Microtechnologies (Romania); Silvano Fineschi, INAF - Osservatorio Astronomico di Torino (Italy); Karl Fleury-Frenette, Univ. de Liège (Belgium); Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Aurélie Fumel, Univ. de Liège (Belgium); Damien Galano, European Space Research and Technology Ctr. Vit, Institute of Plasma Physics of the ASCR, v.v.i. (Czech Republic); Tomasz Walczak, Alicja Zarzycka, PCO S.A. (Poland); Joe Zender, European Space Research and Technology Ctr. (Netherlands); Andrei N. Zhukov, Royal Observatory of Belgium (Belgium)

The "sonic region" of the Sun corona remains extremely difficult to observe with spatial resolution and sensitivity sufficient to understand the fine scale phenomena that govern the quiescent solar corona, as well as phenomena that lead to coronal mass ejections (CMEs), which influence space weather. Improvement on this front requires eclipse-like conditions over long observation times. The space-borne coronagraphs flown so far provided a continuous coverage of the external parts of the corona but their over-occulting system did not permit to analyse the part of the white-light corona where the main coronal mass is concentrated. The proposed PROBA-3 Coronagraph System, also known as ASPIICS (Association of Spacecraft for Polarimetric and Imaging Investigation of the Corona of the Sun), with its

novel design, will be the first space coronagraph to cover the range of radial distances between 1.08 and 3 solar radii where the magnetic field plays a crucial role in the coronal dynamics, thus providing continuous observational conditions very close to those during a total solar eclipse.

PROBA-3 is first a mission devoted to the in-orbit demonstration of precise formation flying techniques and technologies for future European missions, which will fly ASPIICS as primary payload. The instrument is distributed over two satellites flying in formation (approx. 150m apart) to form a giant coronagraph capable of producing a nearly perfect eclipse allowing to observe the sun corona closer to the rim than ever before.

The coronagraph instrument is developed by a large European consortium including about 20 partners from 7 countries under the auspices of the European Space Agency. This paper is reviewing the recent improvements and design updates of the ASPIICS instrument as it is stepping into the detailed design phase.

9604-9, Session 3

The shadow positioning sensors (SPS) for formation flying metrology on-board the ESA-PROBA3 mission

Alessandro Bemporad, INAF - Osservatorio Astronomico di Torino (Italy); Gerardo Capobianco, INAF - Osservatorio Astrofisico di Torino (Italy); Silvano Fineschi, INAF - Osservatorio Astronomico di Torino (Italy); Mauro Focardi, Univ. of Florence (Italy) and INAF - Osservatorio Astrofisico di Arcetri (Italy); Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Davide Loreggia, Giuseppe Massone, INAF - Osservatorio Astronomico di Torino (Italy); Gianalfredo Nicolini, INAF - Osservatorio Astrofisico di Torino (Italy); Vladimiro Noce, INAF - Osservatorio Astrofisico di Arcetri (Italy); Maurizio Pancrazzi, Univ. of Florence (Italy); Marco Romoli, INAF - Osservatorio Astrofisico di Arcetri (Italy); Steve Buckley, Kevin O'Neill, SensL (Ireland)

PROBA3 is an ESA technology mission devoted to in-orbit demonstration of the formation flight (FF) technique, with two satellites kept at an average inter-distance by about 144 m. The ASPIIC instrument on-board PROBA3 will be the first ever space-based coronagraph working on one satellite and having the external occulter located on the second satellite, thus allowing observations of the inner solar corona with unprecedented reduction of stray light. During the observational periods, the FF configuration will be maintained with very high precision and two different techniques will be implemented: the use of Shadow Positioning Sensors (SPS) located on the Coronagraph Spacecraft (diodes measuring the penumbral light intensity on the entrance pupil plane) and the use of Occulter Position Sensor LEDs (OPSE) located on the back side of the Occulter Spacecraft. This paper will review the main instrumental requirements on the SPS needed to determine the 3-dimensional relative positioning of the two PROBA3 satellites with the high precision and frequency.

9604-10, Session 3

Formation flying metrology for the ESA-PROBA3 Mission: the shadow positioning sensors (SPS) silicon photomultipliers (SiPMs) readout electronics

Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Alessandro Bemporad, INAF - Osservatorio Astronomico di Torino (Italy); Steve Buckley, Kevin O'Neill, SensL (Ireland); Silvano Fineschi, INAF - Osservatorio Astronomico di Torino (Italy); Maurizio Pancrazzi, Federico Landini, Vladimiro Noce, Gerardo Capobianco, INAF - Osservatorio Astrofisico di Arcetri (Italy); Marco Romoli, Univ. degli Studi di Firenze (Italy); Davide Loreggia, Giuseppe Massone, INAF - Osservatorio Astronomico di Torino (Italy); Gianalfredo Nicolini, INAF - Osservatorio Astrofisico di Torino (Italy); Cedric Thizy, Etienne Renotte, Univ. de Liège (Belgium)

The European Space Agency is planning to launch in 2018 the PROBA3 Mission, designed to demonstrate the in-orbit formation flight (FF) attitude capability of its two satellites and to observe the inner part of the visible solar corona at the same time. The solar corona will be observed thanks to the presence on the first satellite facing the Sun of an external occulter producing an artificial eclipse of the Sun disk. The second satellite will carry on the coronagraph telescope and the digital camera system in order to perform imaging of the inner part of the corona, from 1.08 RSun up to about 3 RSun.

One of the main spacecraft devices used to control and to maintain the relative (i.e. between the two satellites) and absolute (i.e. with respect to the Sun) FF attitude is the Shadow Positioning Sensor (SPS) subsystem. It is composed of eight micro arrays of silicon photomultipliers (SiPMs) able to measure with the required sensitivity and dynamic range the penumbral light intensity on the Coronagraph entrance pupil. This paper will describe the overall SPS subsystem and its capability to satisfy the mission requirements from the light conversion process on board the silicon-based SPS devices up to the digital signal readout following both the amplification and analog to digital conversion stages.

9604-11, Session 3

Significance of the occulter diffraction for the PROBA3/ASPIICS formation flight metrology

Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Alessandro Bemporad, INAF - Osservatorio Astronomico di Torino (Italy); Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Silvano Fineschi, INAF - Osservatorio Astrofisico di Torino (Italy); Marco Romoli, Univ. degli Studi di Firenze (Italy); Maurizio Pancrazzi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Gerardo Capobianco, Davide Loreggia, Gianalfredo Nicolini, INAF - Osservatorio Astrofisico di Torino (Italy); Giuseppe Massone, INAF - Osservatorio Astronomico di Torino (Italy); Vladimiro Noce, INAF - Osservatorio Astrofisico di Arcetri (Italy); Cédric Thizy, Etienne Renotte, Univ. de Liège (Belgium)

PROBA3/ASPIICS is a formation flight coronagraph selected by ESA and currently in phase C/D.

It is constituted by two spacecrafts (one with the occulter, diameter 142 cm, and one with the telescope) separated by 144 m, kept in strict alignment by means of an active custom system. The alignment active system most critical components are the Shadow Positioning Sensors (SPS), a series of Si-PM (Silicon Photomultiplier) disposed around the telescope entrance aperture and measuring the pen-umbra generated by the occulter. The position of the SPSs is defined as a trade-off between mechanical constraints and maximum sensitivity to misalignments.

The diffraction generated by the occulter on the plane of the SPSs is not negligible respect to the pen-umbra intensity, and is mandatory to carefully evaluate its impact in order to refine the active alignment adjustment algorithm.

This work is dedicated to the description of the dedicated investigation that has been performed in order to evaluate the impact of the diffraction on the signal detected by the SPSs.

9604-13, Session 4

The extreme UV imager telescope on-board the Solar Orbiter Mission: overview of phase C and D

Jean-Philippe A. Halain, Pierre L. Rochus, Etienne Renotte, Aline Hermans, Lionel Jacques, Univ. de Liège (Belgium); Frédéric Auchère, Institut d'Astrophysique Spatiale (France); David Berghmans, Royal Observatory of Belgium (Belgium); Louise K. Harra, Mullard Space Science Lab. (United Kingdom); Udo H. Schühle, Max-Planck-Institut für Sonnensystemforschung (Germany); Werner K. Schmutz, Physikalisch-Meteorologisches Observatorium Davos (Switzerland); Andrei N. Zhukov, Royal Observatory of Belgium (Belgium); Regina Aznar Cuadrado, Max-Planck-Institut für Sonnensystemforschung (Germany); Franck Delmotte, Institut d'Optique Graduate School (France); Cydalise Dumesnil, Institut d'Astrophysique Spatiale (France); Manfred Gyo, Physikalisch-Meteorologisches Observatorium Davos (Switzerland); Thomas E. Kennedy, Philip J. Smith, Jason A. Tandy, Mullard Space Science Lab. (United Kingdom); Raymond F. Mercier, Institut d'Optique Graduate School (France); Francis Verbeeck, Royal Observatory of Belgium (Belgium)

The Solar Orbiter mission is composed of ten scientific instruments dedicated to the observation of the Sun's atmosphere and its heliosphere, taking advantage of an out-of ecliptic orbit and at perihelion reaching a proximity close to 0.28 A.U.

On board Solar Orbiter, the Extreme Ultraviolet Imager (EUI) will provide full-Sun image sequences of the solar corona in the extreme ultraviolet (17.1 nm and 30.4 nm), and high-resolution image sequences of the solar disk in the extreme ultraviolet (17.1 nm) and in the vacuum ultraviolet (121.6 nm).

The EUI concept uses heritage from previous similar extreme ultraviolet instrument. Additional constraints from the specific orbit (thermal and radiation environment, limited telemetry download) however required dedicated technologies to achieve the scientific objectives of the mission. We report on the development of CMOS-APS detectors, high reflectivity mirror coatings, heat pipe and highly efficient heat-rejection entrance baffles, data compression and prioritization, and re-closable door mechanisms.

The development phase C of the instrument and its sub-systems has been successfully completed, including thermo-mechanical and electrical design validations with the Structural Thermal Model (STM) and the Engineering Model (EM).

The instrument STM and EM units have been integrated on the respective spacecraft models and will undergo the system level tests. In parallel, the Phase D has been started with the sub-system qualifications and the flight part manufacturing.

The next step of the EUI development will be the instrument Qualification Model (QM) integration and qualification tests. The Flight Model (FM) instrument activities will then follow with the acceptance tests and calibration campaigns.

9604-14, Session 4

The extreme ultraviolet imager of solar orbiter: optical design and alignment scheme

Jean-Philippe A. Halain, Alexandra Mazzoli, Univ. de Liège (Belgium); Stefan Meining, Max-Planck-Institut für Sonnensystemforschung (Germany); Pierre L. Rochus, Etienne Renotte, Univ. de Liège (Belgium); Frédéric Auchère, Institut d'Astrophysique Spatiale (France); Udo H. Schühle, Max-Planck-Institut für Sonnensystemforschung (Germany); Franck Delmotte, Institut d'Optique Graduate School (France); Anne Philippon, Institut d'Astrophysique Spatiale (France); Raymond F. Mercier, Institut d'Optique Graduate School (France); Aline Hermans, Univ. de Liège (Belgium)

The Extreme Ultraviolet Imager (EUI) is one of the remote sensing instruments on-board the Solar Orbiter mission. It will provide dual-band full-Sun images of the solar corona in the extreme ultraviolet (17.1 nm and 30.4 nm), and high-resolution images of the solar disk in both extreme ultraviolet (17.1 nm) and vacuum ultraviolet (Lyman-alpha 121.6 nm).

The EUI optical design takes heritage of previous similar instruments. The Full Sun Imager (FSI) channel is a single-mirror Herschel design telescope. The two High Resolution Imager (HRI) channels are based on a two-mirror optical refractive scheme, one Ritchey-Chretien and one Gregory optical design for the EUV and the Lyman-alpha channels, respectively.

The spectral performances of the EUI channels are obtained thanks to dedicated mirror multilayer coatings and specific band-pass filters. The FSI channel uses a dual-band mirror coating combined with aluminum and zirconium band-pass filters. The HRI channels use optimized band-pass selection mirror coatings combined with aluminum band-pass filters and narrow band interference filters for Lyman-alpha.

The optical performances result from accurate mirror manufacturing tolerances and from a two-step alignment procedure. The primary mirrors are first co-aligned. The HRI secondary mirrors and focal planes positions are then adjusted to have an optimum interferometric cavity in each of these two channels. For that purpose a dedicated alignment test setup has been prepared, composed of a dummy focal plane assembly representing the detector position.

Before the alignment on the flight optical bench, the overall alignment method has been validated on a dummy bench using flight spare optics that then be aligned on the Qualification Model to be used for the system verification test and qualifications.

9604-15, Session 4

Off-pointing stray light effects analysis on solar orbiter/METIS coronagraph

Marco Romoli, Univ. degli Studi di Firenze (Italy); Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Silvano Fineschi, Ester Antonucci, INAF - Osservatorio Astronomico di Torino (Italy); John D. Moses, U.S. Naval Research Lab. (United States); Mauro Focardi, Maurizio Pancrazzi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Giampiero Naletto, Univ. degli Studi di Padova (Italy); Gianalfredo Nicolini, INAF - Osservatorio Astrofisico di Torino (Italy); Daniele Spadaro, INAF - Osservatorio Astrofisico di Catania (Italy); Vincenzo Andretta, INAF - Osservatorio Astronomico di Capodimonte (Italy)

The METIS coronagraph will provide a measurement of the linear polarization of the visible corona and imaging in the Ly-a HI 121.6 nm line. Furthermore, being the only instrument to provide full imaging of the solar corona, METIS will constitute a context reference for the whole mission. Coronagraphs are designed to operate Sun center pointed and, given Solar Orbiter limited mass and power budget, METIS cannot be equipped with a re-pointing mechanism. Therefore, the spacecraft off-pointings may have an impact on the instrument performance, ranging from a slight disturbance in the stray light pattern up to a complete observation inability.

A comprehensive analysis has been conducted on the impact of off-pointings on the METIS performance. After the definition of the tolerable off-pointing ranges for METIS and their influence on the instrument performance, an experimental activity was conducted on a METIS prototype in order to understand the dependence of the stray light pattern change on the off-pointing conditions.

9604-16, Session 4

Dependence of the polarimetric efficiencies of a polarization modulator based on liquid crystal variable retarder on angle of incidence for the solar orbiter mission

Pilar García Parejo, Alberto Alvarez-Herrero, INTA Instituto Nacional de Técnica Aeroespacial (Spain)

Liquid Crystals Variable Retarders used as light polarization modulators in ground-based polarimeters and ellipsometers is a well-known and mature technology. In aerospace applications, they present many advantages with respect to the traditional rotatory retardance plates, as they avoid the use of mechanisms and present low mass and low power consumption. LCVRs will be used in the polarization modulation packages of the instruments SO/PHI (Polarimetric and Helioseismic Imager) and METIS/COR (Multi Element Telescope for Imaging and Spectroscopy, Coronagraph) for the Solar Orbiter Mission of ESA. Coronagraphs are characterized by having wide field-of-views (FOV) compared to instruments designed to study solar magnetic structures which involves large incidence angles through the entire instrument. Specifically, the METIS polarization modulation package will have to work with collimated rays and angles of incidence up to ±7.0 deg. Polarization optics, in particular retarders, are sensitive to the angle of incidence as their retardance changes with the incident angle. Since the retardances during the polarization modulations are optimized for a particular angle of incidence, other angles reduce the signal-to-noise ratio of the instrument and therefore the polarimetric sensitivity. For this reason, a configuration of double-cell has been selected for the METIS polarization modulator allowing wide acceptance angles. In this work, the demodulation efficiencies of the METIS polarization modulation package based on LCVRs have been measured at the incident angles of METIS coronagraph in order to quantify the polarimetric efficiencies across the Field of View and hence the polarimetric sensitivity as result of using different angles of incidence.

9604-27, Session 4

Polarimetric visible-light imaging with the METIS coronagraph on solar orbiter

Silvano Fineschi, INAF - Osservatorio Astronomico di Torino (Italy); Gerardo Capobianco, INAF - Osservatorio Astrofisico di Torino (Italy); Matteo Marmonti, Optec S.p.A. (Italy); Paolo Sandri, CGS S.p.A. (Italy); Ester Antonucci, INAF - Osservatorio Astronomico di Torino (Italy); Marco Romoli, Univ. degli Studi di Firenze (Italy); Giampiero Naletto, Univ. degli Studi di Padova (Italy); Daniele Spadaro, INAF - Osservatorio Astrofisico di Catania (Italy)

The METIS coronagraph onboard the Solar Orbiter mission will have the unique opportunity of observing the solar outer atmosphere as close to the Sun as 0.3 A.U., and from up to 35? out-of-ecliptic. The telescope design of the METIS coronagraph includes two optical paths for i) broad-band imaging of the full corona in linearly polarized visible-light (VL: 580-640 nm); ii) narrow-band imaging of the full corona in the ultraviolet (UV) Lyman ? (121.6 nm).

The original METIS optical design departs from the classical optical design for visible-light, solar coronagraphs by combining an all-reflective telescope for both UV and VL imaging, and an inverted external occultation for minimizing the Sun-disk thermal load.

This presentation describes the optical design of the imaging polarimeter for the METIS VL paths. The linearly polarized brightness (pB) images of the K-corona are used to derive the density distribution of the coronal electrons. The pB modulation is performed with an electro-optic polarimeter based on liquid crystals. The requirements on the polarization sensitivity, and instrumental polarization control are described. The expected performances of the VL path are also presented.

9604-29, Session 4

Stray-light analyses of the METIS coronagraph on solar orbiter

Paolo Sandri, CGS S.p.A. (Italy); Silvano Fineschi, INAF - Osservatorio Astronomico di Torino (Italy); Marco Romoli, Univ. degli Studi di Firenze (Italy); Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Vania Da Deppo, IFN-CNR LUXOR Lab. (Italy); Fabio Frassetto, CNR-IFN UoS Padova (Italy); Giampiero Naletto, Univ. degli Studi di Padova (Italy); D. Moreau, CGS S.p.A. (Italy); Ester Antonucci, INAF - Osservatorio Astronomico di Torino (Italy); Daniele Spadaro, INAF - Osservatorio Astrofisico di Catania (Italy); Vincenzo Andretta, INAF - Osservatorio Astronomico di Capodimonte (Italy)

The METIS coronagraph on board the Solar Orbiter mission will have the unique opportunity of observing the solar outer atmosphere as close to the Sun as 0.28 A.U., and from up to 35? out-of-ecliptic. The telescope design of the METIS coronagraph includes two optical paths for i) broad-band imaging of the full corona in linearly polarized visible-light (VL: 580-640 nm); ii) narrow-band imaging of the full corona in the ultraviolet (UV) Lyman ? (121.6 nm).

The original METIS optical design departs from the classical optical design for visible-light, solar coronagraphs by combining an all-reflective telescope for both UV and VL imaging, and an inverted external occultation for minimizing the Sun-disk thermal load.

This presentation describes the stray-light analysis performed on the UV and VL channels of the METIS Telescope with the non-sequential modality of the software Zemax. A detailed opto-mechanical model of the METIS Telescope is simulated by placing the CAD parts of all the sub-assemblies, including the UV photocathode with its protective window, at the nominal position. Each surface, mechanical and optical, is provided with a property of reflection and/or transmission, absorption and scattering. The values inserted in the model reproduce the optical and the diffusing properties measured on representative samples.

The model allows for the verification of the correct functioning of the blocking elements inside the telescope. These elements are the baffle at the Shield Entrance Aperture (SEA), the Sun-disk light rejection mirror (M0=, the Lyot Stop, the Field Stop, the Internal Occulter and the annular diaphragm of the Collimating Doublet of the Polarimeter. These elements are in the most critical positions for the generation of diffuse light, with the Sun simulated at the distance of 0.28 AU from the instrument. The model allows also for an evaluation of the stray-light level on the sensitive area of the VL detector and of the UV detector. The results of the simulations are compared to the requirements of stray-light levels.

A simple model for including the effects of the diffraction off the inner edge of the IEO on the plane of the IO is also presented. In spite of the limitation to few millions of rays in the standard ray-tracing simulation, the model allows for an useful insight in the expected performances of the instrument. The results of this analysis compare well with those performed also with the ASAP optical software.

9604-18, Session 5

New scheme of international task shares of the Solar-C Mission

Tetsuya Watanabe, National Astronomical Observatory of Japan (Japan); Kiyoshi Ichimoto, Kyoto Univ. Hida Observatory (Japan); Kanya Kusano, Nagoya Univ. (Japan); Toshifumi Shimizu, Japan Aerospace Exploration Agency (Japan); Hirohisa Hara, National Astronomical Observatory of Japan (Japan); Taro Sakao, Japan Aerospace Exploration Agency (Japan); Yoshinori Suematsu, Yukio Katsukawa, National Astronomical Observatory of Japan

(Japan); Keisuke Yoshihara, Japan Aerospace Exploration Agency (Japan)

Solar-C is a Japanese-led international solar observing mission designed to answer some of the most important questions in solar physics. Recent progress achieved by space missions like Hinode has revealed that the different parts of the magnetized solar atmosphere are essentially coupled and has defined the spatial scales and temperature regimes that need to be observed in order to achieve a comprehensive physical understanding of this coupling. Solar-C will have on board a carefully coordinated suite of three major complementary instruments: the Solar Ultra-violet Visible and IR Telescope (SUVIT), accommodating three focal plane instruments; Spectropolarimeter (SP), Filtergraph (FG), and UV-Blue Imaging Spectrometer (UBIS), the High-throughput EUV Spectroscopic Telescope (EUVST) with an Irradiance Monitor, and a High-resolution Coronal Imager (HCI). The science of Solar-C will greatly advance our understanding of the Sun, of basic physical processes operating throughout the universe, and of how the Sun influences the Earth and other planets in our solar system.

9604-19, Session 5

Magnetic activity of the solar corona (MASC)

Frédéric Auchère, Institut d'Astrophysique Spatiale (France); Hui Li, Purple Mountain Observatory (China)

MASC is designed to answer the following top-level scientific questions:

1. What is the global magnetic field configuration in the corona?

2. What is the role of the magnetic field in the triggering of flares and CMEs?

3. What is the role of the magnetic field in the acceleration mechanisms of the solar winds?

4. What is the energy spectrum and in particular what are the highest energies to which charged particles can be accelerated in the solar corona?

MASC will address these fundamental questions with a suite of instruments composed of an X-ray spectrometer, a UV / EUV imager, and a coronagraph working in the visible and at Lyman alpha. The spectrometer will provide information on the energetics of solar flares, in particular at very high energies of accelerated particles. The UV / EUV imager will provide constraints on the temperature of the flaring and non-flaring corona. The coronagraph will provide the number density of free electrons in the corona, maps of the outflow velocity of neutral hydrogen, and measurements of the coronal magnetic field, via the Hanle effect. These measurements will be performed at all steps of the flare-CME processes, thus providing a detailed picture of the solar coronal dynamics in the quiet and eruptive periods.

9604-20, Session 5

Coronal and heliospheric imagers for solar wind phenomena

Kevin F. Middleton, Jackie A. Davies, Chris J. Eyles, Doug K. Griffin, Richard A. Harrison, S. James Tappin, Ian A. J. Tosh, Nick R. Waltham, STFC Rutherford Appleton Lab. (United Kingdom)

RAL Space is enhancing its programme to lead the development of European capabilities in visible-light coronal and heliospheric imaging instrumentation in the light of emerging opportunities such as the European Space Agency's Space Situational Awareness programme and S2 small-mission call. Visible-light coronal and heliospheric imaging of solar wind phenomena, such as coronal mass ejections and interaction regions, is of critical importance to space weather, both operationally and in terms of enabling the underpinning science. This work draws on heritage from scientific instruments such as LASCO (Large Angle and Spectrometric Coronagraph) on the SOHO spacecraft, the SMEI (Solar Mass Ejection Imager) on the Coriolis spacecraft and the HI (Heliospheric Imager) instruments on STEREO. Observation of solar wind structures relies on the detection of sunlight that has been Thomson-scattered from electrons (the so-called K-corona). The Thomson-scattered signal must be extracted from other signals that can be many orders of magnitude greater (such as that from the F-corona and the solar disc itself) and this places stringent constraints on stray-light rejection, as well as pointing stability and accuracy. We discuss the determination of instrument requirements, key design trade-offs and the evolution of base-line designs for the coronal and heliospheric regimes. We explain how the next generation of instruments will build on this heritage while also, in some cases, meeting the challenges on resources imposed on operational space weather imagers. In particular, we discuss the optical engineering challenges involved in the design of these instruments.

9604-21, Session 5

ASO-S: advanced space-based solar observatory

Weiqun Gan, Purple Mountain Observatory (China)

ASO-S is the mission proposed for the next solar maximum by the Chinese solar community. The scientific objectives are to study the relationships among solar magnetic field, solar flares, and coronal mass ejections. ASO-S is now undertaking the phase-B study. The talk will give a brief introduction of the mission.

9604-22, Session 5

The Bragg solar x-ray spectrometer SolpeX

Daniel ?cis?owski, Janusz Sylwester, Stefan P?ocieniak, Jaros?aw B?ka?a, ?aneta Szaforz, Marek St??licki, Miros?aw Kowali?ski, Piotr Podgórski, Jose Hernandez, Witold Trzebi?ski, Space Research Ctr. (Poland); Sergey V. Kuzin, Sergey V. Shestov, P.N. Lebedev Physical Institute (Russian Federation)

Detection of polarization and spectra of X-ray solar flare emission are indispensable in improving our understanding of the processes releasing energy of these most energetic phenomena in the solar system. We shall present some details of the construction of SolpeX - an innovative Bragg soft X-ray flare polarimeter and spectrometer. The instrument is a part of KORTES – Russian instrument complex to be mounted aboard the science module to be attached to the International Space Station (2017/2018).

The SolpeX will be composed of three individual measuring units: the soft X-ray polarimeter with 1-2% linear polarization detection threshold, a fast-rotating flat crystal X-ray spectrometer with a very high time resolution (0.1s) and a simple pin-hole soft X-ray imager-spectrometer with a moderate spatial (~20arcsec), spectral (0.5 keV) and high time resolution (0.1s). Having a fast rotating unit to be served with power, telemetry and "intelligence" poses a challenge for the designer. Some of the solutions to this challenge will be provided and described.

9604-24, Session 5

EUV multilayer coatings for solar imaging and spectroscopy

David L. Windt, Reflective X-Ray Optics LLC (United States)

Nanometer-scale multilayer coatings that provide high reflectance at normal incidence in the EUV have proven extremely valuable to current space-based solar research targeting this scientifically-important spectral region. EUV multilayers now constitute an essential, mission-enabling technology that is widely used for both imaging and spectroscopy. Multilayer-based instruments have been used in a number of major satellite instruments over the past two decades, and have flown in numerous sounding rocket experiments as well.

To successfully address the unresolved physics underlying coronal activity, future solar missions targeting the EUV that are now being formulated will require even higher spatial resolution and better signal-to-noise than has been achieved thus far in any satellite instrument, while supporting the exposure times and cadences necessary to capture the evolution of flares, jets, CMEs and other dynamic processes in the solar atmosphere. To meet these science requirements, new multilayer coatings will be needed that have higher reflectance, and either better spectral selectivity for narrow-band imaging, or broad spectral response for spectroscopy.

I will describe recent progress, and future prospects, in the development of new EUV multilayer coatings for solar physics. Specifically, I will describe the development of a variety of new high-performance multilayers for narrow-band EUV imaging, as well as the development of aperiodic multilayer coatings that can provide broad spectral response at normal incidence for EUV spectroscopy.

9604-26, Session 5

Hydrogen Lyman-alpha polarimeter for SCORE

Silvano Fineschi, INAF - Osservatorio Astronomico di Torino (Italy); John D. Moses, U.S. Naval Research Lab. (United States); Juan Ignacio Larruquert, Instituto de Óptica “Daza de Valdés” (Spain)

The linear polarization by resonance scattering of coronal permitted line-emission in the ultraviolet (UV) can be modified by magnetic fields through the Hanle effect. Space-based UV spectro-polarimeters would provide an additional tool for the diagnostics of coronal magnetism. As a case study of space-borne UV spectro-polarimeters, this presentation will describe the future upgrade of the Sounding-rocket Coronagraphic Experiment (SCORE) to include the capability of imaging polarimetry of the HI Lyman-?, 121.6 nm. SCORE is a multi-wavelength imager for the emission-lines, HeII 30.4 nm and HI 121.6 nm, and visible-light broad-band emission of the polarized K-corona.

SCORE has flown successfully in 2009. This presentation will describe how in future reflights SCORE could observe the expected Hanle effect in corona with a HI Lyman-? polarimeter. This UV polarimeter comprises a novel transmissive analyser with a narrow-band UV polarization coating. The polarization modulation is achieved by mechanically rotating a MgF2 half-wave plate.

9604-28, Session 5

Waves and magnetism in the solar atmosphere (WAMIS)

John D. Moses, Yuan-Kuen Ko, J. Martin Laming, Leonard Strachan, U.S. Naval Research Lab. (United States); Steven Tomczyk, National Ctr. for Atmospheric Research (United States); Frédéric Auchère, Institut d’Astrophysique Spatiale (France); Roberto Casini, National Ctr. for Atmospheric Research (United States); Silvano Fineschi, INAF - Osservatorio Astronomico di Torino (Italy); Sarah E. Gibson, Michael Knoelker, National Ctr. for Atmospheric Research (United States); Clarence M. Korendyke, U.S. Naval Research Lab. (United States); Scott McIntosh, National Ctr. for Atmospheric Research (United States); Marco Romoli, Univ. degli Studi di Firenze (Italy); Jan Rybak, Astronomical Institute (Slovakia); Dennis George Socker, U.S. Naval Research Lab. (United States); Angelos Vourlidas, Johns Hopkins Univ. (United States); Qian Wu, National Ctr. for Atmospheric Research (United States)

Since the advent of SOHO followed by TRACE and SDO, the solar atmosphere has come to be appreciated as an increasingly dynamic and complex environment. Waves play a much larger role in shaping the plasma properties than hitherto assumed and can have non-negligible energy densities compared to the thermal gas in the low ??corona. Various oscillation modes of coronal loops have been identified in observations. Compressive waves connected to slow mode or fast mode waves, or their analogs in non-homogeneous media, have been readily detected, but the non-compressive Alfvén wave has proven more elusive. Even so, the realization that Alfvén or fast mode (collectively referred to as ‘Alfvénic’) waves are ubiquitous in the solar upper atmosphere signifies an important new development with profound consequences for our understanding of the corona and solar wind. Comprehensive measurements of magnetic fields in the solar corona have a longer history as an important scientific goal. Besides being crucial to understanding and predicting the Sun’s generation of space weather, direct measurement of its strength and direction is also a crucial step in understanding observed wave motions. In this regard, the remote sensing instrumentation used to make magnetic field measurements is well suited to measuring the Doppler signature of waves in the solar structures. In this paper, we describe the design and scientific values of the WAMIS (Waves and Magnetism in the Solar Atmosphere) investigation. WAMIS, taking advantage of greatly improved infrared (IR) detectors, forward models, advanced diagnostic tools and inversion codes, is a long-duration high-altitude balloon payload designed to obtain a breakthrough in the measurement of coronal magnetic fields and in the understanding of the interaction of these fields with space plasmas. It consists of a 20 cm aperture coronagraph with an IR spectro-polarimeter focal plane assembly. The balloon altitude will provide minimum atmospheric absorption and scattering at the IR wavelengths in which these observations are made. WAMIS will obtain continuous measurements over at least two weeks of the strength and direction of coronal magnetic fields. These measurements will be made over a large field-of-view and at the spatial and temporal resolutions required to address several outstanding problems in coronal physics. Additionally, WAMIS will obtain near simultaneous observations of the electron scattered K-corona for context and to establish electron density. These comprehensive observations are not provided by any current single ground-based or space observatory.

9604-12, Session PMon

OPSE metrology system onboard of the PROBA3 mission of ESA

Davide Loreggia, Alessandro Bemporad, INAF - Osservatorio Astronomico di Torino (Italy); Gerardo Capobianco, Silvano Fineschi, INAF - Osservatorio Astrofisico di Torino (Italy); Mauro Focardi, Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Giuseppe Massone, Gianalfredo Nicolini, INAF - Osservatorio Astrofisico di Torino (Italy); Maurizio Pancrazi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Marco Romoli, INAF - Osservatorio Astronomico di Arcetri (Italy); Ileana Cernica, Munizer G. Purica, Elena Budianu, National Institute for Research and Development in Microtechnologies (Romania); Cedric Thizy, Etienne Renotte, Jean-Sébastien Servaye, CSL - Centre Spatial de Liège (Belgium)

In recent years, ESA has assessed several mission involving formation flying (FF). The great interest in this topic is mainly driven by the need for moving from ground to space the location of next generation astronomical telescopes overcoming most of the critical problems, as example the construction of huge baselines for interferometry. In this scenario, metrology systems play a critical role. PROBA3 is an ESA technology mission devoted to in-orbit demonstration of the FF technique, with two satellites, an occulter and a main satellite housing a coronagraph named ASPIICS, kept at an average inter-distance by about 144m, with micron scale accuracy. The guiding proposal is to test several metrology solution for spacecraft alignment, with the important scientific return of having observation of Corona at never reached before angular field. The Shadow Position Sensors (SPS), and the Optical Position Emitters Sensors (OPSE)

are two of the systems used for FF fine tracking. The SPS are finalized to monitor the position of the two spacecraft with respect to the Sun and are discussed in dedicated papers presented in this conference. The OPSE will monitor the relative position of the two satellites and consists of 3 emitters positioned on the rear surface of the occulter, that will be observed by the coronagraph itself. By following the evolution of the emitters images at the focal plane the alignment of the two spacecrafts is retrieved via dedicated centroiding algoritm. We present an overview of the OPSE system and of the centroiding approach.

9605-60, Session PMon

Fluoride fiber thermal emission study for SPIRou @ CFHT

Yoan Micheau, Marc Bouyé, Observatoire Midi-Pyrénées (France); Jérôme Parisot, Observatoire de Paris à Meudon (France); Driss Kouach, Observatoire Midi-Pyrénées (France)

SPIRou is a near-IR (0.98-2.35?m), echelle spectropolarimeter / high precision velocimeter being designed as a next-generation instrument for the 3.6m Canada-France-Hawaii Telescope on Mauna Kea, Hawaii, with the main goal of detecting Earth-like planets around low mass stars and magnetic fields of forming stars.

The SPIRou science fiber, which connects the polarimeter unit to the cryogenic spectrograph unit (35 meter apart), emits an undesirable thermal flux into the spectrograph, due to its intrinsic absorption.

This may degrade the signal to noise ratio and then the sensitivity of the instrument for the reddest wavelengths.

For verifying the calculation model used to predict the thermal emission from the SPIRou science fiber, a test bench is set-up at LESIA (Observatory of Paris).

In this paper, we described the experimental approach to measure the thermal emission from a 30 meter long fluoride fiber @3µm. Experimental results are then compared to those predicted by the theoretical model.

9605-61, Session PMon

A new fiber slit assembly for the foces spectrograph

Hanna Kellermann, Univ.-Sternwarte München (Germany); Frank U. Grupp, Univ.-Sternwarte München (Germany) and Max-Planck-Institut für extraterrestrische Physik (Germany); Christian Franik, Univ.-Sternwarte München (Germany); Anna Brucalassi, Max-Planck-Institut für extraterrestrische Physik (Germany); Florian Lang-Bardl, Ulrich Hopp, Univ.-Sternwarte München (Germany); Ralf Bender, Max-Planck-Institut für extraterrestrische Physik (Germany)

The R=70000 Echelle spectrograph at Wendelstein observatory will be equipped with a multi fibre slit allowing simultaneous calibration utilizing a Laser Frequency Comb as wavelength normal. The slit assembly consists of two multi-mode and two sigle-mode fibres. We will present fibre scrambling and optical image quality of the slit assembly. The four fibres will allow to test the spectrograph in the normal astronomical working condition with multi mode fibre coupling, and at the same time allow to test without fibre modal noise in the mono-mode configuration. As fibre modal noise is one of the dominant sources of insecurity in high precision radial velocity and planet detection spectroscopy the availability of mono-mode fibres allows to test the hardware chain in absence of modal noise.

9605-62, Session PMon

The replicable high-resolution exoplanet and asteroseismology (RHEA) spectrograph

Tobias Feger, Macquarie Univ. (Australia); Alexander Arriola Martiarena, Macquarie Univ. (Australia) and Ctr. for Ultrahigh Bandwidth Devices for Optical Systems (Australia); Izabela Spaleniak, Heriot-Watt Univ. (United Kingdom); Simon Gross, Macquarie Univ. (Australia) and Ctr. for Ultrahigh Bandwidth Devices for Optical Systems (Australia); Michael Ireland, The Australian National Univ. (Australia); David W. Coutts, Macquarie Univ. (Australia); Christian Schwab, Macquarie Univ. (Australia) and Australian Astronomical Observatory (Australia); Joao Bento, Macquarie Univ. (Australia)

RHEA is a compact single-mode spectrograph, designed to be used at modern-sized 0.2-1m class robotic telescopes, where long-term dedicated projects are feasible. The instrument will be primarily used for accurate radial velocity (RV) studies of low to intermediate-mass giant stars for the purpose of searching for hot Jupiters and using asteroseismology to simultaneously measure the host star parameters and de-correlate stellar pulsations. RHEA comprises a near-Littrow configuration and is mainly composed from off-the-shelf items with the aim of creating an inexpensive and replicable unit. The echelle format covers 47 spectral orders, spanning a wavelength range of 430-670 nm with minimum order separation of ?180 ?m. This separation allows the integration of a photonic lantern (PL) that converts incoherent light from a few-mode fiber into a series of 6 isolated diffraction-limited outputs. The PL chip eliminates modal noise and forms the entrance slit of the spectrograph. This enables an efficient and inherently stable instrument that Nyquist samples the line-spread function (LSF). In this paper we present a brief characterization of the laser-inscribed PL chip followed by results from on-sky testing at the Macquarie University Observatory.

9605-63, Session PMon

A white super-stable source for the metrology of astronomical photometers

François Wildi, Adrien Deline, Bruno Chazelas, Observatoire de Genève (Switzerland)

In the frame of the CHEOPS photometric transits mission, a calibration system has been developed that will allow measuring the absolute stability of the payload to a few ppm. One key element of this system is a white light source that is extremely accurately stabilized in flux.

This patent pending novel device is a very versatile building block that has applications in the characterization of all kind of photometers but is especially useful to test the performance of astronomical instruments dedicated to the photometric transit search. This paper addresses the design, the operation and the measured performance of this super-stable source.

9605-64, Session PMon

Design of the iLocater acquisition camera for the LBT

Andrew Bechter, Jonathan Crass, Ryan Ketterer, Justin R. Crepp, Univ. of Notre Dame (United States); David M. P. King, Univ. of Cambridge (United Kingdom); Robert O. Reynolds, Phil M. Hinz, The Univ. of Arizona (United States); Jack Brooks, Eric Bechter, Univ. of Notre Dame (United States); Bo Zhao, Univ. of Florida (United States); Christopher Matthews, Univ. of Notre Dame (United States)

Existing radial velocity instruments for planet detection are limited by

systematic errors resulting from their seeing-limited design. iLocater is an ultra-precise spectrometer that operates at the diffraction limit. Officially approved for installation at the Large Binocular Telescope, iLocater will search for Earth-like planets orbiting the nearest stars. We present the optical and mechanical design for iLocater's acquisition camera, which uses separate adaptive optics systems from two 8.4m telescopes to feed starlight into single mode fibers.

9605-65, Session PMon

Numerically designed phase-mask for stellar coronagraph

Naoshi Baba, Naoshi Murakami, Hokkaido Univ. (Japan); Noriaki Miura, Kitami Institute of Technology (Japan); Motohide Tamura, The Univ. of Tokyo (Japan)

Phase-mask coronagraph holds the ability to detect exoplanets at a distance of around 1 lambda/D from their parent star. Phase masks like a four-quadrant, an eight-octant, and a vortex types are shown to completely extinguish starlight for circular aperture telescopes. The problem here is that ordinary telescopes do not have perfect circular apertures but shades of a secondary mirror and spiders. It is known that shades of a secondary mirror and spiders deteriorate significantly the performance of phase-mask coronagraph. There have been proposed several ideas to overcome the deterioration. A pupil-remapping optical element is used to convert a secondary mirror obscured aperture to a clear circular one. A multistage vortex coronagraph is proposed to reduce the deterioration. Apodization to an entrance pupil has been shown effective to avoid the deterioration. However, these ideas are based on using theoretically established phase-masks.

We report a new kind of phase mask that performs the contrast ratio of more than the tenth power of 10 for a circular aperture with shades of a secondary mirror and spiders. The phase distribution of the phase mask is numerically obtained by letting the leaked light outside the transparent part of the pupil. The Lyot filter employed here is the same shape of the entrance pupil without any margin. We applied the hybrid input-output algorithm, one of phase retrieval methods, to find the phase distribution of the phase mask. We show the characteristics of thus obtained phase mask.

9605-66, Session PMon

Sparse aperture mask for low order wavefront sensing

Hari Subedi, Neil T. Zimmerman, N. Jeremy Kasdin, A. J. E. Riggs, Princeton Univ. (United States); Kathleen Cavanagh, SciTec, Inc. (United States)

A high contrast is required for direct imaging of exoplanets. Ideally, the level of contrast required for direct imaging of exoplanets can be achieved by coronagraphic imaging, but in practice, the contrast is degraded by wavefront aberrations. To achieve the required contrast, low-order wavefront aberrations such as tip-tilt, defocus and coma must be determined and corrected. In this paper, we present a technique that integrates a sparse-aperture mask (SAM) with a shaped pupil coronagraph (SPC) to make precise estimations of these low-order aberrations. Starlight rejected by the coronagraph's focal plane stop is collimated to a relay pupil, where the mask forms an interference fringe pattern on a detector. Using numerical simulations, we show that the SAM with optimized parameters: number of sub apertures, their radii and location can estimate rapidly varying tip-tilt errors in space telescopes arising from line-of-sight pointing oscillations as well as other higher order modes. At Princeton's High Contrast Imaging Laboratory, we have recently created a testbed devoted to low-order wavefront sensing experiments. The testbed incorporates custom-fabricated masks (shaped pupil, focal plane, and sparse aperture) with a deformable mirror and a CCD camera to demonstrate the estimation and correction of low-order aberrations. Our first experiments aim to replicate the results of the SAM WFS Fourier propagation models.

9605-67, Session PMon

Coronagraphic image analysis for tip-tilt retrieval applied to the vector vortex phase mask

Elsa Huby, Univ. de Liège (Belgium); Pierre Baudoz, Observatoire de Paris (France); Olivier Absil, Univ. de Liège (Belgium); Dimitri Mawet, California Institute of Technology (United States) and European Southern Observatory (Chile); Aïssa Jolivet, Univ. de Liège (Belgium); Garreth J. Ruane, Rochester Institute of Technology (United States); Brunella Carlomagno, Pierre Piron, Jean Surdej, Univ. de Liège (Belgium)

Small inner-working angle coronagraphs (1 to 4 lambda/D), such as the vector vortex phase mask, are very sensitive to low-order aberrations. In particular, decentering errors (tip-tilt aberrations) lead to leakage of the central star light and thus to a reduction of the contrast performance close to the star. Such pointing errors are often a consequence of mechanical flexures due to temperature variations, and may result in slow drifts that are not sensed by the AO system (non-common path errors). In order to improve the on-sky performance of these coronagraphs, we intend to implement post-coronagraphic low-order aberration sensing by direct analysis of coronagraphic images. This technique has been initially described by Mas et al. 2012 for retrieving the tip-tilt amount in the case of the four quadrant phase mask coronagraph. The asymmetry of the coronagraphic PSF is quantified by measuring the flux in four quadrants of the image plane detector and the differential flux along two orthogonal directions is derived. In the case of the vortex phase mask, we show that these quantities are directly linked to the amount of tip-tilt affecting the beam upstream of the coronagraphic mask. For that purpose, we have developed a Zernike-based analysis to model the response of the coronagraph in presence of aberrations. We present simulations and experimental results that validate this method in the case of an unobstructed circular pupil. This promising technique will be soon implemented on-sky, in the Keck/NIRC2 instrument for instance, where an AGPM vortex phase mask will be integrated in Spring 2015.

9605-68, Session PMon

High-contrast coronagraph performance in the presence of DM actuator defects

Erkin Sidick, Stuart B. Shaklan, Eric Cady, Jet Propulsion Lab. (United States)

Deformable Mirrors are critical elements in high contrast coronagraphs, requiring precision and stability measured in picometers to enable detection of Earth-like exoplanets. Occasionally DM actuators or their associated cables or electronics fail, requiring the wavefront control algorithm to compensate for actuators that may be displaced from their neighbors by hundreds of nanometers or more. We have carried out experiments on the HCIT testbed to study the impact of failed actuators in partial fulfilment of the Terrestrial Planet Finder Coronagraph optical model validation milestone. We show that the wavefront control algorithm adapts to several broken actuators and maintains dark hole contrast in broadband light.

9605-69, Session PMon

Development of focal plane phase masks for PIAACMC

Kevin E. Newman, Olivier Guyon, The Univ. of Arizona (United States); James W. Conway, Stanford Univ. (United States); Ruslan Belikov, NASA Ames Research Ctr. (United States)

The Phase Induced Amplitude Apodization Complex Mask Coronagraph (PIAACMC) is an architecture for directly observing extrasolar planets, and can achieve performance near the theoretical limits for any direct-detection instrument. PIAACMC can be designed for centrally-obscured and segmented apertures, which is particularly useful for next-generation telescopes. The PIAACMC architecture includes aspheric PIAA optics, and a complex phase-shifting focal plane mask that provides a pi phase shift to a portion of the on-axis starlight. The phase-shifted starlight is forced to interfere destructively with the un-shifted starlight, causing the starlight to be eliminated, and allowing a region for high-contrast imaging near the star.

The PIAACMC focal plane mask is composed of zones that are optimized for broadband operation. We discuss various mask design and optimization strategies, with an emphasis on choosing designs that are more favorable for the manufacturing process. We include a discussion of mask manufacturing techniques, manufacturing limits, and their impact on potential coronagraph performance. We show laboratory results from fabricated masks, and propose the next steps for developing broadband achromatic phase masks for coronagraphy.

9605-70, Session PMon

High performance PIAACMC-type coronagraph designs for centrally obscured and segmented apertures

Olivier Guyon, The Univ. of Arizona (United States); Brian D. Kern, Jet Propulsion Lab. (United States); Ruslan Belikov, Kevin E. Newman, Eugene A. Pluzhnik, NASA Ames Research Ctr. (United States)

The Phase-Induced Amplitude Apodization Complex Mask Coronagraph (PIAACMC) combines lossless pupil apodization by beam shaping with a complex amplitude circular focal plane mask. The focal plane is realized as a multi-zone mirror or transmissive optical element, allowing design optimization for broadband operation. We describe the design process for the PIAACMC, and show that it can be simultaneously optimized for broadband operation and tip-tilt jitter sensitivity. The second optimization is especially important on large telescopes, as nearby stars are partially resolved. The design process takes into account chromatic diffraction by the aperture's edges (spiders, gap between segments).

We show that PIAACMC is fully compatible with pupil shapes previously thought to be "unfriendly" for coronagraphs, and illustrate its potential with two example. First, we describe the 3rd generation PIAACMC for the centrally obscured 2.4m WFIRST-AFTA telescope, and discuss its technology maturity and expected scientific yield. Second, we show a PIAACMC design for a large segmented aperture representative of what a future large telescope aimed at characterizing habitable exoplanets. We also briefly discuss PIAACMC designs for less challenging ground-based applications.

9605-71, Session PMon

In-lab performance of the latest AGPMs (angular groove phase mask) and recent development of VODCA (vortex optical demonstrator for coronagraphic applications)

Aïssa Jolivet, Elsa Huby, Olivier Absil, Univ. de Liège (Belgium); Christian Delacroix, Ctr. de Recherche Astrophysique de Lyon (France); Serge Habraken, Univ. de Liège (Belgium); Dimitri Mawet, European Southern Observatory (Chile); Pierre Piron, Jean Surdej, Univ. de Liège (Belgium)

We first present in this poster coronagraphic test results obtained with the latest AGPMs (Angular Groove Phase Masks), the charge two vortex phase masks made of circular sub-wavelength gratings in diamond.

Some of the tests were performed at the JPL (Jet Propulsion Laboratory) on IRCT (Infrared Coronagraphic Testbed). Other tests were carried out at the Observatoire de Paris, on YACADIRE (the coronagraphic bench of LESIA).

We detail here some of the tests and corresponding results especially about the peak attenuation in the infrared. These AGPMs were optimized in the L-band (wavelengths between 3 and 4 μm).

In the last part, we also present the most recent developments of VODCA (Vortex Optical Demonstrator for Coronagraphic Applications), an optical bench designed at the University of Liège (Belgium) to operate in near- to mid-infrared wavelengths (1-5 μm).

This bench is dedicated to the future characterization of Vortex phase masks. In order to improve starlight cancellation, we shall implement different pre- and/or post-coronagraphic concepts, such as optimal apodisation and wavefront control by coronagraphic image analysis.

9605-72, Session PMon

Design of off-axis PIAACMC mirrors

Eugene A. Pluzhnik, NASA Ames Research Ctr. (United States); Olivier Guyon, The Univ. of Arizona (United States) and Subaru Telescope, National Astronomical Observatory of Japan (United States); Ruslan Belikov, Eduardo Bendek, NASA Ames Research Ctr. (United States)

The Phase-Induced Amplitude Apodization Complex Mask Coronagraph (PIAACMC) provides an efficient way to control diffraction propagation effects caused by the central obstruction/segmented mirrors of the telescope. The PIAACMC can be optimized in a way that takes into account both chromatic diffraction effects caused by the telescope aperture and tip/tilt sensitivity of the coronagraph. As a result, in comparison with the original PIAA design, the PIAACMC mirror shapes appear to be asymmetric even for an on-axis coronagraph and require more care in calculating real off-axis shapes.

A method to design off-axis PIAA optics given known on-axis mirror shapes and remapping function is presented. The algorithm is based on geometrical ray tracing and is able to calculate off-axis PIAA mirror shapes for an arbitrary geometry of the input and output beams. The method is demonstrated with the third generation of the PIAACMC for WFIRST-AFTA telescope. Geometrical optics design issues related to the off-axis diffraction propagation effects are also discussed.

9605-73, Session PMon

Design and performance simulations of mid-IR AGPMs for ELT/METIS applications

Brunella Carlomagno, Univ. de Liège (Belgium); Christian Delacroix, Ctr. de Recherche Astrophysique de Lyon (France); Elsa Huby, Olivier Absil, Univ. de Liège (Belgium); Dimitri Mawet, European Southern Observatory (Chile); Aïssa Jolivet, Univ. de Liège (Belgium); Mikael Karlsson, Pontus Forsberg, Ernesto Vargas, Uppsala Univ. (Sweden); Serge Habraken, Jean Surdej, Univ. de Liège (Belgium)

The direct detection of exoplanets requires the use of dedicated, high contrast imaging instruments. In this context, vector vortex coronagraphs (VVCs) are considered to be among the most promising solutions to reach high contrast at small angular separations. They feature a small inner working angle (down to 0.9 lambda/D), high throughput, clear off-axis 360° discovery space, and are simple to implement. The AGPM (Annular Groove Phase Mask) is an implementation of the vortex phase mask, which provides achromaticity over an appreciable spectral range thanks to the use of sub-wavelength gratings. The grating profile can be optimized based on the rigorous coupled wave analysis (RCWA) to achieve a quasi-achromatic phase shift up to a very broad band (L+M band: 3.5-5.1μm). These devices have been manufactured onto CVD diamond substrates, using reactive ion etching. In this communication, I will first present the latest RCWA

simulations performed in the L, M and N spectral bands, and for some combinations of these bands. The resulting optimized AGPMs could be perfectly integrated in the E-ELT/METIS instrument, which aims at detecting and characterizing exoplanets by direct imaging. The target contrast for METIS is <1e-4 at 2 lambda/D (~40 mas in L band), which translates into a peak rejection rate of few hundreds for the AGPMs. Secondly, the optical propagation within the METIS instrument will be studied to determine the performances of a vortex coronagraph at the focus of METIS. In particular, the effect of the central obstruction, spiders, missing E-ELT segments, and pointing jitter will be analysed, together with the sensitivity to tip-tilt. Finally, the atmosphere and the AO contributions will be considered to obtain more realistic results.

PISCES: high contrast integral field spectrograph simulations and data reduction pipeline

Jorge Domingo Llop Sayson, The Catholic Univ. of America (United States); Nargess Memarsadeghi, Michael McElwain, NASA Goddard Space Flight Ctr. (United States); Marshall Perrin, Space Telescope Science Institute (United States); Qian Gong, NASA Goddard Space Flight Ctr. (United States); Bryan Grammer, SGT, Inc. (United States) and NASA Goddard Space Flight Ctr. (United States); Bradford W. Greeley, NASA Goddard Space Flight Ctr. (United States); George M. Hilton, Universities Space Research Association (United States) and NASA Goddard Space Flight Ctr. (United States); Catherine T. Marx, NASA Goddard Space Flight Ctr. (United States)

PISCES (Prototype Imaging Spectrograph for Coronagraphic Exoplanet Studies) is a lenslet array based integral field spectrograph (IFS) meant to advance the technology readiness of the WFIRST/AFTA high contrast Coronagraph Instrument. An optical simulator based on the IDL-based PROPER library for PISCES, as well as the Data Reduction Pipeline (DRP) are presented. The IFS simulations of the propagation of light are designed to probe the ability to preserve high contrast in the final data product. The DRP enables transformation of IFS data to calibrated spectral data cubes that are used to both validate the instrument requirements and predict the instrument performance.

9605-75, Session PMon

Maturing CCD photon counting technology for space flight

Udayan Mallik, Richard G. Lyon, Michael McElwain, Dominic J. Benford, Mark Clampin, Brian A. Hicks, NASA Goddard Space Flight Ctr. (United States)

Exo-planets are ultra low-light objects in space. Reflected terrestrial exo-planet light is 10^10-10^11 times fainter than the light of its parent star over a targeted spectral range of 450-950nm. This wavelength spectrum is of interest for spectroscopic characterization of exo-planet atmospheres. A space-based ~10 m aperture telescope will collect light from a terrestrial sized exo-planet around a nearby star at the rate of ~0.1photon/sec. Coronagraphic instruments are used to suppress starlight and image planet light with single photon counting cameras. A Visible Nulling Coronagraph (VNC) is an interferometric system for directly imaging exo-planets. It uses a high-speed, image feedback based active control system to sense and suppress residual starlight to a level below the brightness of the exo-planet. Imaging terrestrial exo-planets using a VNC, therefore, requires the ability to image single photon events at high frame-rates.

Electron Multiplying Charge Coupled Devices (EMCCDs) have a high Quantum Efficiency and low Read Noise. They are good detector candidates for instruments that image exo-planets. EMCCDs, however, suffer from a phenomenon called Clock Induced Charge (CIC) where energy from clock signals knock off valence electrons into the signal chain and generate an image signal which was not the result of integration of light. This effect is amplified in high-speed cameras. Herein, we present results from a shaped clock signal generator for EMCCDs which can control the energy distribution of the clock signal and limit CIC. The presented clock generator architecture can be easily modified for space by using appropriately qualified parts.

9605-76, Session PMon

Technological progress of a ferrofluid deformable mirror with tunable nominal optical power for high-contrast imaging

Aaron J. Lemmer, Tyler D. Groff, N. Jeremy Kasdin, Princeton Univ. (United States)

The success of a space-borne direct-imaging mission pursuing earth-sized exoplanets in the habitable zone hinges on the ability to achieve high contrast over a maximum field of view. Coronagraphic instruments designed to address this challenge suffer from optical aberrations and rely on focal-plane wavefront control to suppress the resulting speckles and widen the search area. Even small-featured quasi-static speckles---which may obscure or be confused with a planet---must be suppressed to the order of 10^{-10} over the search region, placing extreme demands on the deformable mirrors (DMs) used to implement the closed-loop control, both in wavefront requirements and actuation resolution. The ideal DM for focal-plane wavefront control has high surface quality and is capable of high-precision, low-stroke actuation. Conventional mirror technologies such as MEMS DMs, with heritage in ground-based adaptive optics instruments that correct for dynamic atmosphere-induced aberrations, are nominally flat and provide high-stroke, high-resolution control but at a cost of precision and surface quality. We present a new technology currently under development at Princeton, which features a ferrofluid-supported optical surface with local magnetic actuation. The actuation is transferred to the optical surface through a liquid medium which continuously supports it, decoupling the nominal surface profile from the actuator configuration and eliminating quilting. Additionally, the device carries nominal optical power via pneumatic control of the ferrofluid pressure, permitting a degree of high-fidelity low-order wavefront control impossible with current instrumentation. We report on the continuing technological growth of the prototype device, including progress with actuation, metrology, and modeling of the DM response.

9605-77, Session PMon

Wavefront sensing with pupil diversity using science hardware

Anand Sivaramakrishnan, Space Telescope Science Institute (United States); Alexandra Z. Greenbaum, Johns Hopkins Univ. (United States)

We combine in-focus images through a full pupil and a non-redundant mask (NRM) to provide a wavefront sensor (WFS). Utilizing filters and pupil masks designed solely for science, we create a WFS for future space telescopes, and obviate the necessity of flying some specialized WFS hardware. We use JWST's NIRISS NRM geometry and a full circular pupil in our demonstration, which includes photon noise, the fundamental limiting factor of this approach.

We also quantitatively investigate Fizeau-based approaches to a photon noise-limited wavefront stability monitor. The latter may be useful for very high contrast coronagraphic observations that utilize a bright WFS star prior to observing a coronagraphic target.

9605-78, Session PMon

Two DM probe test for high-contrast wavefront estimation

Christopher C. Veto, A. J. Eldorado Riggs, Neil T. Zimmerman, Tyler D. Groff, N. Jeremy Kasdin, Princeton Univ. (United States)

Motivated by the success of transit surveys such as Kepler, ground-based instruments for imaging warm, Jupiter-sized exoplanets, and the upcoming WFIRST/AFTA mission, progress towards a space-based coronagraph system that can create extremely dark, high-contrast regions in the PSF where Super-Earths to mini-Neptunes may be observed has accelerated. All coronagraphs require wavefront correction to re-gain regions of high star-to-plant contrast by correcting for aberrations in the electric field using estimation and control logic. Most current lab tests use model-based deformable mirror (DM) diversity type algorithms for wavefront estimation. Unfortunately, model uncertainties in the system (including assuming incorrect spatial frequencies which may cause energy to be unintendedly distributed) and in each DM's influence function shape limit the estimation accuracy. This paper presents a new approach for in situ calibration of the DM surface models. Assuming two sequential DMs for control, we refine the actuator-voltage-to-surface-map of each DM by iterating back and forth between which DM is probed and measure the resulting change in the electric field. By alternating DMs and iterating, there is sufficient information to accurately model the change in electric field for each shape applied to the deformable mirrors. The resulting field can then be used in the same estimation and control algorithms, resulting in more accurate estimates and more effective control. Here we present the results of our calibration algorithm in both simulation and experiment.

9605-79, Session PMon

Zernike wavefront sensor (ZWFS) modeling development for low order wavefront sensing (LOWFS) on wide-field IR space telescope (WFIRST) / astrophysics focused telescope assets (AFTA)

Xu Wang, J.Kent Wallace, Fang Shi, Jet Propulsion Lab. (United States)

WFIRST/AFTA design makes use of an existing 2.4m telescope for direct imaging of exoplanets. To keep the high contrast needed for the coronagraph, wavefront error (WFE) of the optical system needs to be continuously sensed and controlled. LOWFS uses the rejected starlight from an intermediate focal plane to sense wavefront changes (mostly thermally induced low order WFE) by combining the LOWFS mask (a phase plate located at the small center region with reflective layer) with the starlight rejection masks, i.e. Hybrid Lyot Coronagraph (HLC)'s occulter or Shaped Pupil Coronagraph (SPC)'s field stop. ZWFS measures phase via the phase-contrast method and is known to be photon noise optimal for measuring low order aberrations. Recently, ZWFS was selected as the baseline LOWFS technology on WFIST/AFTA for its good sensitivity, accuracy, and its easy integration with the starlight rejection mask. In this paper, we review the theory of ZWFS operation, describe the ZWFS algorithm development, and summarize various numerical sensitivity studies as well as WFS performance with AFTA pupil configurations (HLC/SPC) and the baseline CCD camera (CCD39 from E2V). We also show preliminary ZWFS model validation experiment results from the fabricated ZWFS phase mask on a stand-alone LOWFS testbed.

Deconvolution of differential OTF (dOTF) to measure high-resolution wavefront structure

Justin M. Knight, Kelsey L. Miller, Alexander T. Rodack, Johanan L. Codona, Olivier Guyon, The Univ. of Arizona (United States)

Differential OTF [Codona, Opt. Eng. 0001;52(9):097105-097105. doi:10.1117/1.OE.52.9.097105] uses two images taken with a telescope pupil modification between them to measure the complex field over most of the pupil. If the pupil modification involves a non-negligible region of the pupil, the dOTF field is blurred by convolution with the complex conjugate of the pupil field change. In some cases, such as using actuation of a primary mirror segment to make the measurement, the blurring can be significant [Codona & Doble, JATIS, 2015]. We explore using deconvolution to recover a higher-resolution measurement of the complex pupil field. We show that by masking off the redundant and overlapping parts of the dOTF and Fourier transforming back into image space, we have the complex diffraction field from the full pupil multiplied by the conjugate of the diffraction field from the modified part of the pupil. By assuming we know something about the area and nature of the difference field, we can construct a Wiener filter that gives a better estimate of the pupil field. We explore the use of constraints, such as zero dOTF amplitude beyond the edge of the pupil, to achieve a more robust result. We will present the theory, numerical simulations, and laboratory experiments to demonstrate the method. Our results for this paper are appropriate for narrowband measurements where the proportional radial blurring can be ignored over the entire dOTF result. We will show the effect of naively using this technique on a broadband dOTF measurement.

9605-81, Session PMon

UA wavefront control lab: design overview and implementation of new wavefront sensing techniques

Kelsey L. Miller, Justin M. Knight, Alexander T. Rodack, Johanan L. Codona, Olivier Guyon, The Univ. of Arizona, Steward Observatory (United States)

We present a new testbed designed to study coronagraphic imaging and wavefront control using a variety of pupil and coronagraph architectures. The testbed is designed to explore optimal use of starlight (including starlight rejected by the coronagraph) for wavefront control, system self-calibration, and point spread function (PSF) calibration. It is also compatible with coronagraph designs for centrally obscured and segmented apertures, and includes shaped or apodized pupils, a range of focal plane masks and Lyot stops of multiple sizes, and an optional PIAA apodizing stage. Starlight is reflected and imaged from the focal plane mask and Lyot stop for low-order wavefront sensing. Both a segmented and a continuous sheet MEMS DM are included to simulate segmented telescope pupils, apply known test phase patterns, and implement a controllable phase apodization coronagraph. The testbed is flexible and is used for exploring new and innovative techniques in wavefront sensing and PSF calibration, and coronagraph design. We describe how the testbed is currently being used to investigate three different techniques: (1) low-order wavefront sensing (LOWFS) using the light rejected by a hybrid-Lyot coronagraph, (2) linear dark field control (LDFC), and (3) the differential optical transfer function (dOTF) using displacements of the pupil segments to correct aberrations and enhance coronagraph performance.

9605-82, Session PMon

Adaptive optics self-calibration using differential OTF (dOTF)

Alexander T. Rodack, Justin M. Knight, Kelsey L. Miller,

Johanan L. Codona, The Univ. of Arizona (United States); Olivier Guyon, Subaru Telescope, National Astronomical Observatory of Japan (United States)

We demonstrate self-calibration of an adaptive optical system using Differential OTF [Codona JL; Opt. Eng. 0001;52(9):097105-097105. doi:10.1117/1.OE.52.9.097105]. We use a deformable mirror (DM) along with science camera focal plane images to implement a closed-loop servo that both flattens the DM and corrects for non-common-path aberrations within the telescope. The pupil field modification required for the dOTF measurement is introduced by displacing actuators near the edge of the illuminated pupil. We tested both an Iris AO hexagonal segmented MEMS DM and a Boston Micromachines continuous sheet MEMS DM. We normally compute the actuator correction updates directly from the phase of the dOTF measurements, reading out displacements and slopes at segment and actuator positions. We also note that since the dOTF is a linear combination of unmodified and modified pupil plane images, it is possible to build a reconstructor matrix that directly takes a vector of pixel values and outputs actuator updates. We explore the effectiveness of these techniques for a variety of bandwidths and number of photons collected in each dOTF exposure pair. We also explore the possibility of using the DM to intentionally add defocus during calibration to allow more photons to be captured in a single exposure without saturation.

9605-83, Session PMon

Control design for momentum-compensated fast steering mirror for WFIRST/AFTA coronagraph instrument

Brent E. Tweddle, Keith Patterson, Joel F. Shields, Xu Wang, Paul B. Brugarolas, Fang Shi, Jet Propulsion Lab. (United States)

This poster will present results of the feedback control design for JPL's Fast Steering Mirror (FSM) for the WFIRST/AFTA coronagraph instrument. The objective of this controller is to cancel jitter disturbances in the beam from the spacecraft to a pointing stability of 0.4 masec over the duration of the observation using a momentum-compensated FSM. The plant model for the FSM was characterized experimentally, and the sensor model is based on simulated results. The controller was designed using discrete-time pole placement techniques and simulated in Matlab with both feedback and disturbance feedforward control. This poster will present all aspects of the controller design, simulation and testing. Estimations of coronagraph contrast performance improvement based on a sensitivities model will also be presented.

9605-84, Session PMon

Design of a laboratory tesbed for external occulters at flight Fresnel numbers

Yunjong Kim, Michael Galvin, N. Jeremy Kasdin, Robert J. Vanderbei, Princeton Univ. (United States); Dongok Ryu, Sug-Whan Kim, Yonsei Univ. (Korea, Republic of); Dan Sirbu, NASA Ames Research Ctr. (United States)

Most extra planets are detected by using indirect observation such as the radial velocity method, transit photometry, and microlensing. There is increasing interest lately in the atmospheric composition of extra planets and in the discovery of bio-signatures. Information about extra planets can be obtained by direct observation. However, the main problem with the direct observation of extra planets is that the planet is 10^10 fainter than the parent star and the angular separation between the parent star and the planet is minimal. To distinguish the light between the extra planet and the parent star, a mask is needed to block the light of the parent star. An external occulter is a spacecraft flown along the line-of-sight of a space telescope to suppress starlight and enable high-contrast direct imaging of exoplanets. Laboratory verification of occulter designs is necessary to validate the optical models used to design and predict occulter performance. At Princeton, we are designing and building a testbed that allows verification of scaled occulter designs whose suppressed shadow is mathematically identical to that of space occulters. Here, we present a sample design operating at a flight Fresnel number and is thus representative of a realistic space mission. We will present the mechanical design of the testbed and simulations predicted the ultimate contrast performance. We will also present progress in implementation and preliminary results.

9605-85, Session PMon

External occulter edge scattering control using metamaterials for exoplanet detection

Eduardo A. Bendek, Dan Sirbu, NASA Ames Research Ctr. (United States); Zhaowei Liu, Univ. of California, San Diego (United States); Stefan R. Martin, Jet Propulsion Lab. (United States)

Direct imaging of earth-like exoplanets in the Habitable Zone of sun-like stars requires image contrast of ~10^10 at angular separations of around a hundred milliarcseconds. One approach for achieving this performance is to fly a starshade at a long distance in front of the telescope, shading the telescope from the direct starlight, but allowing planets around the star to be seen. The starshade is positioned so that sunlight falls on the surface away from the telescope, so it is not directly illuminated by the sun. However, sunlight scattered from the starshade edge can enter the telescope, raising the background light level and potentially preventing the starshade from delivering the required contrast. As a result, starshade edge design has been identified as one of the highest priority technology gaps for external occulter missions in the NASAs Exoplanet Exploration Program Technology Plan 2013. To reduce the sunlight edge scatter to an acceptable level, the edge radius of curvature (ROC) should be 1?m or less (commercial razor blades have ROC of a few hundred nanometer). This poses a challenging manufacturing requirement and may make the occulter difficult to handle. In this paper we propose an alternative approach to controlling the edge scattering by applying a flexible metamaterial to the occulter edge. Metamaterials are artificially structured materials, which have been designed to display properties not found in natural materials. Metamaterials can be designed to direct the scatter at planned incident angles away from the space telescope, thereby directly decreasing the contaminating background light.Reduction of the background light translates into shorter integration time to characterize a target planet and therefore improves the efficiency of the observations. As an additional benefit, metamaterials also have potential to produce increased tolerance to edge defects.

9605-86, Session PMon

Scaling relation for occulter manufacturing errors

Dan Sirbu, NASA Ames Research Ctr. (United States); N. Jeremy Kasdin, Robert J. Vanderbei, Princeton Univ. (United States)

An external occulter, or a starshade, is a spacecraft flown along the line-of-sight of a space telescope to suppress starlight and enable high-contrast direct imaging of exoplanets. The shape of an external occulter must be specially designed to optimally suppress starlight and deviations from the ideal shape due to manufacturing errors can result loss of suppression of the shadow. Due to the large dimensions involved for a space occulter, laboratory testing is conducted with scaled versions of occulters. Using numerical simulations for a flight Fresnel occulter design, we investigate suppression and contrast performance scaling for various levels of fixed feature-sizes.

9605-87, Session PMon

Astrometry with JWST-NIRISS AMI cryovac data

Deepashri Thatte, Space Telescope Science Institute (United States); Alexandra Z. Greenbaum, Johns Hopkins Univ. (United States); André R. Martel, Space Telescope Science Institute (United States); Étienne Artigau, Univ. de Montréal (Canada); Anand Sivaramakrishnan, Space Telescope Science Institute (United States)

JWST/NIRISS has a non-redundant aperture mask (NRM) for use with its F380M, F430M, F480M and F277W filters. In addition to high-resolution imaging with moderate contrast, the NRM provides better astrometric accuracy over a wide field than regular imaging. We investigate the accuracy achievable with the NRM by using an image-plane algorithm to analyze the PSFs of a point source that were obtained at a fixed pixel with sub-pixel dithers during the second Cryo-Vacuum test campaign. Astrometry of brown dwarfs with the NRM will be sensitive to terrestrial planets and used to probe the architecture of planetary systems around these objects.

9605-88, Session PMon

A method to directly image exoplanets in multi-star systems such as Alpha-Centauri

Sandrine J. Thomas, Ruslan Belikov, Eduardo A. Bendek, NASA Ames Research Ctr. (United States)

During the past year, extra-solar planets hunters witnessed the deployment and commissioning of the first generation of specialized ground-based exo-planets direct imaging instruments such as the Gemini Planet Imager and SPHERE. These systems allow detection and characterization of Jupiter-like planets 107 times fainter than their host star. Obtaining such contrast level and beyond requires a coronagraph to suppress light coming from the host star, a wavefront control system including a deformable mirror (DM) to remove residual light or speckles.

However, all these current as well as future systems focus on detecting faint planets around a single or unresolved binaries/multiples star systems in within a very small field of view (~2"). The limitations are (1) the incoherent light pollution of the companion(s) in the region of interest; (2) the degrees of freedom of the correcting devices are thought to be unable to correct for such polluting light.

Several planet candidates though are located around binary stars such as our neighboring star Alpha Centauri.

We showed in a previous SPIE paper our capability of creating a dark region around a single star outside the control region of the DM (beyond its half-Nyquist frequency), by taking advantage of aliasing effects. In this paper, we present a method to simultaneously correct aberrations and diffraction of light coming from the target star as well as its companion star in order to reveal planets orbiting the target star, both in within and outside the half-Nyquist region.

9605-89, Session PMon

Modeling of planetary signal detection through ray-tracing based beam propagation

Dongok Ryu, Sug-Whan Kim, Yonsei Univ. (Korea, Republic of)

High contrast images of exoplanet are limited by diffraction from optical and opto-mechanical components of instrumentation. Therefore it needs optimized solution of these components design with accurate estimation of its optical performance. We are developing model of planetary signal detection through ray-tracing related beam propagation. Sun-like G-star with 695,500km in radius is light source that emitting rays towards a planet and an instrument model. Earth-like planet with 6,400km in radius is composed with atmosphere, land and ocean optical scattering model. The star and Earthlike planet is located 10 parsec away from hypothetic instrument model that has 6.5 meter diameter and F/20 telescope with spiders and Lyot coronagraph. Total 100,000,000 rays per spectral unit are emitted inside of the star surface and traced to directly instrument aperture or reflected and scattered through earth-like planetary model. The rays from emission to instrument aperture through star and planet model are traced by geometric optics condition. Then the rays passing through aperture in telescope model are traced with 8 additional para-basal rays that calculate beam propagation in order to wave optics properties. The model allows for simultaneous evaluations of the beam propagated imaging and radiometric performances for planetary signal detection with some cases of simulation. This simulation results would evaluate valuable information improving estimates space optical instrument in all phases of a space mission.

Initial look at the technology gap for direct imaging of exo-earths

Rhonda M. Morgan, Nicholas Siegler, Jet Propulsion Lab. (United States)

The NASA Astrophysics division intends to begin studies in 2016 of candidate flagship missions for proposal to the 2020 decadal survey. One of the anticipated candidates is an exo-earth direct imaging mission. The observation of an exo-earth requires a space telescope with 10e-10 suppression of the host star's light. While technologically challenging, the goal is not impossible. Many of the required technologies are TRL 1-3. After the successful on-orbit operation of WFIRST-AFTA, some of the technologies will be TRL 5-9. This paper summarizes the needed technologies and their development status in the context of current state of the art and expected maturity post-WFIRST-AFTA.

9605-1, Session 1

Requirements and design reference mission for the WFIRST-AFTA coronagraph instrument

Richard Demers, Frank G. Dekens, Robert J. Calvet, Zensheu Chang, Robert T. Effinger, Eric M. Ek, Laura Jones, Anthony Loc, Bijan Nemati, Martin Charley Noecker, Timothy Neville, Hung Pham, Hong Tang, Jet Propulsion Lab. (United States); Juan Villalvazo, Applied Sciences Lab. Inc. (United States)

The WFIRST-AFTA coronagraph instrument takes advantage of AFTAs 2.4-meter aperture to provide novel exoplanet imaging science at approximately the same cost as an Explorer mission. The AFTA coronagraph also matures direct imaging technologies to high TRL for an Exo-Earth Imager in the next decade. The coronagraph Design Reference Mission (DRM) optical design is based on the highly successful High Contrast Imaging Testbed (HCIT), with modifications to accommodate the AFTA telescope design, service-ability, volume constraints, and the addition of an Integral Field Spectrograph (IFS). In order to optimally satisfy the three science objectives of planet imaging, planet spectral characterization and dust debris imaging, the coronagraph is designed to operate in two different modes: Hybrid Lyot Coronagraph or Shaped Pupil Coronagraph. Active mechanisms change pupil masks, focal plane masks, Lyot masks, and bandpass filters to shift between modes. A single optical beam train can thus operate alternatively as two different coronagraphs.

Structural Thermal Optical Performance (STOP) analysis predicts the instrument contrast with the Low Order Wave Front Control loop closed. The STOP analysis was also used to verify that the optical/structural/thermal design provides the extreme stability required for planet characterization in the presence of thermal disturbances expected in a typical observing

scenario. This paper describes the instrument design and the flow down from science requirements to high level engineering requirements.

9605-2, Session 1

WFIRST/AFTA coronagraph technology development: component maturation and testbed validation

Ilya Poberezhskiy, Jet Propulsion Lab. (United States)

NASA's WFIRST/AFTA mission study includes the first high-contrast stellar coronagraph in space. This coronagraph will be capable of imaging and spectrally characterizing giant exoplanets similar to Neptune and Jupiter and possibly super-Earths, as well as circumstellar disks. The selected primary design called the Occulting Mask Coronagraph (OMC) combines two starlight suppression approaches, Shaped Pupil and Hybrid Lyot, in one instrument. The Phase-Induced Amplitude Apodization Complex Mask Coronagraph (PIAA-CMC) was selected as the backup design.

NASA set the objective of maturing the WFIRST/AFTA coronagraph to Technology Readiness Level (TRL) 5 by October 1, 2016, with 9 milestones to track the technology development progress along the way. Substantial advances have been made since the technology development plan was formulated in February of 2014, including successful fabrication of starlight suppression masks for all 3 selected coronagraph types and the testbed demonstration of better than 10^-8 contrast for the obscured AFTA pupil. We will present the milestone status and the recent technical results, including:

• Fabrication and characterization of coronagraph pupil plane and focal plane masks designed to work with the existing AFTA telescope.

• Experimental results demonstrating high contrast achieved on coronagraph testbeds in narrowband and broadband light.

• Status of the key coronagraph components and subsystems, including the deformable mirrors and the low-order wavefront sensing and control subsystem, which uses rejected starlight to sense and correct both the pointing jitter and low order wavefront aberrations. This subsystem will be integrated with the OMC coronagraph in 2015 for the next phase of starlight suppression experiments with dynamic input wavefront.

9605-3, Session 1

The WFIRST/AFTA coronagraph instrument optical design

Hong Tang, Jet Propulsion Lab. (United States)

The most recent concept for the Wide Field Infrared Survey Telescope (WFIRST) flight mission features an instrument that will perform exoplanet detection via coronagraphy of the host star. This observatory is based on the existing Astrophysics Focused Telescope Assets (AFTA) 2.4-meter telescope. The WFIRST/AFTA Coronagraph Instrument combines the Hybrid Lyot and Shaped Pupil Coronagraphs to meet the mission requirements. The optical layout Cycle 5 design fits the required enclosure and accommodates both coronagraphic techniques. We present the optical performances that include throughputs of the imaging channel and the IFS channel, the wavefront errors at the first pupil and the imaging channel, and polarization effects from optical coatings.

9605-4, Session 1

An overview of WFIRST/AFTA coronagraph optical modeling

John Krist, Gary Gutt, Jeffrey Jewell, Brian Kern, Bijan Nemati, David C. Palacios, Jet Propulsion Lab. (United States); A. J. Eldorado Riggs, Princeton Univ. (United States); Erkin Sidick, Hanying Zhou, Jet Propulsion Lab. (United States)

The WFIRST/AFTA 2.4 m space telescope currently under study includes a stellar coronagraph for the imaging and spectral characterization of extrasolar planets. Based largely on performance predictions from end-to-end optical propagation modeling, promising coronagraphic methods were selected in late 2013 for further consideration for use on AFTA. Since those downselect analyses further modeling work has been done on evaluating refined coronagraph designs, wavefront sensing and control, detector representation, and time-dependent effects. Thermal, structural, ray trace, and diffraction propagation models are used in these studies. Presented here is the progress to date and plans for future analyses.

9605-5, Session 1

Effect of DM actuator gain errors on the WFIRST/AFTA coronagraph contrast performance

Erkin Sidick, Fang Shi, Jet Propulsion Lab. (United States)

The WFIRST/AFTA 2.4 m space telescope currently under study includes a stellar coronagraph for the imaging and the spectral characterization of extrasolar planets. The coronagraph employs sequential deformable mirrors (DMs) to compensate for phase and amplitude errors in creating dark holes. DMs are critical elements in high contrast coronagraphs, requiring precision and stability measured in picometers to enable detection of Earth-like exoplanets. Working with the low-order wavefront-sensor (LOWFS) the DM that is conjugate to a pupil can also be used to correct low-order wavefront drift during a scientific observation. However, not all actuators in a DM have the same gain. When using such a DM in low-order wavefront sensing and control (LOWFSC), the actuator gain errors introduce high-spatial frequency error to the DM surface and thus worsen the contrast performance of the coronagraph. We have investigated the effect of actuator gain errors on the contrast performance of the coronagraph through modeling and simulations, and will present our results in this paper.

9605-6, Session 1

Wavefront correction with Kalman filtering for the WFIRST/AFTA coronagraph instrument

A. J. Eldorado Riggs, N. Jeremy Kasdin, Tyler D. Groff, Princeton Univ. (United States)

The only way to characterize most exoplanets spectrally is via direct imaging. For example, the Coronagraph Instrument (CGI) on the proposed Wide-Field Infrared Survey Telescope-Astrophysics Focused Telescope Assets (WFIRST/AFTA) mission plans to image and characterize several cool gas giants around nearby stars. The integration time on these faint exoplanets will be many hours to days. A crucial assumption for mission planning is that the time required to dig a dark hole (a region of high star-to-planet contrast) with deformable mirrors is small compared to science integration time. The science camera must be used as the wavefront sensor to avoid non-common path aberrations, but this approach can be quite time intensive. Several estimation images are required to build an estimate of the starlight electric field before it can be partially corrected, and this process is repeated iteratively until high contrast is reached. Here we compare simulated and experimental results of recursive wavefront estimation schemes. In particular, we test a Kalman filter and an extended Kalman filter (EKF) to reduce the total estimation exposure time and improve the robustness of the wavefront correction. We then put our results in the context of the WFIRST/AFTA CGI to predict the improved science yield from spending less time on wavefront correction. An EKF or other nonlinear filter also allows recursive, real-time estimation of sources incoherent with the star, such as exoplanets and disks, and may therefore reduce detection uncertainty.

9605-7, Session 2

Current best estimates of planet populations *(Invited Paper)*

Leslie A. Rogers, California Institute of Technology (United States)

Exoplanets are revolutionizing planetary science by enabling statistical studies of a large number of planets. Empirical measurements of planet occurrence rates inform our understanding of the ubiquity and efficiency of planet formation, while the identification of sub-populations and trends in the distribution of observed exoplanet properties provides insights into the formation and evolution processes that are sculpting distant Solar Systems. In this talk, I will review the current best estimates of planet populations. I will focus in particular on eta_Earth, the occurrence rate of habitable zone rocky planets, since this factor strongly influences the design of future space based exoplanet direct detection missions.

9605-8, Session 2

Low order wavefront sensing and control for WFIRST/AFTA coronagraph

Fang Shi, Kunjithapatham Balasubramanian, Randall D. Bartos, Randall C. Hein, Brian D. Kern, John Krist, Raymond K. Lam, James Moore, Keith Patterson, Joel F. Shields, Ilya Poberezhskiy, Erkin Sidick, Hong Tang, Tuan Truong, Brent Tweddle, J.Kent Wallace, Xu Wang, Jet Propulsion Lab. (United States)

NASA's WFIRST-AFTA Coronagraph will be capable of directly imaging and spectrally characterizing giant exoplanets similar to Neptune and Jupiter, and possibly even super-Earths, around nearby stars. To maintain the required coronagraph performance in a realistic space environment, a Low Order Wavefront Sensing and Control (LOWFS/C) subsystem is necessary. The LOWFS/C will use the rejected stellar light to sense and suppress the telescope pointing drift and jitter as well as low order wavefront errors due to the changes in thermal loading of the telescope and the rest of the observatory. The measured wavefront information will also be used for the coronagraph data post-processing (PSF subtraction) needed to further remove the speckle field and enhance the contrast. The WFIRST/AFTA LOWFS/C uses a Zernike phase contrast wavefront sensor with the phase shifting disk combined with the stellar light rejecting occulting mask, a key concept to minimize the non-common path error. Developed as a part of the Dynamic High Contrast Imaging Testbed (DHCIT), the LOWFS/C subsystem also consists of an Optical Telescope Assembly (OTA) Simulator to simulate the realistic wavefront error from WFIRST-AFTA telescope's jitter and thermal drift. The entire LOWFS/C subsystem will be integrated, calibrated, and tested in a dedicated LOWFS/C testbed before being integrated into DHCIT. In this paper we will present the LOWFS/C subsystem design, performance analysis, and LOWFS/C testbed integration and test (I&T) plan. We will also report the LOWFS/C testbed I&T status and some preliminary test results.

9605-9, Session 2

Shaped pupil Lyot coronagraph designs for WFIRST/AFTA

Neil T. Zimmerman, A. J. E. Riggs, N. Jeremy Kasdin, Princeton Univ. (United States); Alexis Carlotti, Institut de Planétologie et d'Astrophysique de Grenoble (France); Robert J. Vanderbei, Princeton Univ. (United States)

The exoplanet imaging campaign of WFIRST/AFTA will require a starlight suppression system surpassing 10^-8 contrast at angular separation 0.2 arcsec from the host star. The baseline instrument configuration includes several shaped pupil coronagraphs to meet these requirements across a range of observing modes. Our latest designs integrate the shaped pupil mask optimization with a Lyot architecture to yield deeper contrast and smaller inner working angle. By selecting distinct tradeoffs in contrast, working angle, azimuthal span, bandwidth, and throughput, we arrive at three mask configurations. Each one accommodates a major scientific goal: spectroscopic characterization, survey/imaging, and debris disk observations. Our Fourier propagation models incorporate wavefront control to predict the performance in the final image plane. We also analyze the sensitivity to low-order aberrations, alignment, and fabrication errors.

9605-10, Session 2

Laboratory performance of the shaped pupil coronagraphic architecture for the WFIRST/AFTA coronagraph

Eric Cady, Camilo A. Mejia Prada, Xin An, Kunjithapatham Balasubramanian, Rosemary T. Diaz, Jeffrey Jewell, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); N. Jeremy Kasdin, Princeton Univ. (United States); Brian D. Kern, Andreas Kuhnert, Bijan Nemati, Keith Patterson, Ilya Poberezhskiy, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); A. J. Eldorado Riggs, Princeton Univ. (United States); Daniel J. Ryan, Hanying Zhou, Robert P. Zimmer, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); Neil T. Zimmerman, Princeton Univ. (United States)

One of the two primary architectures being tested for the WFIRST/AFTA coronagraph instrument is the shaped pupil coronagraph, which uses a binary aperture in a pupil plane to create localized regions of high contrast in a subsequent focal plane. The aperture shapes are determined by optimization, and can be designed to work in the presence of secondary obscurations and spiders---an important consideration for coronagraphy with WFIRST/AFTA. We present the current performance of the shaped pupil testbed, including the results of AFTA Milestone 2, in which 6e-9 contrast was achieved in three independent runs starting from a neutral setting.

9605-11, Session 3

PIAACMC coronagraphic occulting mask fabrication, characterization, and modeling

Brian D. Kern, Daniel W. Wilson, Jet Propulsion Lab. (United States); Olivier Guyon, Subaru Telescope, National Astronomical Observatory of Japan (United States); Richard E. Muller, Kunjithapatham Balasubramanian, Erkin Sidick, Ilya Poberezhskiy, Jet Propulsion Lab. (United States); Ruslan Belikov, NASA Ames Research Ctr. (United States)

PIAACMC is a coronagraph architecture suited for high-contrast, small-IWA coronagraphy with high bandwidths (20%). The PIAACMC designs proposed for near-term implementation differ from PIAA architectures with testbed heritage in the inclusion of a phase-only occulting mask, allowing simpler (less aspheric) PIAA mirror shapes and smaller IWAs. The PIAACMC architecture also allows operation on obscured apertures, such as segmented and centrally-obstructed mirrors.

A high-performance PIAACMC mask design has been fabricated and measured at JPL's Micro Devices Lab. The design, measurements, and modeled performance are presented here, with particular attention to application on the WFIRST-AFTA coronagraph instrument. The conclusion is that the current fabrication capabilities at JPL's MDL are sufficient to deliver PIAACMC masks that would perform well in a planet characterization mission.

9605-12, Session 3

AFTA coronagraph performance: feedback from post-processing studies to overall design

Bertrand Mennesson, Jet Propulsion Lab. (United States)

The AFTA Coronagraph aims at forming direct images and measuring the first spectra of exoplanets in orbit around main sequence stars. An important aspect of the instrument is the ability to remove residual stellar speckles to improve the detectability of such planets. Based on detailed simulations and early laboratory tests, we present here some first estimates of the contrast gain expected from advanced post-processing treatments of AFTA-like coronagraphic images. We further discuss their impact on the overall design of the instrument, including its anticipated observing methodology.

9605-13, Session 3

The impact of radiation damage on photon counting with an EM-CCD for the WFIRST-AFTA coronagraph

Nathan L. Bush, David J. Hall, Andrew D. Holland, Ross Burgon, Neil J. Murray, Jason P. D. Gow, Matthew R. Soman, The Open Univ. (United Kingdom); Douglas Jordan, e2v technologies (UK) Ltd. (United Kingdom); Richard Demers, Leon K. Harding, Michael E. Hoenk, Darren Michaels, Bijan Nemati, Pavani Peddada, Jet Propulsion Lab. (United States)

The Wide Field Infra-Red Survey Telescope (WFIRST) is a NASA observatory designed to perform wide-field surveys of the near-infrared sky and direct imaging of exoplanets in the visible. Two instruments are on board. The Wide Field Instrument offers Hubble quality imaging over a 0.28 square degree field of view and will investigate the nature of Dark Energy and its relation to cosmological expansion. The second instrument is a high contrast coronagraph that will carry out the direct imaging and spectroscopic analysis of exoplanets, providing a means to probe the structure and composition of planetary systems.

Since the WFIRST coronagraph is expected to operate in low photon flux for long integration times, all noise sources must be kept to a minimum. In order to satisfy the coronagraph low noise requirements, the Electron Multiplication (EM)-CCD has been baselined for both the imaging and spectrograph cameras. The EM-CCD was selected in comparison with other candidates because of its low effective electronic read noise at sub-electron values with appropriate multiplication gain setting. The presence of other noise sources, however, such as thermal dark signal and Clock Induced Charge (CIC), need to be characterized and mitigated. In addition, operation within a space environment will subject the device to radiation damage that will degrade the Charge Transfer efficiency (CTE) of the device throughout the mission lifetime.

Here we present our latest results from pre-and post- irradiation test of the e2v CCD201-20 BI EM-CCD sensor, baselined for the WFIRST-AFTA coronagraph instrument.

9605-14, Session 3

Electron multiplication CCD detector technology advancement for the WFIRST-AFTA coronagraph integral field spectrograph

Leon K. Harding, Michael Cherng, Richard Demers, Michael E. Hoenk, Darren Michaels, Bijan Nemati, Pavani Peddada, Jet Propulsion Lab. (United States)

The WFIRST-AFTA mission is a 2.4 meter-class space telescope that will be used across a swath of astrophysical research domains, including dark energy, extrasolar planet exploration and galactic/extragalactic surveys. The observatory will host two major astronomical instruments: a short wave infrared Wide Field Instrument (WFI) provided by GSFC and a High Contrast Imaging Coronagraph provided by JPL. The Coronagraph will include an Integral Field Spectrograph (IFS), capable of spectral characterization of exoplanets. The expected science photon flux on the IFS sensor is extremely low given that the exoplanet targets will reflect light of intensity 109 lower than that of the parent star. Furthermore, in the IFS, light from the target point spread function will be spread over multiple sensor pixels for spectral dispersion. In order to achieve the extremely low noise performance required to detect planets under such low flux conditions, the Electron Multiplication CCD (EMCCD) has been baselined for both of the Coronagraph's sensors; the imaging camera and IFS. EMCCDs have the capability of amplifying signal at the single photon level via avalanche multiplication in the EM register – an additional stage after the conventional CCD register. JPL has established an EMCCD test laboratory in order to advance EMCCD maturity to TRL-6. This plan includes full sensor characterization with the WFIRST life-span and space environment in mind. Test parameters include read noise, dark current, and clock induced charge. In addition, by considering the unique challenges of the space environment, JPL will assess degradation to the sensor's charge transfer efficiency, as a result of damage from high energy particles such as protons, electrons and cosmic rays. Under JPL's guidance, science-grade CCD201-20 EMCCD sensors have been irradiated to a proton fluence that reflect the projected WFIRST orbit. Performance degradation due to radiation displacement damage is reported. In addition, the results of techniques intended to mitigate radiation-induced electron trapping such as charge injection, thermal cycling and clocking patterns are discussed.

9605-15, Session 3

Prototype imaging spectrograph for coronagraphic exoplanet studies (PISCES) for WFIRST/AFTA

Qian Gong, Michael Mcelwain, Bradford Greeley, Bryan Grammer, Catherine Marx, Nargess Memarsadeghi, George Hilton, NASA Goddard Space Flight Ctr. (United States); Marshall Perrin, Space Telescope Science Institute (United States); Jorge Domingo Llop Sayson, Karl Stapelfeldt, NASA Goddard Space Flight Ctr. (United States); Richard Demers, Hong Tang, Brian Kern, Janan Ferdosi, Jet Propulsion Lab. (United States)

PISCES is a prototype lenslet array based integral field spectrograph (IFS) designed for high contrast imaging of extrasolar planets. PISCES will be used to advance the technology readiness of the high contrast IFS baselined on the WFIRST/AFTA Coronagraph Instrument. PISCES will be integrated into the high contrast imaging testbed (HCIT) at the Jet Propulsion Laboratory and will work with both the Hybrid Lyot Coronagraph (HLC) and the Shaped Pupil Coronagraph (SPC). We will present the PISCES optical design, including the similarities and differences of lenslet based IFSs to normal spectrometers, the trade-off between a refractive design and reflective design, as well as the compatibility to upgrade from the current 1k x 1k detector array to 4k x 4k detector array. The optical analysis, alignment plan, and mechanical design of the instrument will be addressed.

9605-16, Session 4

Studies of the effects of control bandwidth and dark-hole size on the HCIT contrast performance

Erkin Sidick, Stuart B. Shaklan, Kunjithapatham

Balasubramanian, Eric Cady, Jet Propulsion Lab. (United States)

We have carried out both theoretical and experimental studies of the sensitivity of dark hole contrast to the control bandwidth and dark-hole dimensions in high-contrast broadband stellar coronagraphy. We have evaluated the performance of DM actuator solutions in the presence of occulting mask defects using one to five 2%-wide bands spanning a 10% bandpasss. We have also investigated the dependence of the HCIT contrast performance on the size of dark-hole area including large dark holes formed at the Nyquist limit of the DM.

9605-17, Session 4

High-contrast imager for complex aperture telescopes (HiCAT): 3. First laboratory results including wavefront control

Mamadou N'Diaye, Élodie Choquet, Johan Mazoyer, Space Telescope Science Institute (United States); Alexis Carlotti, Institut de Planétologie et d'Astrophysique de Grenoble (France); Laurent A. Pueyo, Space Telescope Science Institute (United States); Sylvain Egron, Lucie Leboulleux, Olivier Levecq, Institut d'Optique Graduate School (France); Marshall D. Perrin, Space Telescope Science Institute (United States); J.Kent Wallace, Jet Propulsion Lab. (United States); Chris A. Long, Rachel Lajoie, Charles-Philippe Lajoie, Space Telescope Science Institute (United States); A. J. Eldorado Riggs, Neil T. Zimmerman, Robert J. Vanderbei, Tyler D. Groff, N. Jeremy Kasdin, Princeton Univ. (United States); Dimitri Mawet, California Institute of Technology (United States); Bruce A. Macintosh, Stanford Univ. (United States); Stuart B. Shaklan, Jet Propulsion Lab. (United States); Rémi Soummer, Space Telescope Science Institute (United States)

HiCAT is a high-contrast imaging testbed designed to provide complete solutions in wavefront sensing, control and starlight suppression with complex aperture telescopes. The pupil geometry of such observatories includes primary mirror segmentation, central obstruction, and spider vanes, which make direct imaging of habitable worlds very challenging. The testbed alignment was completed in the summer of 2014, exceeding specifications with a total wavefront error of 12nm rms over a 18mm pupil. The installation of two deformable mirrors for wavefront control is to be completed in the winter of 2015. In this communication, we report on the first testbed results using a classical Lyot coronagraph. We also present the coronagraph design for HiCAT geometry, based on our recent development of Apodized Pupil Lyot Coronagraph (APLC) with shaped-pupil type optimizations. These new APLC-type solutions using two-dimensional shaped-pupil apodizer render the system quasi-insensitive to jitter and low-order aberrations, while improving the performance in terms of inner working angle, bandpass and contrast over a classical APLC.

9605-18, Session 4

EXCEDE technology development III: demonstration of polychromatic contrast in vacuum at 1.2 L/D

Dan Sirbu, Sandrine J. Thomas, Ruslan Belikov, NASA Ames Research Ctr. (United States); Julien Lozi, National Astronomical Observatory of Japan (United States); Eduardo A. Bendek, Eugene A. Pluzhnik, Dana Lynch, NASA Ames Research Ctr. (United States); Troy T. Hix, Lockheed Martin Space Systems Co. (United States); Peter T. Zell, NASA Ames Research Ctr. (United States); Glenn H. Schneider, The Univ. of Arizona (United States); Olivier Guyon, National Astronomical Observatory of Japan (United States)

Exoplanetary Circumstellar Environments and Disk Explorer (EXCEDE) is a proposed Explorer-class NASA space mission. It uses a 0.7-m diameter telescope with a Phase Induced Amplitude Apodization (PIAA) Coronograph and a Deformable Mirror (DM) to create a "dark-hole" or a region of high-contrast starlight suppression at the focal plane to allow direct imaging of debris disks and exoplanets. EXCEDE will also serve as a technological and scientific precursor for an exo-Earth imaging mission. The PIAA coronagraph allows for an aggressive inner working angle of 1.2 l/D for imaging in the habitable zone with high throughput. We have been developing the EXCEDE starlight suppression system technology for high-contrast imaging capability in polychromatic light in vacuum at the Lockheed Martin Advanced Technology Center. In this paper, we present the latest of these results, including high contrast demonstrations in vacuum at inner working angles of 1.2 l/D.

9605-19, Session 4

Broadband results with the visible nulling coronagraph

Brian A. Hicks, Richard G. Lyon, NASA Goddard Space Flight Ctr. (United States); Peter Petrone III, Sigma Space Corp. (United States); Ian J. Miller, LightMachinery Inc. (Canada); Matthew R. Bolcar, Mark Clampin, NASA Goddard Space Flight Ctr. (United States); Michael A. Helmbrecht, Iris AO, Inc. (United States); Udayan Mallik, NASA Goddard Space Flight Ctr. (United States)

The key to broadband operation of the Visible Nulling Coronagraph (VNC) is introducing an achromatic field inversion between interfering beams. Here we present broadband results using Fresnel rhombs in each arm as orthogonally aligned half wave phase retarders, the goal being a demonstration of 1x10^-9 at 2 lambda/D over a 40 nm bandpass centered at 633 nm. In practice, the challenge with this approach is meeting arcsecond level fabrication and alignment requirements between rhombs in a pair and between pairs relative to the instrument, as well as the sub-arcminute requirement on orthogonality between pairs. A multi-step approach to alignment using coarse positioners for each rhomb and each rhomb pair is used to get within range of piezos used for fine positioning. Adapting the narrowband sensing and control approach to include positioning of the piezo-mounted rhombs is described.

9605-20, Session 4

Fabrication and characterization of exoplanet coronagraph shaped pupil masks and laboratory scale star-shade masks

Kunjithapatham Balasubramanian, Victor E. White, Karl Y. Yee, Pierre M. Echternach, Richard Muller, Matthew R. Dickie, Eric Cady, Daniel J. Ryan, Jet Propulsion Lab. (United States); A. J. Eldorado Riggs, Neil T. Zimmerman, N. Jeremy Kasdin, Princeton Univ. (United States)

NASA WFIRST/AFTA mission proposes to include a coronagraph to find and characterize earth like exoplanets. Masks are needed to suppress the host star light to about 10-10 level contrast over a broad bandwidth to enable the coronagraph mission objectives. Such masks for high contrast internal as well as external coronagraphic imaging require various fabrication technologies to meet a wide range of specifications, including precise shapes, micron scale island features, ultra-low reflectivity regions,

uniformity, wave front quality, etc. We present the approaches employed at JPL to produce pupil plane and image plane coronagraph masks, and lab-scale external occulter masks by combining electron beam, ion beam, deep reactive ion etching, and black silicon technologies with illustrative examples of each, highlighting accomplishments from the high contrast imaging testbed (HCIL) at JPL and from the high contrast imaging lab (HCIL) at Princeton University.

9605-21, Session 5

Active correction of aperture discontinuities for high contrast imaging: parametrical analysis

Johan Mazoyer, Laurent A. Pueyo, Space Telescope Science Institute (United States); Colin A. Norman, Johns Hopkins Univ. (United States); Marshall D. Perrin, Rémi Soummer, Mamadou N'Diaye, Élodie Choquet, Space Telescope Science Institute (United States); Alexis Carlotti, Institut de Planétologie et d'Astrophysique de Grenoble (France); Dimitri Mawet, European Southern Observatory (Chile)

As the performance of coronagraphs improves, the achievable contrast is more and more dependent of the shape of the pupil. The future generation of space and ground based coronagraphic instruments will have to achieve high contrast levels on on-axis and/or segmented telescopes. To correct for the high amplitude aberrations introduced by secondary mirror structures and segmentations of the primary mirror, we explore a two deformable mirror (DM) method. The major difficulty of several DM methods is the non-linear relation linking actuator strokes to the point spread function in the coronagraph focal plane. The Active Compensation of Aperture Discontinuities (ACAD) method is achieving this minimization by solving a non linear differential Monge Ampere equation. Once this open loop method have reached the minimum, a close-loop stroke minimization method can be applied to correct for phase and amplitude aberrations to achieve the ultimate contrast. In this paper we will first describe the recent developments in the end to end propagation simulations of the two DM correction. These propagation simulations will be then use to explore the performance of the ACAD + stroke minimization method for apertures varying on a large space of parameters (width and number of secondary support structures, size of the secondary mirror, number of missing segments, ...). Finally, we will test this method on several known space telescope apertures (JWST, WFIRST, ATLAST).

9605-22, Session 5

Managing the optical wavefront for exoplanet imaging with a space coronagraph

John T. Trauger, Dwight C. Moody, John Krist, Jet Propulsion Lab. (United States)

We update the designs, demonstrations, and science prospects for the direct imaging and spectroscopic characterization of exoplanetary systems with the hybrid Lyot coronagraph. We update our model predictions for exoplanet science performance with the flagship AFTA/WFIRST mission as well as dedicated smaller-class space observatories. Together with a pair of deformable mirrors for optical wavefront control, the hybrid Lyot coronagraph creates high contrast dark fields of view extending to within angular separations of 2.5 lambda/D from the central star at visible wavelengths. Performance metrics and design trades are presented, including image contrast, spectral bandwidth, overall efficiency and throughput, and model-validating laboratory demonstrations.

9605-23, Session 5

Estimation of chromatic errors from broadband images for high contrast imaging

Dan Sirbu, Ruslan Belikov, NASA Ames Research Ctr. (United States)

Usage of an internal coronagraph with an adaptive optical system for wavefront correction for direct imaging of exoplanets is currently being considered as an instrument addition to the AFTA mission to follow the James Web Space Telescope, and many other mission concepts. The main technical challenge associated with direct imaging of exoplanets is to effectively control both the diffraction and scattered light from the star so that the dim planetary companion can be seen. For the deformable mirror (DM) to recover a dark hole region with sufficiently high contrast in the image plane, wavefront errors are usually estimated using probes on the DM. To date, most broadband lab demonstrations use narrowband filters to estimate the chromaticity of the wavefront error, but this reduces the photon flux per filter and requires a filter system. Here, we propose a method to estimate the chromaticity of wavefront errors using only a broadband image. This is achieved by using special DM probes that have sufficient chromatic diversity. We also examine and quantify the integration time performance gains that can be obtained by using such chromatic probes in broadband light to directly estimate the electric field.

9605-24, Session 5

Preliminary analysis of effect of random segment errors on coronagraph performance

Mark T. Stahl, H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States); Stuart B. Shaklan, Jet Propulsion Lab. (United States)

Comparative exo-Earth planetology requires the ability to characterize dozens of planets. Based on current design reference missions, a telescope with an aperture as large as 12 to 16 meters may be required. Obviously such a telescope will need to be segmented. But, temporal rigid-body motion of individual segments can result in leakage which reduces contrast. To fully characterize exo-Earths requires contrast stability of 10^-11. This paper reports a preliminary investigation of the sensitivity of contrast stability to segment rigid-body motion stability.

9605-25, Session 5

Linearized dark field control (LDFC) and self-calibration for high contrast imaging

Olivier Guyon, Johanan L. Codona, The Univ. of Arizona (United States); Brian D. Kern, Jet Propulsion Lab. (United States); Ruslan Belikov, NASA Ames Research Ctr. (United States)

High contrast imaging systems aimed at detecting and characterizing exoplanets must reach deep contrast levels over part of the focal plane image. This is achieved by iteratively cancelling diffracted starlight in a pre-defined region, in which exoplanets can be imaged and characterized. Each iteration requires several images, each with a different deformable mirror shape (probes), to be acquired in order to solve for the complex amplitude field (dark field) in the dark region. This approach is slow (several images need to be acquired, each with sufficiently long exposure to measure speckles), disruptive (the optimal dark field solution must be periodically broken to measure speckles) and prone to errors due to imperfect knowledge of the DM-to-speckles relationship.

We present two techniques that significantly improve on the conventional

approach described above:

- We show that a model-free self-calibration of the system response matrix can be performed by moving small groups of actuators sequentially and using a non-linear solver.

- We show that the dark field complex amplitude is linearly coupled with brighter speckles lying outside the geometric control region, and with speckles outside the control spectral band. It is therefore possible to control dark field speckles with a fast model-free linear controller using brighter starlight. By utilizing light outside the dark hole (both spatially and spectrally), the control loop is significantly simpler, faster, and more sensitive. It also does not require a model of the system, as the linear relationship can be easily and quickly measured. This approach enables full utilization of the available observing time for science observations, and is more robust to non-ideal deformable mirror behaviours, such as hysteresis.

The Linearized Dark Field Control (LDFC) is also a powerful aid to PSF calibration, as the residual dark field speckles can be inferred from the intensity of the brighter speckles used as the input to the LDFC loop.

9605-26, Session 5

Blind source separation approaches for exoplanet signal extraction

Dmitry Savransky, Cornell Univ. (United States)

While the next generation of exoplanet direct-imaging instrumentation that is currently coming online is making remarkable strides in increasing achievable contrast levels, post-processing still plays a crucial role in the detection of exoplanets. The current state of the art involves extracting the planet signal from the noisy background using a variety of techniques, several of which (including all variations on principal component analysis) belong to a general class of algorithms called Blind Source Separation (BSS). Here we demonstrate the application of other BSS algorithms that have previously not been tested on exoplanet imaging data, including independent component analysis, common spatial pattern filtering, and stationary subspace analysis. We utilize both synthetic and real imaging data and discuss the strengths and weaknesses of each approach (as well as available degrees of freedom in their implementation) as a function of the correlation and relative magnitude of various noise sources commonly found in exoplanet imaging data.

9605-27, Session 5

Point spread function subtraction methods for high-contrast imaging in the context of future space-based coronagraph instruments

Marie Ygouf, Rémi Soummer, Marshall D. Perrin, Laurent A. Pueyo, Space Telescope Science Institute (United States); Bruce A. Macintosh, Stanford Univ. (United States)

Direct detection and characterization of Earth-like exoplanets with contrasts of 10^-9 require space-based instruments optimized for high-contrast imaging. In this context, the Wide-Field Infrared Survey Telescope - Astrophysics Focused Telescope Assets (WFIRST-AFTA) project will reach contrasts of about 10^-8, using state-of-the-art starlight suppression and wavefront control techniques. A ten-fold contrast improvement to reach the required contrast of 10^-9 is expected to come from post-processing techniques. But the methods of point spread function (PSF) subtraction currently used on both ground-based and space-based instruments have not yet been demonstrated at such high contrast level.

In this communication, we explore new ways of implementing post-processing methods on AFTA-like simulated images, taking into account the presence of deformable mirrors, coronagraph and an IFS. Among all the existing PSF subtraction techniques, the Karunhen-Loève Image Projection (KLIP) algorithm is one of the most promising for the future space-based coronagraphic instruments. This method has been applied successfully on real ground-based and space-based images with a contrast up to 10^-6. But its performances have to be demonstrated at the high contrast level of WFIRST-AFTA. In this communication, we perform a sensitivity analysis of KLIP on AFTA-like simulated images and we assess the preliminary performance of the algorithm in terms of contrast.

9605-28, Session 6

Exo-C: a probe-scale space observatory for direct imaging and spectroscopy of extrasolar planetary systems *(Invited Paper)*

Karl Stapelfeldt, NASA Goddard Space Flight Ctr. (United States); Frank G. Dekens, Michael P. Brenner, Keith R. Warfield, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); Ruslan Belikov, NASA Ames Research Ctr. (United States); Paul B. Brugarolas, Geoffrey Bryden, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); Kerri L. Cahoy, Massachusetts Institute of Technology (United States); Supriya Chakrabarti, Univ. of Massachusetts Lowell (United States); Serge Dubovitsky, Robert T. Effinger, Casey Heeg, Brian Hirsch, Andrew Kissil, John Krist, Jared J. Lang, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); Mark S. Marley, NASA Ames Research Ctr. (United States); Michael McElwain, NASA Goddard Space Flight Ctr. (United States); Victoria Meadows, Univ. of Washington (United States); Joel A. Nissen, Jeffrey M. Oseas, Christopher Pong, Eugene Serabyn, Eric T. Sunada, John T. Trauger, Jet Propulsion Lab. (United States) and California Institute of Technology (United States)

"Exo-C" is NASA's first community study of a modest aperture space telescope optimized for high contrast observations of exoplanetary systems. The mission will be capable of taking optical spectra of nearby exoplanets in reflected light, discovering previously undetected planets, and imaging structure in a large sample of circumstellar disks. It will obtain unique science results on planets down to super-Earth sizes and serve as a technology pathfinder toward an eventual flagship-class mission to find and characterize habitable Earth-like exoplanets. We present the mission/payload design and its science yield, highlighting steps to reduce mission cost/risk relative to previous mission concepts. Key elements are an 1.4 m unobscured telescope aperture, an internal coronagraph with deformable mirrors for precise wavefront control, and an orbit and observatory design chosen for high thermal stability. Exo-C has a similar telescope aperture, orbit, lifetime, and spacecraft bus requirements to the highly successful Kepler mission (which is our cost reference). The needed technology development is on-course to support a mission start in 2017, should NASA decide to proceed. This paper summarizes the study final report completed in February 2015. Key accomplishments include excellent modeled telescope stability, a telescope and instrument design that is optimal for dual polarization throughput, and fitting the mission into the prescibed cost cap.

9605-29, Session 6

Ultra-stable thermal-optical performance from the Exo-C design study

Joel A. Nissen, Robert T. Effinger, Andrew Kissil, Jet Propulsion Lab. (United States)

Space-based coronagraphs offer the promise of direct observations of exoplanets, ultimately within the habitable zone of many stars. In order to take full advantage of the 10-9 contrast achievable at the inner working

angle, the observatory will require unprecedented wavefront stability. For reasons of observing efficiency and in order to pull a dim planet from the coronagraph speckle, it is also highly desirable that the wavefront is stable at the picometer level during observing maneuvers. Exo-C is a design study for a space-based internal coronagraph with a 1.4 meter unobscured aperture that achieves this goal maintaining contrast drift below 10-10. To achieve this stability, a systems level approach is necessary, starting with the choice of a Kepler-like Earth trailing orbit. In this orbit, the only thermal disturbances are the Sun and the power dissipation inside the spacecraft. To take full advantage of the stable environment of the earth trailing orbit, the sunshade fully covers the Exo-C optical barrel on the Sun-facing side and is flat so that when the spacecraft is rolled around the optical axis, from +15° to -15°, the solar load on the optical barrel is unchanged. A combination of low CTE materials and 29 thermal control zones on the optical barrel ensures that the primary-secondary mirror spacing drifts are under a nanometer. Thermal disturbances resulting from heat dissipation in the spacecraft bus are managed with passive and active thermal control of the interface. This paper details the modeling and design strategies that result in an ultra-stable coronagraph.

9605-30, Session 6

PIAA coronagraph design for the Exo-C Mission concept

Ruslan Belikov, NASA Ames Research Ctr. (United States); John Krist, Jet Propulsion Lab. (United States); Karl Stapelfeldt, NASA Goddard Space Flight Ctr. (United States)

The Exoplanet Coronagraph (Exo-C) mission concept consists of a 1.4m space telescope equipped with a high performance coronagraph to directly image exoplanets and disks around many nearby stars. One of the coronagraphs under consideration to be used for this mission is the highly efficient Phase-Induced Amplitude Apodization (PIAA) coronagraph. This paper presents and describes: (a) the PIAA design for Exo-C; (b) an end-to-end performance analysis including sensitivity to jitter, and (c) the expected science yield of Exo-C with PIAA. The design is a "classic" PIAA, which is made possible by the unobstructed aperture. It consists of a pair of forward and inverse PIAA optics and a simple hard-edge focal plane mask. A mild binary pre-apodizer relaxes the radius of curvature on the PIAA mirrors to be easier than typical PIAA mirrors manufactured to date. This design has been optimized for high performance while being relatively insensitive to low order aberrations. The throughput is 90% relative to telescope PSF, while the inner working angle is 2.1 l/D and the contrast is ~1e-9 in a full 360-degree field of view (after wavefront control with two DMs), all for a 20% spectral band centered around 550nm. The design also has good tolerance to jitter: contrast at 1.6mas jitter is still within a factor of a few of 1e-9.

9605-31, Session 7

The Exo-S Probe Class Starshade Mission *(Invited Paper)*

Sara Seager, Massachusetts Institute of Technology (United States); Margaret C. Turnbull, Global Science Institute (United States); William B. Sparks, Space Telescope Science Institute (United States); Mark Thomson, Stuart B. Shaklan, Jet Propulsion Lab. (United States); Aki Roberge, Marc J. Kuchner, NASA Goddard Space Flight Ctr. (United States); N. Jeremy Kasdin, Princeton Univ. (United States); Shawn Domagal-Goldman, NASA Goddard Space Flight Ctr. (United States); Webster Cash, Univ. of Colorado at Boulder (United States); Keith R. Warfield, Douglas Lisman, Daniel P. Scharf, David R. Webb, Rachel Trabert, Stefan R. Martin, Eric Cady, Cate Heneghan, Jet Propulsion Lab. (United States)

Exo-S is a direct imaging space-based mission to discover and characterize exoplanets. With its modest size, Exo-S bridges the gap between census missions like Kepler and a future space-based flagship direct imaging exoplanet mission. With the ability to reach down to Earth-size planets in the habitable zones of nearly two dozen nearby stars, Exo-S is a powerful first step in the search for and identification of Earth-like planets. Compelling science can be returned at the same time as the technological and scientific framework is developed for a larger flagship mission.

The Exo-S Science and Technology Definition Team studied two viable and compelling starshade-telescope missions for exoplanet direct imaging, targeted to the $1B cost guideline. The first Exo-S mission concept is a starshade and telescope system dedicated to each other for the sole purpose of direct imaging for exoplanets (The "Starshade Dedicated Mission"). The starshade and commercial, 1.1-m diameter telescope co-launch, sharing the same low-cost launch vehicle, conserving cost. The Dedicated mission orbits in a heliocentric, Earth leading, Earth-drift away orbit. The telescope has a conventional instrument package that includes the planet camera, a basic spectrometer, and a guide camera.

The second Exo-S mission concept is a starshade that launches separately to rendezvous with an existing on orbit space telescope (the "Starshade Rendezvous Mission"). The existing telescope adopted for the study is the WFIRST-AFTA (Wide-Field Infrared Survey Telescope Astrophysics Focused Telescope Asset). The WFIRST-AFTA 2.4-m telescope is assumed to have previously launched to a Halo orbit about the Earth-Sun L2 point, away from the gravity gradient of Earth orbit which is unsuitable for formation flying of the starshade and telescope. The impact on WFIRST/AFTA for starshade readiness is minimized; the existing coronagraph instrument performs as the starshade science instrument, formation guidance is handled by the existing coronagraph focal planes with minimal modification, and an added transceiver.

9605-32, Session 7

Optical instrumentation for science and formation flying with a starshade observatory

Stefan R. Martin, Eric Cady, Stuart B. Shaklan, Daniel P. Scharf, Hong Tang, Jet Propulsion Lab. (United States)

In conjunction with a space telescope of modest size, a starshade enables observation of small exoplanets close to the parent star by blocking the direct starlight while the planet light remains unobscured. The starshade will be flown some tens of thousands of kilometers ahead of the telescope and maintained in the direct line of sight to the star to an accuracy of a meter or so. Using the optical telescope as part of the sensor, we show how this alignment can be maintained by observing out of band starlight that leaks around the starshade. Science instruments may include a wide field camera for imaging the target exoplanetary system as well as an integral field spectrometer for characterization of exoplanets. We discuss the preliminary designs of the optical instruments for observatories such as Exo-S and a starshade-ready WFIRST/AFTA and show how a compact, standalone instrument package could be developed as an add-on to future space telescopes. We discuss observation times for exoplanets, formation flying and control, retargeting maneuvers and other aspects of the mission.

This work was conducted at the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration.

9605-33, Session 7

Design reference missions for the Exoplanet Starshade (Exo-S) Probe-Class study

Rachel Trabert, Stuart B. Shaklan, Douglas Lisman, Jet Propulsion Lab. (United States); Aki Roberge, NASA

Goddard Space Flight Ctr. (United States); Margaret C. Turnbull, Global Science Institute (United States); Shawn Domagal-Goldman, Christopher C. Stark, NASA Goddard Space Flight Ctr. (United States)

Exo-S is a direct imaging space-based mission to discover and characterize exoplanets. The mission is comprised of two formation-flying spacecraft – a starlight suppressing starshade and a telescope separated by ~30,000 km. To align the starshade between the target star and telescope, one of the two spacecraft must perform a retargeting slew. This drives the need for a sophisticated program to help optimize this path to maximize target yield within mission constraints such as solar and earth avoidance angles, thrust and fuel limitations, and target scheduling for previously-discovered known giant planets. The Design Reference Mission (DRM) describes the sequence of observations to be performed and estimates the number of planets that will be detected and characterized. It is executed with a Matlab-based tool developed for the Exo-S Study. Here we show analyze three case studies:

• Case 1: Starshade with a 1.1m dedicated telescope focused on searching for earths in the Habitable Zone (HZ).

• Case 2: Starshade with a 1.1m dedicated telescope focused on maximizing planet harvest return and characterization.

• Case 3: Starshade that rendezvous with a 2.4 m shared telescope focused on searching for earths in the HZ.

Previous starshade DRM tools have been reported in the literature, all of them focused on detection and/or characterization of Earth-twins in the habitable zone. This study has taken then next step and focused on total planet harvest including known Gas Giants, Earths in the Habitable Zone and elsewhere, super-earths, sub-Neptunes, and Jupiters. The DRM employs a hierarchical approach: an observation schedule of known radial velocity gas giants, whose availabilities for observation are known form their orbital parameters, forms a "framework" of observation that have a high probability of success. Between these observations, the next highest priority stars are scheduled and these in turn form the framework for the next observational tier. We report the expected observational completeness, planet yields, and planet characterizations for the three case studies.

9605-34, Session 7

Error budgets for the Exoplanet Starshade (Exo-S) Probe-Class Mission study

Stuart B. Shaklan, Luis Marchen, Eric Cady, Douglas Lisman, Stefan R. Martin, Mark Thomson, Jet Propulsion Lab. (United States)

Exo-S is a probe-class mission study that includes the Dedicated mission, a 30 m starshade co-launched with a 1.1 m commercial telescope in an Earth-leading deep-space orbit, and the Rendezvous mission, a 34 m starshade indended two work with a 2.4 m telescope in an Earth-Sun L2 orbit. This paper presents error budgets for the detection of Earth-like planets with each of these missions. The budgets include manufacture and deployment tolerances, the allowed thermal fluctuations and dynamic motions, formation flying alignment requirements, surface and edge reflectivity requirements, and the allowed transmission due to micrometeoroid damage. The budget is created through electric field propagation modeling of a variety of perturbations to the starshade design under consideration.

9605-35, Session 7

The Exo-S Starshade mechanical design

Mark Thomson, David R. Webb, Brian Hirsch, Brian P. Trease, Vinh M. Bach, Brian Y. Lim, Jet Propulsion Lab. (United States)

The mechanical and structural design of a 34-meter diameter deployable externally occulting starshade for the Exoplanet Rendezvous Mission (ERM) described in the Exo-S Final Report is detailed. This starshade is being developed at JPL with funding from NASA SMD Astrophysics under the TDEMs and Exoplanet Program Office.

The JPL starshade has grown in an environment of mechanical engineering prototype development in collaboration with optical, and systems engineers. This collaboration has yielded realistically achievable requirements, designs and hardware that will provide deployment and maintenance of the shape and stability needed for suppression of visible starlight to at least 10E-10 with inner working angles sufficient to image Earth-like exoplanets in the habitable zone using a 2.86-meter conventional telescope, or smaller.

Various aspects of the JPL starshade design will be presented including how the structural architecture supports the optical design with adequate in-plane precision and stability. Mechanical design heritage, the deployment sequence and petal, inner disk structure, perimeter truss ring structure, spoke, hub, petal and inner disc optical shield designs will be outlined.

9605-37, Session 8

Fully achromatic nulling interferometer (FANI) for high SNR exoplanet characterization

François B. Hénault, Institut de Planétologie et d'Astrophysique de Grenoble (France)

Space-borne nulling interferometers have long been considered as the best option for characterizing extra-solar planets. Solutions for achieving deep starlight extinction are now numerous and well demonstrated. However they essentially aim at realizing an achromatic central null. In this communication is described a major improvement of the technique, where the achromatization process is extended to the entire fringe pattern. The basic principle of this Fully achromatic nulling interferometer consists in inserting dispersive elements along the arms of the interferometer. Herein this principle is explained and illustrated by a preliminary optical design.

9605-38, Session 8

A 4-telescope linear nuller based on an integrated optics beam combiner

Ronny Errmann, Romina Diener, Stefano Minardi, Friedrich-Schiller-Univ. Jena (Germany); Lucas Labadie, Univ. zu Köln (Germany); Felix Dreisow, Stefan Nolte, Thomas Pertsch, Matthias Heinrich, Friedrich-Schiller-Univ. Jena (Germany)

Nulling interferometry is a coronographic technique particularly powerful at long infrared wavelengths (~3-10 microns) where it combines efficient starlight suppression and high angular resolution to resolve and characterize spectroscopically the thermal emission of exoplanets orbiting a nearby Sun like star. This technique has been technically explored in details during the last decade in the context of space projects such as Darwin, TPF or FKSI. While nulling interferometry in space is still hampered by high costs and by the lack of technological maturity of some sub-systems, ground-based nulling with the LBTI and Keck has shown the power of the technique to study the circumstellar environment of nearby solar-type stars.

An important aspect to minimize residual stellar leaks being transmitted by the interferometer is to combine the beams of more than two or three telescopes in order to broaden the central null. Several configurations have been proposed on paper to reach a broader dark fringe. To verify the experimental validity of these options, we have conducted a specific laboratory study of the so-called Angel's scheme (Angel & Wolf 1997) that foresees the combination of four telescopes to produce a null with a theta^6 shape. The novelty is in the use of an integrated optics beam combiner to implement a cascaded 4-telescope nulling scheme able to significantly broaden the central null. We report on the properties of the beam combiner, on the polynomial dependance of the produced null, and on the promising characterization results obtained at visible wavelengths. We also draw new perspectives to extend this approach to the mid-infrared in the context of our ALSI project, which aims at delivering optimized IO combiners for the 3-10 microns range.

9605-39, Session 8

A pareto-optimal characterization of small-scale distributed occulter/telescope systems

Adam W. Koenig, Simone D'Amico, Bruce A. Macintosh, Stanford Univ. (United States)

Distributed occulter/telescope systems are a promising candidate to enable direct imaging of exoplanets. However, proposed missions using this concept such as NASA's New Worlds Observer are exceptionally large with occulter diameters of tens of meters and inter-spacecraft separations of tens of megameters, requiring deployment in deep space. The costs associated with these concepts are estimated to be in the billions of dollars. In this work, we assess the feasibility of shrinking the occulter and telescope to a size compatible with microsatellites or nanosatellites and reducing the spacecraft separation by several orders of magnitude in order to allow deployment in Earth orbit, drastically reducing mission costs. We will use the convex optimization formulation introduced by previous authors with an improved objective function and an additional shadow recovery constraint to generate a pareto-optimal relationship between the performance specifications of the system (angular resolution, shadow size, shadow depth, shadow bandwidth, etc.) in the microsatellite and nanosatellite size regimes over a wide range of operating wavelengths. In addition, this work will assess the performance penalty incurred by enforcing engineering constraints (monotonically shrinking petals, solid core) presented by previous authors. Finally, the resulting pareto-optimal performance set will be compared to the performance requirements for imaging exoplanet classes of scientific interest. The result of this work will be a comprehensive trade of the capabilities of small-scale occulter/telescope systems, providing a valuable methodology and performance guidelines for future occulter/telescope designs.

9605-40, Session 9

Space telescope design to directly image the habitable zone of Alpha Centauri

Eduardo A. Bendek, Ruslan Belikov, Sandrine J. Thomas, NASA Ames Research Ctr. (United States); Julien Lozi, Subaru Telescope, National Astronomical Observatory of Japan (United States); Jared R. Males, The Univ. of Arizona (United States)

The inner edge of Alpha Cen A&B Habitable Zone is found at exceptionally large angular separations of 0.7" and 0.4" respectively. This enables direct imaging of the system with a 30cm class telescope. Contrast ratios in the order of 1010 are needed to image Earth-brightness planets. Low-resolution (5-band) spectra of all planets, will allow establishing the presence and amount of an atmosphere. This star system configuration is optimal for an specialized small, and stable space telescope, that can achieve high-contrast but has limited resolution. This paper describes an innovative instrument design and a mission concept based on a full Silicon Carbide off-axis telescope, which has a Phase Induce Amplitude Apodization coronagraph embedded in the telescope. This architecture maximizes stability and throughput. The Multi-Star Wave Front algorithm is implemented to drive a deformable mirror controlling simultaneously diffracted light from the on-axis and binary companion star. The instrument has a Focal Plane Occulter to reject starlight into a Low Order Wavefront Sensor that delivers high-precision pointing control. Finally we utilize the ODI post-processing method that takes advantage of a highly stable environment (Earth-trailing orbit) and a continuous sequence of images spanning 2 years, to reduce the final noise floor in post processing to ~2e-11 levels, enabling high confidence and at least 90% completeness detections of Earth-like planets.

9605-41, Session 9

How to directly image a habitable planet around Alpha Centauri with a ~30-45cm space telescope

Ruslan Belikov, Eduardo A. Bendek, Sandrine J. Thomas, NASA Ames Research Ctr. (United States); Jared R. Males, The Univ. of Arizona (United States); Julien Lozi, Subaru Telescope, National Astronomical Observatory of Japan (United States)

Several mission concepts are being studied to directly image planets around nearby stars. It is commonly thought that directly imaging a potentially habitable exoplanet around a Sun-like star requires space telescopes with apertures of at least 1m. A notable exception to this is Alpha Centauri (A and B), which is an extreme outlier among FGKM stars in terms of apparent habitable zone size: the habitable zones are ~3x wider in apparent size than around any other FGKM star. This enables a ~30-45cm visible light space telescope equipped with a modern high performance coronagraph or starshade to resolve the habitable zone at high contrast and directly image any potentially habitable planet that may exist in the system. The raw contrast requirements for such an instrument can be relaxed to 1e-8 if the mission spends 2 years collecting tens of thousands of images on the same target, enabling a factor of 500-1000 speckle suppression in post processing using a new technique called Orbital Difference Imaging (ODI). The raw light leak from both stars is controllable with a special wavefront control algorithm known as Multi-Star Wavefront Control (MSWC), which independently suppresses diffraction and aberrations from both stars using independent modes on the deformable mirror. This paper will present an analysis of the challenges involved with direct imaging of Alpha Centauri with a small telescope and how the above technologies are used together to solve them. We also show examples of small coronagraphic mission concepts currently being developed to take advantage of this opportunity.

9605-42, Session 9

Orbital difference imaging: a new high-contrast post-processing technique for direct imaging of exoplanets

Jared R. Males, The Univ. of Arizona (United States); Ruslan Belikov, Eduardo A. Bendek, NASA Ames Research Ctr. (United States)

Current post-processing techniques in high contrast imaging depend on some source of diversity between the exoplanet signal and the residual star light at that location. The two main techniques are angular differential imaging (ADI), which makes use of parallactic sky rotation to separate planet from star light, and spectral differential imaging (SDI), which makes use of differences in the spectrum of planet and star light and the wavelength dependence of the point spread function (PSF). Here we introduce our technique for exploiting another source of diversity: orbital motion. Given repeated observations of an exoplanetary system with sufficiently short orbital periods, the motion of the planets allows us to discriminate them from the PSF. In addition to using powerful PSF subtraction algorithms, such an observing strategy enables temporal filtering. Once an orbit is determined, the planet can be ``de-orbited'' to further increase the signal-to-noise ratio. We call this collection of techniques Orbital Difference Imaging (ODI). Here we present the motivation for this technique, present a noise model, and present results from simulations. We believe ODI will be an enabling technique for imaging Earth-like planets in the habitable zone with dedicated space missions.

9605-43, Session 9

The low-order wavefront sensor for the PICTURE-C exoplanetary imaging balloon mission

Christopher B. Mendillo, Glenn A. Howe, Timothy A. Cook, Univ. of Massachusetts Lowell (United States); Ewan S. Douglas, Boston Univ. (United States); Susanna C. Finn, Kuravi Hewasawam, Jason Martel, Supriya Chakrabarti, Univ. of Massachusetts Lowell (United States)

The PICTURE-C mission will fly a 60 cm off-axis unobscured telescope and two high-contrast coronagraphs in successive flights with the goal of directly imaging and spectrally characterizing visible scattered light from exozodiacal dust in the interior 1-10 AU of nearby exoplanetary systems. The first flight in 2017 will use a 10^-4 visible nulling coronagraph (previously flown on the PICTURE-B sounding rocket) and the second flight in 2019 will use a 10^-7 vector vortex coronagraph. A low-order wavefront corrector (LOWC) will be used in both flights to remove time-varying aberrations from the coronagraph wavefront. The LOWC actuator is a 76 channel high-stroke deformable mirror packaged on top of a tip-tilt stage. This paper will detail the selection of a high-speed low-order wavefront sensor (LOWFS) for the mission. The relative performance and feasibility of several LOWFS designs will be compared including the Shack-Hartmann, CLOWFS, pyramid, and Zernike phase mask. To model the LOWFS input, a model of the time-varying wavefront is used. This model is driven by measured pointing data and thermal and inertial dynamics models that predict the optical alignment and optical surface deformation in the balloon environment.

9605-44, Session 9

End-to-end simulation of high-contrast imaging systems: methods and results for the PICTURE Mission family

Ewan S. Douglas, Boston Univ. (United States); Kuravi Hewasawam, Christopher B. Mendillo, Univ. of Massachusetts Lowell (United States); Kerri L. Cahoy, Massachusetts Institute of Technology (United States); Timothy A. Cook, Susanna C. Finn, Glenn A. Howe, Univ. of Massachusetts Lowell (United States); Marc J. Kuchner, NASA Goddard Space Flight Ctr. (United States); Nikole K. Lewis, Space Telescope Science Institute (United States); Anne D. Marinan, Massachusetts Institute of Technology (United States); Dimitri Mawet, Jet Propulsion Lab. (United States) and European Southern Observatory (Chile); Supriya Chakrabarti, Univ. of Massachusetts Lowell (United States)

Mission design for high-contrast imaging requires accurate numerical wavefront error propagation to ensure accurate component specifications. For constructed instruments, accurate wavelength and angle dependent throughput and contrast models allow detailed simulations of science observations, allowing mission planners to target the most productive targets.

The PICTURE family of missions seek to quantify the optical brightness of scattered light from extrasolar debris disks via several high contrast imaging techniques; a sounding rocket (the Planet Imaging Concept Testbed Using a Rocket Experiment) and balloon flight of a visible nulling coronagraph, as well as a balloon flight of a vector vortex coronagraph (the Planetary Imaging Concept Testbed Using a Recoverable Experiment - Coronagraph, PICTURE-C). The rocket mission employs an on-axis 0.5m Gregorian, while the balloon flights will share an unobstructed off-axis 0.6m Gregorian design.

We describe the flexible approach to polychromatic, end-to-end physical optics simulation used for both the balloon and rocket missions. We show the PICTURE-C coronagraph design will achieve 10^-7 contrast with post-processing, illustrated by predicted observations of realistic science targets.

9605-45, Session 9

On-ground calibration of the CHEOPS payload

François Wildi, Bruno Chazelas, Adrien Deline, Mirsad Sarajlic , Michael Sordet, Observatoire de Genève (Switzerland)

CHEOPS is a small ESA mission, which purpose is to do extra-solar planets characterization using the photometric transit technique. It is the first ESA S-class mission and will be able to switch from target to target unlike KEPLER or COROT. (http://cheops.unibe.ch/). We are developing a comprehensive support equipment to test, validate and also calibrate the CHEOPS payload before launch. This equipment is quite sophisticated because it has to goal to allow the characterization of the photometric performance of CHEOPS below the 20ppm precision of CHEOPS itself. This paper addresses the goal of the CHEOPS on-ground calibrations as well as the design, performance budget and verification plan of the CHEOPS calibration system.

9605-46, Session 10

The CHARIS IFS for high contrast imaging at Subaru

Tyler D. Groff, N. Jeremy Kasdin, Mary Anne Peters-Limbach, Michael Galvin, Michael A. Carr, Gillian R. Knapp, Princeton Univ. (United States); Timothy D. Brandt, Institute for Advanced Study (United States); Craig Loomis, Norman Jarosik, Princeton Univ. (United States); Kyle Mede, The Univ. of Tokyo (Japan); Michael McElwain, NASA Goddard Space Flight Ctr. (United States); Douglas B. Leviton, Leviton Metrology Solutions (United States); Kevin H. Miller, Manuel A. Quijada, NASA Goddard Space Flight Ctr. (United States); Olivier Guyon, Nemanja Jovanovic, Naruhisa Takato, Subaru Telescope, National Astronomical Observatory of Japan (United States); Masahiko Hayashi, Subaru Telescope, National Astronomical Observatory of Japan (Japan)

The Coronagraphic High Angular Resolution Imaging Spectrograph (CHARIS) is an integral field spectrograph (IFS) being built for the Subaru telescope. CHARIS will take spectra of brown dwarfs and hot Jovian planets in the coronagraphic image provided by the Subaru Coronagraphic Extreme Adaptive Optics (SCExAO) and AO188 adaptive optics systems. The system is designed to detect objects five orders of magnitude dimmer than their parent star down to an 80 milliarcsecond inner working angle. For characterization, CHARIS has a 'high-resolution' prism providing an average spectral resolution of R82, R69, and R82 in J, H, and K bands respectively. The so-called discovery mode uses a second 'low-resolution' prism with an average spectral resolution of R19 spanning 1.15-2.37 microns (J+H+K bands). This is unique compared to other high contrast IFS designs. It augments low inner working angle performance by reducing the separation at which we can rely on spectral differential imaging. The principal challenge for a high-contrast IFS is quasi-static speckles, which cause undue levels of spectral crosstalk. CHARIS has addressed this through several key design aspects that should constrain crosstalk between adjacent spectral features to be below 1%. Sitting on the Nasmyth platform, the alignment between the lenslet array, prism, and detector will be highly stable, key for the performance of the data pipeline. Nearly every component has arrived and the project is entering its final build phase. Here we review the science case, the resulting design, status of final construction, and lessons learned that are directly applicable to future exoplanet instruments.

9605-47, Session 10

Arizona lenslet for exoplanet spectroscopy (ALES): an AO-fed 3-5 micron optimized integral field spectrograph for the LBT

Andrew J. Skemer, Phil M. Hinz, Manny Montoya, The Univ. of Arizona (United States); Olivier Durney, Univ. of Arizona (United States); Michael F. Skrutskie, John C. Wilson, Matt J. Nelson, Univ. of Virginia (United States); Jarron M. Leisenring, The Univ. of Arizona (United States); Charles E. Woodward, Univ. of Minnesota (United States); Denis Defrere, Vanessa P. Bailey, The Univ. of Arizona (United States)

Integral field spectrographs are an important technology for exoplanet imaging, due to their ability to take spectra in a high-contrast environment, and improve planet detection sensitivity through spectral differential imaging. ALES is the first integral field spectrograph capable of imaging exoplanets from 3-5 microns, and will extend our ability to characterize self-luminous exoplanets into a range where they peak in brightness. ALES is installed inside LBTI/LMIRcam on the Large Binocular Telescope, taking advantage of existing AO systems, camera optics, and a Hawaii-2RG detector. The new optics that comprise ALES are a Keplerian magnifier, a silicon lenslet array with diffraction suppressing pinholes, a direct vision prism, and calibration optics. All of these components are installed in filter wheels making ALES a completely modular design.

9605-48, Session 10

High contrast imaging from the ground with combined visible light extreme-AO and fast near-IR speckle control

Olivier Guyon, Nemanja Jovanovic, Julien Lozi, Subaru Telescope, National Astronomical Observatory of Japan (United States); Jared R. Males, The Univ. of Arizona (United States); Garima Singh, Subaru Telescope, National Astronomical Observatory of Japan (United States); Benjamin A. Mazin, Univ. of California, Santa Barbara (United States); Frantz Martinache, Observatoire de la Côte d'Azur (France); Tomoyuki Kudo, Prashant Pathak, Subaru Telescope, National Astronomical Observatory of Japan (United States); Sean Goebel, Univ. of Hawai'i (United States) and Subaru Telescope, National Astronomical Observatory of Japan (United States)

The current generation of Extreme-AO systems is based on high speed visible-light extreme adaptive optics combined with near-IR PSF calibration techniques. In this architecture, the main contributors to residual speckles

are (1) time-lag speckles due to the limited speed of the visible light correction loop, (2) non-common path errors which may be static or slowly varying and (3) chromatic wavefront terms. While these three terms are not strong contributors to the overall wavefront error budget, they create slow speckles that do not average well over typical integration times, and limit current systems' ability to reach high contrast at small angular separations.

We show that by combining a fast (>kHz sampling) visible-light high sensitivity WFS with a fast (~kHz) near-IR post-coronagraphic speckle control loop, all three terms are significantly reduced, allowing 1e-8 contrast to be reached at 50-100 mas on an 8m telescope around bright nearby stars. Predictive control can further improve/extend system performance. This is the strategy adopted by the Subaru Coronagraphic Extreme-AO (SCExAO) system, which combines a 3.5 kHz visible light non-modulated Pyramid WFS using a deep depletion EMCCD with a kHz near-IR speckle control loop using a photon-counting wavelength-resolving MKIDs detector. The same approach, when deployed on Extremely Large Telescopes, will allow direct imaging and spectroscopic characterization of habitable planets around nearby M-type stars.

9605-49, Session 10

An update on the VORTEX project

Olivier Absil, Univ. de Liège (Belgium); Dimitri Mawet, California Institute of Technology (United States); Mikael Karlsson, Uppsala Univ. (Sweden); Serge Habraken, Jean Surdej, Univ. de Liège (Belgium); Pierre-Antoine Absil, Univ. Catholique de Louvain (Belgium); Brunella Carlomagno, Univ. de Liège (Belgium); Valentin Christiaens, Univ. de Chile (Chile) and Univ. de Liège (Belgium); Denis Defrère, The Univ. of Arizona (United States); Pontus Forsberg, Uppsala Univ. (Sweden); Julien H. V. Girard, European Southern Observatory (Chile); Carlos A. Gomez Gonzalez, Univ. de Liège (Belgium); Philip M. Hinz, The Univ. of Arizona (United States); Elsa Huby, Aïssa Jolivet, Univ. de Liège (Belgium); Julien Milli, European Southern Observatory (Chile); Eric J. Pantin, CEA-Ctr. de SACLAY (France); Garreth J. Ruane, Rochester Institute of Technology (United States); Eugene Serabyn, Jet Propulsion Lab. (United States); Marc Van Droogenbroeck, Univ. de Liège (Belgium); Ernesto Vargas Catalan, Uppsala Univ. (Sweden); Olivier Wertz, Univ. de Liège (Belgium)

In this talk, we will review the on-going activities within the VORTEX team at the University of Liège and Uppsala University. The VORTEX project aims to design, manufacture, test, and exploit vector vortex phase masks made of sub-wavelength gratings (aka the Annular Groove Phase Mask, AGPM) for the direct detection and characterization of extrasolar planets. This talk will specifically report on the commissioning of several AGPMs on infrared cameras equipping 10-m class telescopes, including the VLT, the LBT and the Keck. We will describe the in-lab and on-sky performance of the AGPMs, and discuss first scientific observations. We will also report on the lessons learned from the on-sky operation of our vortices, and discuss ways to improve their performance. The potential of our coronagraphic devices in the context of future extremely large telescopes and space missions will also be addressed.

9605-50, Session 11

Exoplanet science with the LBTI: instrument status and plans

Denis Defrère, Philip M. Hinz, Andrew J. Skemer, Vanessa P. Bailey, Elwood C. Downey, Olivier Durney, John M. Hill, William F. Hoffmann, Jarron M. Leisenring, The Univ. of Arizona (United States); Bertrand Mennesson, Jet Propulsion Lab. (United States); Rafael Millan-Gabet, Infrared Processing and Analysis Ctr. (United States); Manny Montoya, The Univ. of Arizona (United States); Michael F. Skrutskie, Univ. of Virginia (United States); Eckhart Spalding, Amali Vaz, The Univ. of Arizona (United States)

The Large Binocular Telescope Interferometer (LBTI) is a strategic instrument of the LBT designed for high-sensitivity, high-contrast, and high-resolution infrared imaging of nearby planetary systems, operating at infrared wavelengths (1.5 to 13 ?m). To carry out a wide range of high-spatial resolution observations, it can combine the two AO-corrected 8.4-m apertures of the LBT in various ways including direct (non-interferometric) imaging, coronagraphy, Fizeau imaging, non-redundant aperture masking,

and nulling interferometry; and has broadband, narrowband or spectrally dispersed capabilities. In this paper, we review the performance of these modes in terms of exoplanet science capabilities and describe recent instrumental milestones such as first-light Fizeau images (with the angular resolution of an equivalent 22.7-m telescope) and interferometric nulling observations.

9605-51, Session 11

Post processing for direct imaging: characterizing noise properties and astrophysical sources in modern ground based coronagraphs

Laurent A. Pueyo, Space Telescope Science Institute (United States)

In this paper we present recent progress on data analysis of modern ground based coronagraph aimed at detecting and characterizing exo-planets. We first discuss the overall architecture of such instruments, that combine an Extreme Adaptive Optics system, an optimized coronagraph, low and high-order wavefront sensors and use an Integral Field Spectrograph. In this context we quantify the temporal and chromatic properties of the residual noise associated with imperfections in the optics, their correlation with wavefront sensing and control performances. We discuss post-processing strategies to subtract these speckles in order to detect exo-plantes and circumstellar structures buried under the diffracted stellar light. We then describe the intricacies associated with spectroscopy and astrometry estimation and present two recent algorithms. The first one retrieves the stellar focal plane position when the star is occulted by a coronagraphic stop. The second one yields precise astrometry and spectro-photometry estimates of faint point sources even when they are initially buried in the speckle noise. We finally highlight recent scientific results obtained using these methods.

9605-52, Session 11

Optimized pupil and focal plane phase elements for vortex coronagraphs on telescopes with obstructed apertures

Garreth J. Ruane, Rochester Institute of Technology (United States); Elsa Huby, Univ. de Liège (Belgium); Christian Delacroix, Ctr. de Recherche Astrophysique de Lyon (France); Dimitri Mawet, Jet Propulsion Lab. (United States); Olivier Absil, Univ. de Liège (Belgium); Grover A. Swartzlander Jr., Rochester Institute of Technology (United States)

We present a technique for optimizing pupil and focal plane phase elements for vortex coronagraphs on telescopes with obstructed apertures. The phase elements are calculated numerically using a point-by-point iterative phase retrieval algorithm. Two example designs for the future European Extremely Large Telescope (E-ELT) and the Thirty Meter Telescope (TMT) are described. The first design applies a phase correction to the focal plane element in order to improve the starlight suppression of a conventional vortex coronagraph. The second design introduces a phase element after the Lyot stop to modify the residual on-axis point spread function and improve the contrast in a pre-defined region of the image plane. We analyze the performance of these designs in terms of contrast and off-axis image quality. Limitations set by chromatic effects and manufacturing constraints are also explored.

9605-53, Session 11

A Mach-Zehnder interferometer based on orbital angular momentum for improved vortex coronagraph efficiency

Pierre Piron, Univ. de Liège (Belgium); Christian Delacroix, Ctr. de Recherche Astrophysique de Lyon (France); Elsa Huby, Univ. de Liège (Belgium); Dimitri Mawet, Jet Propulsion Lab. (United States); Aïssa Jolivet, Brunella Carlomagno, Serge Habraken, Olivier Absil, Jean Surdej, Univ. de Liège (Belgium)

When used as coronagraphs, vortex phase masks provide a continuous helical phase ramp for on-axis input light, which leads to the creation of orbital angular momentum (OAM). Thanks to that helical phase, the intensity of the central source is rejected outside the geometrical pupil in a subsequent pupil plane, while off-axis sources located beyond an angular distance of lambda/D are mostly unaffected. However, due to wave front imperfections, the on-axis light rejection is not perfect. To improve on-axis light rejection, a Mach-Zehnder interferometer containing Dove prisms differently oriented has recently been proposed to sort photons based on their OAM (Riaud 2014).

In this paper, we will develop the mathematical model of the wave front propagation in the Mach-Zehnder interferometer using the Jones formalism. Based on our model, we show that the performance of this setup is limited to a 10-fold increase in the on-axis light rejection due the Dove prism birefringence. We propose and evaluate possible ways to improve the interferometer performance, including the addition of a birefringent wave-plate in each arms to compensate for the Dove prism birefringence. The effect of the birefringent plate is mathematically described and used to reassess the performance. Finally, we discuss the sensitivity of the interferometer performance to several experimental conditions, such as the central obstruction and the imperfections of the AGPM.

9605-54, Session 11

A family of subwavelength grating vortex coronagraphs (SGVCs) with higher topological charge

Christian Delacroix, Ctr. de Recherche Astrophysique de Lyon (France); Pontus Forsberg, Uppsala Univ. (Sweden); Pierre Piron, Univ. de Liège (Belgium); Garreth J. Ruane, Rochester Institute of Technology (United States); Elsa Huby, Brunella Carlomagno, Aïssa Jolivet, Univ. de Liège (Belgium); Ernesto Vargas, Uppsala Univ. (Sweden); Olivier Absil, Univ. de Liège (Belgium); Dimitri Mawet, European Southern Observatory (Chile); Mikael Karlsson, Uppsala Univ. (Sweden); Jean Surdej, Serge Habraken, Univ. de Liège (Belgium)

The subwavelength grating vortex coronagraph (SGVC) is a focal-plane spiral-like phase mask whose key benefit is to allow high contrast imaging at small angles. Directly etched onto a CVD diamond substrate, it is well suited to perform in the mid-infrared domain. It provides a continuous helical phase ramp with a dark singularity in its center, and is characterized by its number of phase revolutions, called the topological charge. Over the past two years, we have manufactured several charge-2 SGVCs (a.k.a. annular groove phase masks) and successfully demonstrated their performances on 10-m class telescopes (LBT, VLT/NaCo, VLT/VISIR). To prevent stellar leakage on future 30-m class telescopes (E-ELT, TMT, GMT), a broader off-axis extinction is required, which can be achieved by increasing the topological charge. We have recently proposed an original design for a charge-4 SGVC allowing less starlight to leak through the coronagraph, at the cost of a degraded inner working angle. In this talk, we report on our latest development of higher charge SGVCs. From 3D rigorous numerical simulations using a finite-difference time-domain (FDTD) algorithm, we

have derived a family of coronagraphs with higher topological charge (SGVC4/6/8). Our new optimization method addresses the principal limitation of such space-variant polarization state manipulation, i.e., the inconvenient discontinuities in the discrete grating pattern. The resulting gratings offer improved precision to the phase modulation compared to previous designs. Finally, we present our preliminary manufacturing and metrology results for infrared components down to the K-band.

9605-55, Session 11

ExTrA

Jose Manuel Almenara, Xavier Bonfils, Laurent Jocou, Institut de Planétologie et d'Astrophysique de Grenoble (France); Anael Wunsche, Institut d'Informatique et Mathématiques Appliquées de Grenoble (France); Pierre Kern, Alain Delboulbé, Philippe Feautrier, Laurence Gluck, Sylvain Lafrasse, Yves Magnard, Didier Maurel, Thibaut Moulin, Felipe Murgas, Patrick Rabou, Sylvain Rochat, Alain Roux, Eric Stadler, Institut de Planétologie et d'Astrophysique de Grenoble (France)

ExTrA is an ERC-funded project offering a novel method to dramatically improve on the precision of ground based photometry and more efficiently search for exo-Earths orbiting cool stars. The method makes use of a multi-object spectrograph to add the spectroscopic resolution to the traditional differential photometry method. We will discuss how this shall enable the fine correction of color-dependent systematics (atmospheric variations, instrument and detector errors) that would otherwise hinder ground-based observations.

ExTrA aims to develop this method with a new facility composed of three small telescopes (60cm in diameter) and a near-infrared spectrograph (R<500, lbda=0.8-1.6 ?m). Near-infrared observations will boost the efficiency of its cool-star observations, such that ExTrA might become the most sensitive survey for Earth-size planets transiting nearby planets. It shall yield dozens exo-Earths amenable to atmospheric characterization, including several exo-Earths in the habitable zone, which may provide our first peek into an exolife laboratory. In addition, ExTrA might prove to be powerful in following-up K2, TESS and PLATO candidates.

In this talk, we shall discuss all aspects of ExTrA from its concept to the expected exoplanet yield, passing by its design, feasibility laboratory tests, and implementation.

9605-56, Session 12

iLocater: a high-resolution, near-infrared Doppler spectrometer for the large binocular telescope

Justin R. Crepp, Eric Bechter, Erica Gonzales, Edward Kielb, Andrew Bechter, Jonathan Crass, Jay Carroll, Ryan Ketterer, John Brooks, Univ. of Notre Dame (United States); Robert O. Reynolds, Large Binocular Telescope Observatory (United States); Phil M. Hinz, The Univ. of Arizona (United States); Michael F. Skrutskie, Univ. of Virginia (United States); Joshua Eisner, The Univ. of Arizona (United States); Louis G. Fantano, NASA Goddard Space Flight Ctr. (United States); B. Scott Gaudi, The Ohio State Univ. (United States); David Go, John Kearns, Univ. of Notre Dame (United States); David M. P. King, Univ. of Cambridge (United States); Corina Koca, NASA Goddard Space Flight Ctr. (United States); Kaitlin Kratter, The Univ. of Arizona (United States); Christopher Matthews, Univ. of Notre Dame (United States); Giuseppina Micela, INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Andreas Quirrenbach, Landessternwarte Heidelberg (Germany); Alessandro Sozzetti, INAF - Osservatorio Astronomico di Torino (Italy); Karl Stapelfeldt, NASA Goddard Space Flight Ctr. (United States); Darren Williams, The Pennsylvania State Univ. (United States); Charles E. Woodward, Univ. of Minnesota, Twin Cities (United States); Bo Zhao, Univ. of Florida (United States); Isabella Pagano, INAF - Osservatorio Astrofisico di Catania (Italy)

iLocater will soon become the world's first diffraction-limited Doppler spectrometer. An infrared-optimized, high resolution planet-finding spectrograph recently approved for construction at the Large Binocular Telescope, iLocater is the first radial velocity instrument that will use "extreme" adaptive optics to inject starlight into single mode optical fibers. In addition to completely eliminating modal noise, iLocater will also reduce background contamination from OH-emission lines by two orders of magnitude compared to seeing-limited instruments, use an Invar design to relax temperature control requirements by an order of magnitude, and use two 8.4m telescope dishes simultaneously to monitor and remove internal velocity errors. In this presentation, we discuss iLocater's expected performance and science return.

9605-57, Session 12

First results of instrumental stability using an astro frequency comb at the foces spectrograph

Frank U. Grupp, Univ.-Sternwarte München (Germany) and Max-Planck-Institut für extraterrestrische Physik (Germany); Anna Brucalassi, Max-Planck-Institut für extraterrestrische Physik (Germany); Hanna Kellermann, Univ.-Sternwarte München (Germany); Ronald Holzwarth, Tilo Steinmetz, Menlo Systems GmbH (Germany); Ulrich Hopp, Univ-Sternwarte München (Germany); Ralf Bender, Max-Planck-Institut für extraterrestrische Physik (Germany)

Since January 2015 the R=70000 FOCES Echelle spectrograph is equipped by an Astro Frequency COMB. With this paper we present first results on the instrument stability measured by this "perfect calibrator". As FOCES is equipped with temperature and pressure stabilization, the Frequency Comb allows to test the stability models and predictions of pressure and temperature sensitivity. In addition, the stability of the thermo-electrically cooled FOCES CCD system will be presented.

9605-58, Session 12

Effects of fiber manipulation methods on optical fiber properties

Robert O. Reynolds, Large Binocular Telescope Observatory (United States)

Optical fibers are now routinely used to couple high-resolution spectrographs to modern telescopes, enabling important advantages in areas such as the search for extrasolar planets using spectroscopic radial velocity measurements of candidate stars. Optical fibers partially scramble the input illumination, and this phenomenon enables a fiber feed to provide more uniform illumination to the spectrograph optics, thereby reducing systematic errors in radial velocity measurements. Current instruments now achieve a precision of ~1m/s using fiber-feeds, but greater precision approaching 10cm/s is required to detect terrestrial planets orbiting sun-like stars. A primary limiting factor in multimode fiber coupling is modal noise, a measurement uncertainty caused by inherent properties of optical fibers, evident as a varying spatial intensity at the fiber exit plane. Many

instruments utilize the strategy of agitating the fiber during an observation to reduce modal noise, and squeezing of the fiber and dynamical optical diffusers have been tested as alternatives to agitation. However, deformation of the fiber can lead to light loss, and diffusers may be suitable only for calibration sources due to known losses. The technique of stretching or varying the length of the fiber has been shown to offer advantages over other approaches, but effects of stretching on fiber parameters such as total transmission and focal ratio degradation have not been adequately studied. In this paper we present results of measurement of transmission loss and focal ratio degradation in a stretched fiber, along with discussion of possible consequences.

9605-59, Session 13

Archival legacy investigation of circumstellar environments (ALICE): statistical analysis of high-contrast images of 400 stars with HST-NICMOS

Élodie Choquet, Rémi Soummer, Laurent A. Pueyo, J. Brendan Hagan, Elena Gofas-Salas, Marshall D. Perrin, Christine Chen, John H. Debes, David A. Golimowski, Dean C. Hines, Space Telescope Science Institute (United States); Glenn H. Schneider, The Univ. of Arizona (United States); Amaya Moro-Martin, Space Telescope Science Institute (United States); Christian Marois, NRC-Dominion Astrophysical Observatory (Canada); Dimitri Mawet, European Southern Observatory (Chile); Mamadou N'Diaye, Space Telescope Science Institute (United States); Abhijith Rajan, Arizona State Univ. (United States); Schuyler G. Wolff, Jonathan Aguilar, Alexandra Z. Greenbaum, Johns Hopkins Univ. (United States); Tushar Mittal, Univ. of California, Berkeley (United States); Bin Ren, Johns Hopkins Univ. (United States)

We are currently conducting a comprehensive and consistent re-processing of archival HST-NICMOS coronagraphic surveys using advanced PSF subtraction methods, entitled the Archival Legacy Investigation of Circumstellar Environments program (ALICE, HST/AR 12652). This virtual campaign of about 400 stars observed between 1998 and 2008 has already produced numerous new detections of previously unidentified point sources and circumstellar structures (both protoplanetary disks and debris disks). We present an overview of the objects detected as part of this program and report on follow-up status for the companion candidates, and characterization status for the circumstellar disks. We also estimate the number of exoplanets in our candidate sample, based on background source probability from stellar population models. Finally, we discuss the preliminary statistical constraints ALICE places on the occurrence of brown dwarf and exoplanet companions around nearby stars. Since the methods developed as part of ALICE are directly applicable to future missions (JWST, AFTA coronagraph) we emphasize the importance of devising optimal PSF subtraction methods for upcoming coronagraphic imaging missions. We describe efforts in defining direct imaging high-level science product (HLSP) standards that can be applicable to other coronagraphic campaigns, including ground-based (e.g., Gemini Planet Imager, SPHERE, ELTs), and future space instruments (e.g., JWST).

Conference 9606: Instruments, Methods, and Missions for Astrobiology XVII

SPIE. OPTICS+ PHOTONICS OPTICAL ENGINEERING+ APPLICATIONS

Sunday - Tuesday 9 –11 August 2015

Part of Proceedings of SPIE Vol. 9606 Instruments, Methods, and Missions for Astrobiology XVII

9606-1, Session 1

The centenary of the birth of Fred Hoyle, a landmark event in astrobiology

Chandra N. Wickramasinghe, The Univ. of Buckingham (United Kingdom) and Institute for the Study of Panspermia and Astroeconomics (Japan) and Univ. of Peradeniya (Sri Lanka); G. Tokoro, Institute for the Study of Panspermia and Astroeconomics (Japan); Brig Klyce, Astrobiology Research Trust (United States)

The setting up of the Institute for the Study of Panspermia and Astroeconomics (ISPA) in Japan in the centenary year of Fred Hoyle marks an important step in the progress of a field of study pioneered by Hoyle. Panspermia theory in the form it was developed by Hoyle and one of the present authors (NCW) has recently been gaining support from a wide range of studies, but is still being resisted to varying degrees by mainstream science. The website managed by one of us (BK) has attempted to record the new data and chronicle the ensuing debate. The aim of ISPA will be monitor the stratosphere with balloon-borne detectors for viruses and bacteria that might unequivocally demonstrate their space origin. The present tendency to ignore data that supports panspermia appears to be deep-rooted in economic incentives to maintain the status quo. With the arrival of more data a paradigm shift from Earth-centred to cosmic-centred life will become increasingly likely. The present year is already bringing a wealth of new supportive data for panspermia.

9606-2, Session 2

Is life supernatural? *(Invited Paper)*

Gilbert V. Levin, Arizona State Univ. (United States)

The big question of the origin of life is examined. The paradox of Pasteur's dictum "Life only comes from life," and the need for spontaneous generation is explored. This seemingly dead end conundrum contrasts sharply with the great progress we have made in understanding the evolution of the species since Darwin's revolutionary insight. The conditions that promoted non-living molecules and compounds to cross the sharp line from inert to life is contemplated. Future prospects for solving this penultimate mystery, with some suggestions for experiments, are conjectured with the objective of promoting much needed discussion on this key issue.

9606-3, Session 2

Oparin's coacervates as an important milestone in chemical evolution *(Invited Paper)*

Vera M. Kolb, Univ. of Wisconsin-Parkside (United States)

We summarize first some traditional views on the milestones in chemical evolution which led to life. Then we focus on Oparin's coacervates as one such milestone. We review our recent work in which we have shown that Oparin's coacervates can serve as prebiotic chemical reactors. We then present Oparin's views on chemical evolution via his coacervates, and show that they are still valid. He has pointed out a competition between coacervates for "food", namely chemicals from the prebiotic soup, a selection process which gives advantage to coacervates which have useful catalysts that enable them to synthesize their own "food", and finally more sophisticated coacervates which ultimately acquire capability to synthesize primitive information molecules that will preserve chemical knowledge of the system.

9606-4, Session 2

Philosophy of astrobiology: Some recent developments

Vera M. Kolb, Univ. of Wisconsin-Parkside (United States)

We present some recent developments in philosophy of astrobiology to illustrate usefulness of philosophy to astrobiology. Our examples include philosophical applications to the definition of life and chemical evolution. We include Aristotelian views, dialetheism, and the philosophical analysis by Iris Fry about the beginning of natural selection in prebiotic world.

9606-5, Session 2

How to survive a late heavy bombardment

Gregory A. Konesky, National Nanotech Inc. (United States)

The disparity of the radiometric age of the Earth and the age of the oldest rock formations was addressed by the Apollo Lunar samples which strongly supported the idea of a Late Heavy Bombardment which essentially resurfaced the Earth. Zircon mineral grains, which predate the LHB, grow by concretion and occasionally entrap samples of their immediate environment as inclusions, and reveal the presence of oceans on Earth prior to the LHB. Suppose life originated prior to the LHB, but any microfossil evidence of it would have been erased by that event. While the oldest microfossils, as evidenced by carbon-13 depletion relative to carbon-12, might suggest a recurrent origination of life, we consider how still earlier life could have survived in the deep hot biosphere and re-emerged at the end of the LHB, reestablishing life on the surface of the Earth. We review the deep hot biosphere as it exists today and consider the dynamics of the LHB in terms of frequency and size of impacts to show that the putative "first" life to originate prior to the LHB could have survived this event. Indeed, we consider the environment of the early pre-LHB Earth and find it more favorable to the origination of life than the post-LHB.

9606-6, Session 3

Bioluminescent bacteria grown under modelled gravity of different astronomical bodies in the solar system *(Invited Paper)*

Santosh Bhaskaran, Vivekanand Education Society College of Arts, Science and Commerce (India) and Savitribai Phule Pune Univ. (India); Rohan D. Dudhale, P.E.S. Modern College of Arts, Science and Commerce (India) and Haffkine Institute (India); Jyotsana P. Dixit, P.E.S. Modern College of Arts, Science and Commerce (India) and Savitribai Phule Pune Univ. (India); Ajit N. Sahasrabuddhe, P.E.S. Modern College of Arts, Science and Commerce (India) and Serum Institute of India (India); Pandit B. Vidyasagar, Savitribai Phule Pune Univ. (India) and Swami Ramanand Teerth Marathwada Univ. (India)

Vibrio harveyi (strain NB0903), a bioluminescent bacterium, were exposed to modelled gravity conditions viz. Microgravity (Space), 0.16 g (Lunar), 0.38 g (Martian), 1 g (Earth) as dynamic control and 2.5 g (Jovian) for 15 hours using a clinostat-centrifuge system. The suspension culture was adjusted to OD = 0.2 (approx. 5x10^9 cells/ml) and 1% inoculum added to sterile BOSS broth (Klein et al., 1998) in each of four identical glass vessels specially designed for the system. Two of these cultures were exposed to altered gravity. The other two cultures acted as static controls. At regular

intervals of one hour, aliquots were taken for measuring optical density at 590 nm using a digital colorimeter. Both control and test vessels were shaken well before taking the aliquots so that the cultures were well-mixed. All experiments were carried out at room temperature (25±1 °C). Each experiment was repeated three times and consistent results were obtained.

Comparison of OD showed maximum growth in modelled lunar gravity followed by modelled microgravity compared to static control. This was followed by modelled Martian gravity, Earth's gravity/ dynamic control and Jovian gravity compared to static control. Thus modelled Lunar gravity appears to be most favourable for the growth of Vibrio harveyi. Similar studies on mammalian cells are important, since they will provide an insight as to how our physiological systems will adapt to such gravity conditions. This can be used in industry to get maximum output from micro-organisms just by optimising the value of g in addition to pH, temperature, etc.

9606-7, Session 3

Exomoon habitability

Gregory A. Konesky, National Nanotech Inc. (United States)

The highly successful transit method for detecting exoplanets can also provide evidence for the possible presence of exomoons by variations in the transit timing, caused by the motions of exomoons around the host exoplanet. We consider two categories of habitable exomoons. One is where the exomoon/exoplanet system in within the habitable zone of the host star, even though the exoplanet itself may be unsuitable for life, such as a gas giant. Another category of habitable exomoon is where the habitable conditions are maintained by tidal heating as it orbits the host exoplanet. Such habitability is independent of illumination from the host star. In the early phases of the formation of a solar system, large numbers of planets may form which, through gravitational encounters with each other, have been ejected from the solar system, and today wander interstellar space, far from any host star. Yet exomoons orbiting these wandering or "rogue" planets may remain habitable due to tidal heating. It is estimated that the number of rogue planets exceeds the number of stars in our galaxy by at least an order of magnitude. We also consider the role of Earth's Moon in establishing and maintaining conditions for the development of advanced life forms. When viewed over interstellar distances, the Earth-Moon system might well be considered a double or binary planet. If this is a necessary criterion for the development of advanced life forms, then simple basic life may be quite common in the universe, but advanced forms may be exceedingly rare.

9606-8, Session 4

The search for extra-terrestrial intelligence: current status and future prospects *(Invited Paper)*

Stuart Bowyer, Univ. of California, Berkeley (United States)

The idea that credible searches for Extra-Terrestrial Intelligence (ETI) could be carried out using the radio band were laid out in detail in a classic paper by Morrison and Cocconi (1959). Since then radio searches have been carried out by over sixty different groups. No signals from ETIs have been identified. Most searches did not have high sensitivity so it is not surprising that no ETI signals were detected. Within the last few years, important new ideas regarding the existence of ETI have evolved. New radio instrumentation with greatly superior sensitivity has been developed, new information on the existence of possible sites for ETI (especially in regards to planetary sites) has been found, and new types of searches have been suggested. A major discovery of import was the detection of a surprising number of planetary systems. This increases the potential locations for extraterrestrial intelligence. However, the systems that have been discovered show that the formation of planetary systems is complex and results in many systems that are unstable. In a worst case scenario for the Search for Extra-Terestrial Intelligence (SETI), there will be far more stars with planetary systems but few planets with appropriate orbits. An additional complexity is the requirement, based on very general grounds, that water is a necessity for the development of life. But the origin of water on Earth is unclear and may not occur in other planets. Despite these uncertainties most workers in the field continue to be optimistic regarding the possibility of eventually detecting an ETI signal. In this paper I review these issues.

9606-9, Session 4

The next phases of SETI@home

Eric J. Korpela, Andrew P. V. Siemion, Dan Werthimer, Univ. of California, Berkeley (United States); Matt Lebofsky, Space Sciences Lab. (United States); Jeff Cobb, Univ. of California, Berkeley (United States)

The SETI@home project, which has been underway since May 1999 is the largest volunteer computing project in existence. Over 9 million people have signed up since its introduction. Since its release, multiple enhancements have been made which better utilize the capabilities of the computers running SETI@home including ports to graphics processing units (GPU) and ports to Android devices including mobile phones. We are preparing a new release of SETI@home entirely rewritten. It will include full stokes parameterization of signals, and RFI rejection using cross polarization and cross beam techniques. It will, whenever possible, be data source agnostic. I will describe the state of development and plans for its release.

9606-10, Session 5

The universal alien and the case for our Martian origins *(Invited Paper)*

Steven Albert Benner, The Foundation For Applied Molecular Evolution (United States)

A survey of ongoing activities seeking to understand the origin of life on Earth finds today much that would have been familiar half a century ago to Leslie Orgel, Jim Ferris, Stanley Miller, and other heroes of the field. Pathways are still being sought to get simple biological molecules (amino acids, nucleosides and nucleotides) from a "prebiotic soup" containing the same organic building blocks that have been identified for years. Laboratories are still attempting to get RNA to be synthesized on template RNA from activated building blocks, much as Orgel attempted in the 1960s. The same kinds of lipids are being sought to create much the same compartments as were sought in the classical era of "origins". Today's experiments are, of course, easier because of recent advances in technology. However, the fact that the questions being asked would be familiar to those who asked them a half-century ago is disappointing, and is prompting many organizations, including the John Templeton Foundation, to seek research directions that embody new concepts.

One new concept recognizes that the terran biochemistry need not be universal. Work in synthetic biology has taught us that other biopolymers can perform the roles that DNA, RNA, and proteins perform in the life that we know here on Earth. Accordingly, it is necessary to extract general principles about how Darwinian evolution might be done in life that does not share a common ancestry with life on Earth. This concept of the "universal alien" must then be extended to origins as well. Here, the universal rules of chemistry create suggest some paradoxes. For example, water appears to be a particularly good solvent for life. At the same time, the biopolymers that we know in life on Earth are easily corroded by water. The only reason why we survive today in water is because we have repair systems that constantly fix the damage that water is doing to our nucleic acids and proteins.

Those repair systems almost certainly did not arise together with the first Darwinian systems. Further, the inventory of water on early Earth appears to be too excessive to permit many of the chemical reactions that we most favor to create the first life forms. Interestingly, the inventory of water on Mars was never as high, and Mars contains certain minerals (including those containing elements such as boron) that could function in a semi arid environment, but never on a flooded planet.

This talk will present the case to the layperson for a universal biochemistry, and the possibility that it could have been established on Mars, only to come

from Mars to Earth to be our ancestors after it was safely established.

9606-11, Session 5

Prebiotic reactions in superheated water

Vera M. Kolb, Univ. of Wisconsin-Parkside (United States)

Water changes its properties when superheated and behaves more like an organic solvent. Thus, numerous organic reactions occur in superheated water, which do not occur readily in water under normal conditions. Functional group transformations which occur in water at elevated temperatures and pressures are directly related to the chemical syntheses in hydrothermal vents. We review key properties of superheated water and select the reactions which occur readily in this medium and which are of prebiotic importance.

9606-12, Session 5

The bioinformatics of nucleotide sequence coding for proteins requiring metal coenzymes and proteins embedded with metals *(Invited Paper)*

George Tremberger Jr., Sunil Dehipawala, Andrew Nguyen, Todd Holden, David Lieberman, Tak D. Cheung, Queensborough Community College (United States)

All metallo-proteins (proteins embedded with metals) require post-translation metal incorporation in order to perform their functions. The measurement of isotope ratios of iron, copper, and zinc has emerged as an important tool in the fields of physiology and oncology. The random nature in which metals are assimilated in proteins can be studied in terms of nucleotide sequence complexity. The inside-out theory for the emergence of eukaryotic cells via bleb formation as proposed by Baum (BMC Bio 2014 Oct 28) has been found to be consistent with the view that the activity of metals are critical for the evolution of life. The isotope ratio of Carbon-12 to Carbon-13 has been used to bolster support for a recent theory that establishes the origin of life on Earth at 4 billion years BP. The hypothesis that early methanogens would favor releasing Carbon-12 while retaining Carbon-13 finds support in the isotope ratio results reported in physiology and oncology studies. The nickel-containing F430 is the prosthetic group of the enzyme methyl coenzyme M reductase, which catalyzes the release of methane in the final step of methanogenesis. Sequences requiring metal-embedded coenzymes have also been studied in terms of bioinformatics complexity as measured by fractal dimension and entropy. The results are consistent with the idea that metal-embedded coenzymes could act as life switches. The evolutionary advantage of metallo-proteins and proteins with metal-embedded coenzymes in the contexts of molecular crowding and the RNA granule dynamical cytoplasm is also discussed.

9606-13, Session 5

The advantage of dynamic, covalent bonds in the formation and evolution of proto-RNA *(Invited Paper)*

Nicholas V. Hud, Georgia Institute of Technology (United States)

The RNA World hypothesis remains popular among many origins of life researchers. However, a prebiotic synthesis of RNA has not been demonstrated. Significant challenges facing the prebiotic formation of RNA polymers include nucleobase selection, sugar selection, nucleoside bond formation, and nucleotide polymerization. We are investigating the hypothesis that RNA was preceded by a polymer that would have assembled more easily than RNA, a hypothetical polymer that we refer to as proto-RNA. This primitive genetic polymer (or polymers) would have had a different backbone and different nucleobases. Each component of proto-RNA would have been changed over the course of time by chemical and biological evolution, most likely through a series of intermediate pre-RNAs. In support of this hypothesis, recent advances in our laboratory have revealed that alternative, plausibly prebiotic nucleobases can self-assemble in water and readily form nucleosides with ribose, two properties not observed with the nucleobases currently found in RNA. In addition to molecular selection by noncovalent interactions, which is common in self-assembly, we are also finding that dynamic, covalent bonds allow for the selection of molecules and structures that could have facilitated and greatly accelerated the emergence and evolution of the first biopolymers.

9606-14, Session 6

Ribosome dynamics and the evolutionary history of ribosomes *(Invited Paper)*

George E. Fox, Maxim Paci, Quyen Tran, Univ. of Houston (United States)

The modern ribosome is a dynamic nanomachine responsible for coded peptide synthesis in modern cells. The major ribosomal subsystems were essentially in place at the time of the last universal common ancestor (LUCA) and ribosome evolutionary history thus provides a window into the pre- LUCA world. The large ribosomal RNAs (rRNAs) grew in size over time and recent studies show that the growth mechanisms were likely the same in the pre- and post-LUCA time periods. This understanding has allowed development of a detailed model for the relative age of each helical segment in the rRNAs. A key ribosomal component is the transfer RNAs that bring activated amino acids into the ribosomal A-site. There is a hinge like structure (pivot point) in each tRNA that allows it to rotate from the A- site, to the P- site and ultimately the E site from which it exits the ribosome. Large numbers of high resolution ribosome structures and ribosomal subunits in different states are now available. We have used this information to identify the location of 21 additional pivot points in the large rRNAs. When examined in the context of helix age, these pivots appear to have been added in a similar time period, which likely was after the addition of the tRNA hinge. In particular, there appears to be a portion of the small subunit RNA that may be inherently flexible. The addition of this segment and the tRNA hinge would have made mRNA moment and hence coded peptide synthesis possible.

9606-15, Session 6

The complexity of genetic sequences modified by horizontal gene transfer

George Tremberger Jr., Sunil Dehipawala, Andrew Nguyen, Todd Holden, David Lieberman, Tak D. Cheung, Queensborough Community College (United States)

Horizontal gene transfer is an important and efficient means of moving genetic material among living species and could serve as a pathway for the incorporation of non-coding DNA into a genome. Our previous study of lnc-RNA sequence complexity using fractal dimension and information entropy analysis shows a strongly regulated trend among the studied genes in numerous diseases. Sequence complexity due to retrovirus-related horizontal gene transfer has been investigated in several symbiotic species living within the mealybug (www.cell.com/abstract/S0092-8674%2813%2900646-6). A recent study on Gamma Ray Bursts, which suggests that a redshift of z< 0.5 is the earliest time when life could emerge in the universe, proposes that radiation resistance in genomes is of foremost importance (On the role of GRBs on life extinction in the Universe, Phys. Rev. Lett. 113, 231102, 2014). Research supporting the view that the origin of asteroids is the result of planet formation strengthens a solar-origin hypothesis for the emergence of a radiation resistance gene at time z<0.5. The interpretation that non-coding gene transcription differences in Deinococcus radiodurans exposed to ionizing radiation would give rise to global gene regulation (Transcriptional Analysis of Deinococcus radiodurans Reveal Novel sRNAs that are Differentially Expressed under

Ionizing Radiation. Appl Environ Microbiol. 2014 Dec 29) is analyzed from a bioinformatics perspective in this project. The likelihood that DR radiation repair sequences underwent horizontal gene transfer is also discussed.

9606-16, Session 6

Mutation, but not random

Brig Klyce, Astrobiology Research Trust (United States)

The strongest version of panspermia holds that life on Earth comes from elsewhere, and all the genetic programs for evolution to higher life forms likewise must ultimately come from elsewhere. Once the programs are supplied, darwinian mutation-and-selection can test and optimise them. The needed mutations can be sped up by stress; this process is called adaptive mutation. If the mutations are confined to appropriate DNA segments, as usual, that is called directed mutation. But for significant evolutionary progress, horizontal gene transfer is essential. New evidence suggests that some bacteria can actively induce other species to donate their genes to the inducers. In these ways, evolution benefits from mutations that are far from random.

9606-17, Session 7

Possible effects of diagenesis on the stable isotope composition of amino acids in carbonaceous meteorites *(Invited Paper)*

Michael H. Engel, The Univ. of Oklahoma (United States)

The initial report of indigenous, non-racemic protein amino acids (L-enantiomer excess) in the Murchison meteorite was based on the fact that only eight of the 20 amino acids characteristic of all life on Earth was present in this stone (Engel and Nagy, 1982). The absence of the other protein amino acids indicated that contamination subsequent to impact was highly unlikely. The development of new techniques for determining the stable isotope composition of individual amino acid enantiomers in the Murchison meteorite further documented the extraterrestrial origins of these compounds (Engel et al., 1990; Engel and Macko, 1997). The stable isotope approach continues to be used to document the occurrence of an extraterrestrial L-enantiomer excess of protein amino acids in other carbonaceous meteorites (e.g. Glavin et al., 2012). It has been suggested that this L-enantiomer excess may result from aqueous reprocessing on meteorite parent bodies (e.g. Engel, 2012; Glavin et al., 2012). Preliminary results of simulation experiments are presented that are used to determine the extent to which the stable isotope compositions of amino acid constituents of carbonaceous meteorites may have been altered by these types of diagenetic processes subsequent to synthesis.

9606-18, Session 7

Carbonaceous structures in the Tissint Martian Meteorite: evidence of a biogenetic origin *(Invited Paper)*

Jamie H. Wallis, Cardiff Univ. (United Kingdom); Nalin Chandra Wickramasinghe, Daryl H. Wallis, The Univ. of Buckingham (United Kingdom); Norimune Miyake, Chiba Institute of Technology (Japan); Max K. Wallis, The Univ. of Buckingham (United Kingdom); Richard B. Hoover, The Univ. of Buckingham (United Kingdom) and Athens State Univ. (United States)

We report for the first time in situ observations of 5-50μm spherical carbonaceous structures in the Tissint Martian meteorite comprising of pyrite (FeS2) cores and carbonaceous outer coatings. The structures are characterized as smooth immiscible spheres with curved boundaries occasionally following the contours of the pyrite inclusion. The structures bear striking resemblance to similar-sized immiscible carbonaceous spheres found in hydrothermal calcite vein deposits in the Mullaghwornia Quarry in central Ireland. Similar structures have been reported in Proterozoic and Ordovician sandstones from Canada as well as in a variety of astronomical sources including carbonaceous chondrites, chondritic IDPs and primitive chondritic meteorites. SEM and X-Ray elemental mapping confirmed the presence of organic carbon filling the crack and cleavage space in the pyroxene substrate, with further evidence of pyrite acting as an attractive substrate for the collection of organic matter. The detection of precipitated carbon collecting around pyrite grains is at variance with an igneous origin as proposed for the reduced organic component in Tissint, and is more consistent with a biogenetic origin.

9606-19, Session 7

Chemical and structural composition of organic carbonaceous structures in Tissint: evidence for a biogenetic origin

Jamie H. Wallis, Cardiff Univ. (United Kingdom); N. C. Wickramasinghe, Daryl H. Wallis, The Univ. of Buckingham (United Kingdom); Norimune Miyake, Chiba Institute of Technology (Japan); Max K. Wallis, The Univ. of Buckingham (United Kingdom); Richard Hoover, The Univ. of Buckingham (United Kingdom) and Athens State Univ. (United States)

Earlier studies of the Tissint Martian meteorite identified the presence of a number of 5-50μm carbonaceous spherical structures. SEM and EDS elemental spectra for 11 selected structures confirmed that they comprise of a carbonaceous outer coating with a inner core of FeS2 (pyrite) and are characterised as immiscible globules with curved boundaries. Here we report on the results of Raman spectroscopic studies that unambiguously confirm the mantle as comprising of 'disordered carbonaceous material'. R1 = ID/IG against ?D (cm-1) band parameter plots of the carbonaceous coatings imply a complex precursor carbon inventory comparable to the precursor carbon component of materials of known biotic source (plants, algae, fungi, crustaceans, prokaryotes). Correlation between peak metamorphic temperatures and Raman D-band (?D) parameters further indicate the carbonaceous component was subjected to a peak temperature of ~250 OC suggesting a possible link with the hydrothermal precipitation processes responsible for the formation of similar globules observed in hydrothermal calcite veins in central Ireland. ? G (cm-1), ?G (cm-1), ? D (cm-1) and ?D (cm-1) parameters further imply a level of crystallinity and disorder of the carbon component consistent with carbonaceous material recovered from a variety of non-terrestrial sources. Cl, N, O and S to C elemental ratios are typical of high volatility bituminous coals and distinctly higher than equivalent graphite standards.

9606-20, Session 7

Microbiological investigation of two chondrite meteorites: Murchison and Polonnaruwa

Elena V. Pikuta, Athens State Univ. (United States); Paul A. Lawson, Nisha Patel, The Univ. of Oklahoma (United States); William B. Whitman, The Univ. of Georgia (United States); Jacob Hagel, Daniel Easters, Geneviev LaBrake, Athens State Univ. (United States); Chandra N. Wickramasinghe, The Univ. of Buckingham (United Kingdom); Richard B. Hoover, Athens State Univ. (United States) and The Univ. of Buckingham (United Kingdom)

The problem of contamination of meteorites by modern environmental microorganisms is a serious issue that appears during interpretation of results of electron microscopy. Even so, the recently established marker

of nitrogen spectra (element spectrometry), which is low or absent in indigenous fossil material of a meteorite but significant in all modern contamination's cells, skepticism on the authenticity of these samples remains. Several investigations conducted by geologists found that environmental microorganisms could colonize the internal parts of meteorites with subsequent growth of Cyanobacteria being reported.

The purpose of this study is to demonstrate if any microbial contamination from the environment (geographical place where meteorites were found) would be present in the internal part of a meteorite. The possibility to metabolize organic matter of a meteorite as a major or supplemental substrate or growth factor by the bacteria from our laboratory culture collection will be checked. Potential toxic or inhibitory effects also will be tested on living cultures. UV exposure of the meteorites under investigation will be followed by the aseptic extraction of internal material that will be inoculated into growth media. All viable cells cultivated will be subjected to the study of physiology, molecular (16SrRNA sequencing) and microscopic investigation.

9606-21, Session 8

Instruments and methods to search for viable extraterrestrial microorganisms

Richard B. Hoover, The Univ. of Buckingham (United Kingdom) and Athens State Univ. (United States)

Is Life restricted to the Planet Earth? or Do living organisms exist today elsewhere in the Cosmos? The question of extant extraterrestrial life forms even more difficult and restrictive than the question of whether life forms that may have once inhabited the oceans of ancient Mars, comets, water-bearing asteroids or other cosmic bodies. During the past half century, microbiological studies have provided clear and convincing evidence that microbial extremophiles inhabit virtually every niche of planet Earth where water, energy, and a small suite of life-critical biogenic elements co-exist. No scientific rationale has ever been advanced to suggest that these essential requirements for life (as we know it) does not exist widely throughout the Universe. Furthermore, numerous independent studies have yielded a large body of imaging and spectral evidence for the remains of filamentous cyanobacteria and other prokaryotic and eukaryotic microorganisms in a variety of carbonaceous and SNC meteorites. Recent contamination is ruled out by the absence of detectable levels of nitrogen in the fossilized filaments. Recent contamination by living or dead modern terrestrial microbes is also excluded by the fact that the many independent meteoriticists who have studied these samples have failed to detect numerous essential life-critical biomolecules (unstable amino acids, nucleobases, ATP, chlorins, etc.) in the same meteorites (e.g., Orgueil, Murchison) that contain the fossils and are likely of cometary origin. The red, purple, green and blue-green regimes in high-resolution images of comet 67P/Churyumov-Gerasimenko are consistent with the phycoerythrin and phycocyanin photosynthetic pigments of cyanobacteria, and enhance the need for high resolution multi-spectral and fluorescence studies of these regions to search for biomolecular pigments.

The Viking Labeled Release Experiment results were consistent with metabolic activity possibly associated with viable microorganisms in the Mars regolith. However, the Viking results were dismissed on grounds that may have been erroneous. No life-detection experiment has been flown on any NASA Mars mission post-Viking. The confirmation of sporadic release of methane on Mars is consistent with possible metabolic activity of methanogenic archaea living today in the martian permafrost. It is now known that extremophiles can remain viable for thousands to millions of years while cryopreserved in ice and permafrost. This paper will discuss problems and consider some methods and instruments that may be used to remotely or directly obtain physical, chemical, biomolecular, or spectroscopic evidence for extant microorganisms on Mars, comets, water-bearing asteroids, or dwarf planets.

9606-23, Session 8

Raman laser spectrometer for ExoMars 2018 *(Invited Paper)*

Andoni G. Moral, Carlos Pérez Canora, INTA Instituto Nacional de Técnica Aeroespacial (Spain)

The Raman Laser Spectrometer (RLS) is one of the Pasteur Payload instruments, within the ESA's Aurora Exploration Programme, ExoMars mission.

ExoMars 2018 main Scientific objective is "Searching for evidence of past and present life on Mars".

Raman Spectroscopy is used to analyze the vibrational modes of a substance either in the solid, liquid or gas state. It relies on the inelastic scattering (Raman Scattering) of monochromatic light produced by atoms and molecules. The radiation-matter interaction results in the energy of the exciting photons to be shifted up or down. The shift in energy appears as a spectral distribution and therefore provides an unique fingerprint by which the substances can be identified and structurally analyzed.

The RLS is being developed by an European Consortium composed by Spanish, UK, French and German partners. It will perform Raman spectroscopy on crushed powdered samples, obtained from 2 meters depth under Mars surface, inside the Rover's Analytical Laboratory Drawer.

After a wide campaign for evaluating Instrument performances by means of simulation tools and development of an instrument prototype, Instrument Structural and Thermal Model has been successfully delivered on February 2015, and the Engineering and Qualification Model is expected to be manufactured by June 2015 for its delivery after a testing campaign by end of 2015.

A summary of main Instrument performances may be obtained during the following months, achieving high levels of spectral resolution and accuracy in the obtained spectra.

9606-24, Session 8

CRIRES+: the ESO/VLT planet hunter in the NIR

Ulf Seemann, Georg-August-Univ. Göttingen (Germany)

ESO's flagship high-resolution NIR spectrograph, CRIRES, is currently undergoing a major instrument upgrade. The project, through a consortium of five European institutions, transforms the latest of the first generation VLT instruments into "CRIRES+", adding capabilities such as cross-dispersion, polarimetry, large state-of-the-art detector mosaics, and a suite of new calibration techniques. CRIRES+ will be a premier instrument tailored for high-precision radial velocimetry on the sub-3m/s level, exoplanet athmosphere characterization, solar system studies and many others in the 1-5um domain at high spectral (R=1e5) and spacial (AO-assisted) resolution. CRIRES+ offers an observing efficiency boosted by more than an order of magnitude by its large simultaneous wavelength coverage, rendering it ideal for molecular spectroscopy.

In this talk, I will give an overview of the project and the lessons learned up to the current final design phase, and highlight the instrumental details as well as the performance related to the detection and characterization of (exo-)planets at first-light in 2017. A particular focus of the talk will be the set of calibration techniques, including a newly designed Fabry-Perot etalon system for reliable wavelength calibration of CRIRES+.

9606-26, Session 9

Terrain and biology of Comet 67P/ Churyumov–Gerasimenko *(Invited Paper)*

Chandra N. Wickramasinghe, The Univ. of Buckingham (United Kingdom) and Institute for the Study of Panspermia and Astroeconomics (Japan) and Univ.

of Peradeniya (Sri Lanka); Max K. Wallis, The Univ. of Buckingham (United Kingdom); Milton Wainwright, The Univ. of Sheffield (United Kingdom); G. Tokoro, Institute for the Study of Panspermia and Astroeconomics (Japan)

We examine a wide range of data from the Rosetta Mission all of which can be interpreted as pointing indirectly to microbiological activity in Comet 67P/Churyumov–Gerasimenko. The largest sea ('Cheops' Sea, 600 x 800m) curves around one lobe of the 4km-diameter comet, and the crater lakes extending to ~150m across are re-frozen bodies of water overlain with organic-rich sublimation lag of order 10 cm. The parallel furrows are seen that relate to flexing of a asymmetric and spinning two-lobe body, which generates fractures in an underlying body of ice. We draw attention to the existence of recently resealed cracks and fissures on smooth surface terrain as well as ongoing outgassing activity all of which are consistent with the presence of subsurface lakes. Within nutrient-rich watery domains biological activity builds up high pressures of volatile gases that sporadically leads to a rupturing of a frozen icy crust. The detection of a high abundance of complex organic molecules throughout the comet's surface by Philae combined with 3-D imaging of dust in the nm-?m size range from the MIDAS instrument aboard Rosetta also point to ongoing microbiology. The possibility of significant fluxes of nanometre-sized particles (of viral sizes) emanating from comets will be examined.

9606-27, Session 9

Big bang nucleosynthesis, comets and life

Robert B. Sheldon, NASA Marshall Space Flight Ctr. (United States)

The origin-of-life (OOL) consensus holds that life began 3.65-3.85Gya after Earth had cooled, or <100Mya since the molten Hadean. If true, OOL would populate planets multiple times de novo, but instead, every extraterrestrial fossil discovery is remarkably similar. We suggest comets not only are infected and transport life, but make up the ~70% dark matter of the galaxy, so that the entire galaxy is one connected biosphere ~12Gya. Although comets have all the right properties for dark matter, cosmologists argue that the Big Bang Nucleosynthesis (BBN) produces only hydrogen, helium and minute amounts of lithium. These BBN models, however, are 1-D, homogeneous, isotropic and without magnetic fields. In this paper we modify a state-of-the-art BBN model to include chaotic magnetic fields with a corresponding change to the equation of state. This not only creates Carbon-Oxygen to make primeval ice grains and comets that accelerate galaxy formation, but also the magnetized dust that may explain dark energy. We discuss how gamma-ray telescopes can observe the gravitational lensing of background light sources caused by this cometary fraction of dark matter. Thus the bioengineering of comets by life also affects cosmic evolution, providing a feedback from the very smallest to the very largest scales of the universe. In this sense, the universe is a coherent, low-entropy system designed for life.

9606-28, Session 9

Arrhenius reconsidered: astrophysical jets and the spread of spores

Malkah I. Sheldon, Covenant Christian Academy (United States); Robert B. Sheldon, NASA Marshall Space Flight Ctr. (United States)

In 1871, Lord Kelvin suggested that the fossil record could be an account of bacterial arrivals on comets. In 1903, Svante Arrhenius suggested that spores could be transported on stellar winds without comets. In 1984, Sir Fred Hoyle claimed to see the infrared signature of vast clouds of dried bacteria and diatoms. In 2012, the Polonnaruwa carbonaceous chondrite revealed fossilized diatoms apparently living on a comet. However, Arrhenius' spores were thought to perish in the long transit between stars. Those calculations, however, assume that maximum velocities are limited by solar winds to ~300 km/s. Herbig-Haro objects, however, are young stars with jets of near-relativistic speed, ~3000km/s. The central engine of astrophysical jets is not presently understood, but we argue it is a kinetic plasma instability of a charged central magnetic body. We show how to make a bipolar jet in a belljar. The instability is non-linear, and thus very robust to scaling laws that map from microquasars to active galactic nuclei. We scale up to stellar sizes and recalculate the viability/transit-time for spores carried by supersonic jets, to show the viability of the Arrhenius mechanism.

9606-29, Session 9

Hydro-gravitational-dynamics cosmology is crucial to astrobiology and the biological big bang at two million years

Carl H. Gibson, Univ. of California, San Diego (United States)

Collisional fluid mechanics and modern stratified turbulence theory is applied to the evolution of structures in self gravitational systems, starting with the cosmological big bang. Planck-Kerr turbulent combustion powers this event, producing a fireball quenched by gluon viscosity at 10^-27 seconds, and inflation. Fossils of big bang turbulence persist in the cosmic microwave background at scales > 10^25 meters. The baryon plasma fragments at galaxy scales at 10^12 s, producing weak turbulence. Earth mass gas planets in clumps of a trillion fragment at 10^13 s. Stars form by planet mergers, and explode. DNA life forms at two million years.

See journalofcosmology.com for details about HGD cosmology. HGD is crucial to understanding the formation of the 30,000,000 hydrogen planets that exist on average per star in all galaxies (not ~ 8 as usually assumed). These dark matter planets in clumps of a trillion have hosted life as we see it. All stars form by planet mergers within the dark matter clumps. If all planets in a clump merge to form stars, the clump is a globular star cluster. If the stars overfeed on planets, they explode to release carbon, oxygen and nitrogen as oxides. These are reduced to organic chemicals by the hydrogen to form water atmospheres of the hot planets (3000K). First iron, nickel and rocks condense to form planet cores. At 2 million years liquid water oceans condense. Organic chemistry evolves with the constant ocean mergers to form larger planets and stars, and RNA and DNA life as we know it is inevitable.

9606-30, Session 10

Link between organic life and hydrocarbons on comets and asteroids (eg. CCs): evolution of biogenic hydrocarbon source rocks and oil & gas on Mars, Earth, and other solar system planets (and their respective moons) *(Invited Paper)*

Prasanta K. Mukhopadhyay , Global Geoenergy Research Ltd. (Canada)

Previous data on various carbonaceous chondrites (CC) and comet dust by various scientists since the 1960s, recent findings on the abundance of hydrocarbon-like organic molecules in various moons of Saturn or Jupiter and comets (including the Comet 67P) and the key geological features and the abundance of methane on Mars may suggest the presence of abundant biologically derived thermogenic petroleum hydrocarbons within our Solar System . Recent geochemical and other analytical data of various CCs indicate that they are organic rich with abundant kerogens and oil like extractable biomarkers. They closely resemble terrestrial hydrocarbon source rock kerogen and bitumen usually observed in shale and carbonates on Earth. The bacteriomorphic microstructures preserved in these CCs closely resemble microbial (prokaryotic and archaeoprokaryotic) ecosystems established on Earth over 3.85 to 4 Ga years ago. The early geology of both planet Mars and Earth are quite similar. They both contain abundant water

and bacterial or algal derived organic components possibly suggesting a common link for the origin of life and the presence of hydrocarbons in planets (and their moons) within the Solar System. This data indicates that the hydrocarbon molecules that were originated from a organic life on CCs and Comets (as seen in Comet 67P) from a 'geopolymer'(PAHs like complex macromolecule) via a stage of "biopolymer" (bacterial and algal rich complex in mineral matrix). They were later transported in sediments to Mars, Earth, and other planets during the early formation of the Solar System along with the life forming elements and organic molecules.

Consequently, the Solar system possibly represents a connected biosphere with life transfer (originated in Comet and carbonaceous Asteroids) that has been continuously taking place on dynamic timescales for at least the last 4.5 Ga of years. Now the question before us is how life has been transported to various planets in the Solar System. It was suggested that life could be transported in the planets in the Solar System as a result of: (a) purging of the primordial "comet dust" or (b) slow impact of carbonaceous meteoritic showers. Both of them contain both life forming organic molecules and hydrocarbons. Life cannot have originated from a violent and high temperature impact by asteroid or comet.

9606-32, Session 10

Evidence of ancient microbial activity on Mars

Jamie H. Wallis, Cardiff Univ. (United Kingdom); N. C. Wickramasinghe, The Univ. of Buckingham (United Kingdom); Daryl Wallis, Cardiff Univ. (United Kingdom) and The Univ. of Buckingham (United Kingdom); Norimune Miyake, Chiba Institute of Technology (Japan); Max K. Wallis, The Univ. of Buckingham (United Kingdom); Richard B. Hoover, The Univ. of Buckingham (United Kingdom) and Athens State Univ. (United States)

We report for the first time in situ observations of a relatively rare secondary iron arsenate-sulphate mineral named bukovsk?ite – Fe3+2(As5+O4)(S6+O4)(OH)•7(H2O) - found in a shock melt vein of the Tissint Martian meteorite. It is hypothesised that the mineral formed when high concentrations of aqueous H+, Fe(III), SO4 and AsO4 were maintained for long periods of time in microenvironments created within wet subsurface Martian clays. The aqueous H+, Fe(III), SO4 and AsO4 species arose from the microbial oxidation of FeS2 with concurrent release of sequestrated As. The availability of aqueous AsO4 would also be complemented by dissolution by-products of the microbial reduction of Fe-oxides influenced by dissolved organic matter that alters the redox state and the complexation of As, thus shifting As partitioning in favour of the solute phase. This hypothesis is substantially supported by SEM analysis of a 15μm spherical structure comprising of a carbonaceous outer coating with a inner core of FeS2 (pyrite) that showed the pyrite surface with spherical pits, and chains of pits, with morphologies distinct from abiotic alteration features. The pits and channels have a clustered, geometric distribution, typical of microbial activity, and are closely comparable to biologically mediated microstructures created by Fe- and S-oxidising microbes in the laboratory. These microstructures are interpreted as trace fossils resulting from the attachment of bacteria to the pyrite surfaces.

9606-33, Session 11

Microorganisms in extreme environments with a view to astrobiology in the outer solar system *(Invited Paper)*

Joseph Seckbach, The Hebrew Univ. of Jerusalem (Israel); Julian Chela-Flores, The Abdus Salam International Ctr. for Theoretical Physics (Italy)

Life exists almost all over Earth environments. We are mainly familiar with the "normal" conditions where we find most of the living organisms. However, there are various prokaryotic microbes and a smaller number of eukaryotes that can tolerate and thrive in very severe places on Earth. These organisms that live at the edge of life are the extremophiles. Some of them are not able to tolerate the "normal" environments, while other "normal" organisms do not survive the extreme conditions.

Among the extremophiles are thermophiles thriving in high temperatures and psycrophiles in severe cold environments. In the ranges of pH are the acidophiles and the Alkaliphiles. The halophiles thrive in high solution of salt, a saline environment which can reach >30% dissolved salts. We know about prokaryotes and eukaryotes that flourish in niches with very low levels or absence of oxygen (anaerobes). Among the extremophiles, we also include those who tolerate dormancy and desiccation for long periods of time. Many extremophiles grow under more than a single stress factor; they are the Polyextremophiles.

A special discussion will be devoted to extremophiles and Astrobiology.

9606-34, Session 11

Molecular study of anaerobic strains from Antarctica and their taxonomic identifications

Zhe Lyu, William B. Whitman, The Univ. of Georgia (United States); Jacob Hagel, Daniel Easters, Geneviev LaBrake, Elena V. Pikuta, Athens State Univ. (United States)

Our previous study of phenotypic properties and 16SrRNA gene sequences demonstrated that two novel anaerobic strains from Antarctica have very close similarity with known species of the genera Halolactibacillus and Sanguibacter. To determine if these strains belong to separate novel species or differ just on a subspecies level, an additional molecular comparison was performed. Primers for a specific protein encoding genes were designed to conduct PCR amplification and sequencing. This method allows much higher resolution of the taxonomic affiliation than traditional sequencing the 16S rRNA gene.

Here we describe this molecular analysis with details regarding the PCR procedure, and the phylogenetic similarity of studied novel strains to the species (within Halolactibacillus and Sanguibacter genera) that were isolated from other continents.

9606-35, Session 11

Searching for the algorithm of genes distribution during the process of microbial evolution *(Invited Paper)*

Elena V. Pikuta, Athens State Univ. (United States)

Previous 2&3D graph analysis of Archaea and Bacteria demonstrated specific geometry in the function of a hyperboloid for physiological/environmental distribution of major microbial groups. Function of a two-sheet hyperboloid covered all known biological groups, and therefore, could be applied for the entire evolution of life on Earth. The vector of evolution was indicated from point of HyperthermophilyExtreme acidityLow salinity to the point of Low temperatureAlkalinityHigh salinity.

According to this vector, the following groups were chosen in the gene screening analysis: For the vector "High-Temperature ? Low-Temperature" within extreme acidic pH (0-3) Hyperthermophilic Crenarchaeota – order Sulfolobales, moderately thermophilic Euryarchaeota - Class Thermoplasmata, and mesophilic acidophiles- genus Thiobacillus and others. For the vector "Low pH ? High pH" the following groups of microorganisms were checked in three Temperature arias: a) Hyperthermophilic Archaea and Eubacteria; b) moderately thermophilic – representatives of the genera Anaerobacter and Anoxybacillus; and c) mesophilic haloalkaliphiles (Eubacteria and Archaea). The genes associated with acidophily (H+ pump), chemolitho-autotrophy (proteins of biochemichal cycles), polymerases, his tones were checked for the first vector, and for the second vector the genes associated with alkaliphily (K+/Na+ pumps), organotrophy (sugar- &

protein- metabolizing cycles), and others were screened.

Here, we present the results of tracing several evolutionary key genes associated with characters of physiological features of microorganisms. The search was performed by comparison of genome-draft sequences of representatives of major physiological groups of Archaea, Eubacteria, and Protozoa available in databases.

9606-36, Session 12

How can parasites promote life? Group behaviors and the 'Gangen' hypothesis *(Invited Paper)*

Luis Villarreal, Univ. of California, Irvine (United States)

Viruses are inherently dependent on others for replication so how can they be involved in the origin of life? Surely, cells must have evolved before virus. However, such dependency can also include other viruses, establishing some tendency for viruses to cooperate. Lytic viruses have long been thought to kill the most numerous host (i.e., kill the winner). But persisting viruses/defectives can also protect against viruses, especially in a ubiquitous virosphere. In 1991, Yarmolinsky et al. discovered the addiction modules of P1 phage, in which opposing toxic and protective functions stabilize viral persistence. Subsequently, I proposed that lytic and persisting cryptic virus also provide addiction modules that promote cooperation and group identity. In eukaryotes (and the RNA world), a distinct RNA virus–host relationship exists. Retrovirurses/retroposons are major contributors to eukaryotic genomes. Eukaryotic complexity appears to be mostly mediated by regulatory complexity involving noncoding retroposon-derived RNA. RNA viruses evolve via quasispecies, which contain cooperating, minority, and even opposing RNA types. Quasispecies can also demonstrate group preclusion (e.g., hepatitis C), thus quasispecies show both cooperation and group identity. Stem-loop RNA domains are found in long terminal repeats (and viral RNA) and are core mediators of viral regulation/identity. Thus, stem-loop RNAs may be ancestral regulators for all viruses. I here consider the RNA (ribozyme) world scenario from the perspective of addiction modules and cooperating RNA quasispecies (i.e., subfunctional agents that establish group identity). Such an RNA collective resembles a "gang" but requires the simultaneous emergence of endonuclease, ligase, cooperative catalysis, group identity, and history markers (RNA). I call such a collective a 'gangen' (pathway to gang) and suggest that a consortial group identity is needed for life to emerge.

9606-37, Session 12

Bioinformatics comparison of sulfate-reducing metabolism nucleotide sequences

George Tremberger Jr., Sunil Dehipawala, Andrew Nguyen, Todd Holden, David Lieberman, Tak D. Cheung, Queensborough Community College (United States)

Sulfate-reducing bacteria can be traced back to 3.5 billion years ago. The thermodynamics of the sulfur cycle has been well documented. A recent report with Genbank nucleotide data has been analyzed in terms of the sulfite reductase (dsrAB) needed its metabolism via fractal dimension and entropy and free energy values (Robator, Jungbluth, et al , 2015 Jan, Front. Microbiol) Archaea and bacteria 16S RNA has also been compared. The hypothesis of sulfate-reducing bacteria in the vicinity of organism that consume oxygen has been examined in terms of the metal requirement and competition, as a model for Sulfur Cycle (www.ncbi.nlm.nih.gov/pubmed/19426853) and photosynthesis adaptation in the Early Earth environment. Our results suggest that the clustering of the studied sequences in the Entropy-Fractal Dimension Diagram is consistent with an initial uniform distribution which then experienced a linear transformation indicative of a simple evolutionary pressure selection process. The sulfate-reducing bacteria in arctic (Robador, Brüchert, and Jørgensen, Environ Microbiol. 2009) and Psychrobacter metabolism nucleotide sequence difference is also discussed

9606-38, Session 12

Biological entities isolated from the stratosphere-evidence for a space origin

Milton Wainwright, Chandra N. Wickramasinghe, The Univ. of Buckingham (United Kingdom)

Since late 2013, we have reported scanning electron images (SEM) of biological entities (BEs) isolated from the stratosphere using a balloon-launched sampler. These reports provide evidence for a limited number, but wide variety of BEs which EDX analysis shows are not inorganic particles comprised of elements such as silicon, calcium and iron, but are instead comprise only carbon and oxygen, i.e. they have an organic composition. We suggest, based on the following, that these biological particles are incoming to Earth from space:

1) The BEs occur in very low numbers as isolated particles on the carbon sampling stubs which were exposed to the stratosphere. With the exception of a single diatom frustule fragment, known terrestrial organisms commonly found on Earth (e.g. grass seeds and pollen) are however, not sampled from this source. In addition material having the typical morphology and EDX signature of volcanic dust has never been seen on the sampling stubs.

2) The observed stratosphere–derived BEs is unusual and (with the exception of the diatom fragment) cannot be identified, by us, as terrestrial organisms (e.g. marine or terrestrial alga or protozoa).

3) The bimorphs are often associated with impact craters caused by inorganic, space-derived cosmic dust.

4) Some of the BEs themselves also produced impact craters on the carbon sampling stubs, again suggesting that they are incoming to Earth from space.

5) The BEs, and/or the inorganic masses on which they are found, exceed 5 microns, the size limit above which it is generally assumed that particles cannot be transported from the troposphere to the stratosphere. Finally we report evidence for the presence of biological entities comprised of nanoparticles which stain positive for DNA. We conclude that the biological entities we have isolated are continually arriving to Earth from space

9606-39, Session 12

Eukaryotes in oldest rocks of Earth and meteorites

Alexei Yu. Rozanov, Paleontological Institute (Russian Federation); Richard B. Hoover, Athens State Univ. (United States)

No Abstract Available

9606-40, Session 12

Phytoplankton and the Archean Earth system *(Invited Paper)*

Stanley M. Awramik, David J. Chapman, Univ. of California, Santa Barbara (United States)

The Archean Earth was significantly different from younger times. It was characterized by elevated surface temperatures (20oC to as much as 70oC), reduced solar luminosity, elevated CO2 and CH4 in the atmosphere, chemically insignificant atmospheric O2, UV radiation striking the surface, and an Earth spin rate almost double that of today. Hadley cells were probably more compact and severe, producing significant turbulence in the upper part of the water column. Higher surface temperatures could have resulted in increased salinity through evaporation and thus a higher density of seawater.

An unusual aspect of some Archean microfossils is their large size. Solitary, unicellular spindle or flanged-shaped microfossils from the ~3.4 Ga Strelley Pool Formation are up to 105 um in size and similar fossils in the

~3.3 Ga Kromberg Formation up to 135 um in size. The ~3.2 Ga Moodies Group contains spheroids up to 298 um in diameter. These large solitary microfossils are likely plankton, presumably phytoplankton. Such large size in pre-Phanerozoic microfossils is usually attributed to eukaryotes. However, eukaryotes did not arise until after the great oxidation event, 2.4 Ga. Thus, large size had some selective advantage in planktonic prokaryotes early in their history. But, were these vegetative cells, reproductive cells, or preserved envelopes containing many cells? The advantages for large size for prokaryotes in the Archean remain elusive but is probably tied to the Archean Earth system.

9607-1, Session 1

Measuring atmospheric carbon dioxide from space with the Orbiting Carbon Observatory-2 (OCO-2)

David Crisp, Jet Propulsion Lab. (United States)

Fossil fuel combustion, deforestation, and other human activities are now adding almost 40 billion tons of carbon dioxide (CO2) to the atmosphere each year. This is enough to increase the atmospheric CO2 abundance by more than 1% per year. Interestingly, as these emissions have increased over time, natural “sinks” in land biosphere and oceans have absorbed roughly half of this CO2, reducing the rate of atmospheric buildup by a factor of two. Measurements of the increasing acidity (pH) of seawater indicate that the ocean absorbs one quarter of this CO2. Another quarter is apparently being absorbed by the land biosphere, but the identity and location of these natural sinks are still unknown. The existing ground-based greenhouse gas monitoring network provides an accurate record of the atmospheric buildup, but still does not have the spatial resolution or coverage needed to identify or quantify CO2 sources and sinks. One way to address this need is to retrieve precise, spatially-resolved, global estimates of the column-averaged CO2 dry air mole fraction (XCO2) from space based measurements. The Orbiting Carbon Observatory-2 (OCO-2) is this first NASA satellite designed for this purpose. OCO-2 was launched from Vandenberg Air Force Base on 2 July 2014, and joined the 705 km Afternoon Constellation a month later. Its primary instrument, a 3-channel imaging grating spectrometer, was then cooled to its operating temperatures and began collecting about one million soundings over the sunlit hemisphere each day. This presentation will provide a brief overview of the preliminary results from this mission.

9607-2, Session 1

Toward consistent radiometric calibration of the NOAA AVHRR visible and near-infrared data record

Rajendra Bhatt, Science Systems and Applications, Inc. (United States); David R. Doelling, NASA Langley Research Ctr. (United States); Benjamin R. Scarino, Arun Gopalan, Conor O. Haney, Science Systems and Applications, Inc. (United States)

The 35-year Advanced Very High Resolution Radiometer (AVHRR) satellite-instrument data record is critical for studying decadal climate change, provided that the AVHRR sensors are consistently calibrated. Owing to the lack of onboard calibration capability, the AVHRR data need to be adjusted using vicarious approaches. One of the greatest challenges plaguing these vicarious calibration techniques, however, is the degrading orbits of the NOAA satellites that house the instruments, or, more specifically, the fact that the satellites eventually drift into a terminator orbit several years after launch. This paper presents a uniform sensor calibration approach for the AVHRR visible (VIS) and near-infrared (NIR) records using specifically designed NOAA-16 AVHRR-based, top-of-atmosphere (TOA) calibration models that take into account orbit degradation. These models are based on multiple invariant Earth targets, including Saharan deserts, polar ice scenes, and tropical deep-convective clouds. All invariant targets are referenced to the Aqua-MODIS Collection-6 calibration via transfer of the Aqua-MODIS calibration to NOAA-16 AVHRR using simultaneous nadir overpass (SNO) comparisons over the North Pole. A spectral band adjustment factor, based on SCanning Imaging Absorption SpectroMeter for Atmospheric CartograpHY (SCIAMACHY) spectral radiances, is used to account for the spectrally-induced biases caused by the spectral response function (SRF) differences of the AVHRR and MODIS sensors. Validation of the AVHRR Earth target calibration is performed by comparisons with contemporary MODIS SNOs. Calibration consistency between Earth targets validates the historical AVHRR record.

9607-3, Session 1

Geometric effects in SeaWiFs lunar observations

Robert E. Eplee Jr., Frederick S. Patt, Gerhard Meister, NASA Goddard Space Flight Ctr. (United States)

SeaWiFS made 204 lunar observatios over its 13-year mission. 145 radiometric trending observations were made at low phase angles (-8 to -6 degrees and +5 to +10 degrees). 59 additional observations were made at high phase angles (-26 to -49 degrees and +27 to +66 degrees). The NASA Ocean Biology Processing Group has undertaken a reanalysis of geometric effects in the SeaWiFS lunar data set with the final radiometric trend corrections applied. At high phase angles an increased uncertainty in the oversampling corrections of the lunar images gives rise to greater uncertainties in the lunar irradiances. Ratios of SeaWiFS observations to USGS ROLO photometric model predctions were fit with a quadratic function of phase angle and linear functions of sub-spacecraft point libration longitude and latitude angles. The phase and libration fit coefficients have been used as additional geometric corrections for the SeaWiFS lunar observations. For Band 1 (412 nm) and -50 degrees phase the phase correction is 1.8% and the libration correction is 0.7%. At +/- 7 degrees phase, the phase correction is 0.14% and the libration correction is 0.33%. At +50 degrees phase the phase correction is 0.3% and the libration correction is 0.7%. The long-term stability of the full data set is 0.058%, while the stability for the low phase angle data is 0.047%. These geometric corrections have reduced the overall scatter in the lunar observations, bringing the high phase angle data into family with the low phase angle measurements without impacting the time dependence of the low phase angle observations.

9607-4, Session 1

Cross radiometric calibration for GF-1 WFVs

Yong Xie, Institute of Remote Sensing and Digital Earth (China)

The Gaofen 1 (GF-1) satellite, the first satellite in Chinese high-resolution Earth Observation System (CHEOS), was launched successfully from Jiuquan Launch Centre on April 26, 2013. Except a 2m/8m Panchromatic Multi-spectral Sensor, a wide field of view (WFV) sensor is also installed on GF-1 platform, which is comprised of 4 cameras, namely WFV1, WFV2, WFV3, and WFV4, with the same nadir spatial resolution of 16m. The swath of each WFV camera is 200km and can reach to an 800km large swath by merging four cameras. Due to its high spatial resolution and wide swath, the GF-1 WFV image has been widely used in land and resources, agriculture, environmental protection, and surveying and mapping. In order to enhance the wideness and deepness of the quantitative remote sensing applications, it is crucial to implement the comprehensive post-launch calibration and validation to ensure the radiometric accuracy and consistency of GF-1 WFV cameras.

Since no on-board calibrator is equipped for GF-1 WFV, the cross-sensor radiometric calibration approach is one of effective ways to achieve the calibration coefficients. However, although the characteristics of four cameras are theoretically identical, the minute radiometric differences intrinsically exist. The separate radiometric calibration for each WFV camera is necessary. Furthermore, due to four WFV cameras are not independent and frequently used together, separate cross-sensor calibration with one reference sensor can cause large errors and cannot guarantee the consistency among cameras.

In this paper, we firstly plan to use the cross-sensor calibration method to achieve the accurate calibration coefficient for one of camera with the well-calibrated MODIS as the reference. After our statistical analysis, the amount of effective image pairs between WFV4 camera and MODIS over Dunhuang calibration site is the most, hence, WFV4 is chosen to perform the cross-sensor calibration to obtain the calibration coefficients. Secondly,

with the overlapping area between cameras, an inter-cross radiometric calibration method is proposed to carry out in-flight radiometric calibration for other WFV cameras with the reference of WFV4. Taken WFV3 and WFV4 camera as an example, the feasibility and precision of this method are performed. In this method, the correlation models of Digital Number and top of atmosphere radiances between WFV3 and WFV4 cameras are applied to implement the relative radiometric correction and get the absolute radiometric calibration coefficients of WFV3. Finally, the absolute radiometric calibration accuracy of the both cross-sensor and inter-cross calibration results and the radiometric inconsistency between cameras are validated

9607-5, Session 1

Preliminary evaluation of AHI L1b products

Xiangqian Wu, National Oceanic and Atmospheric Administration (United States); Hidehiko Murata, Japan Meteorological Agency (Japan); Fangfang Yu, ERT, Inc. (United States); Arata Okuyama, Japan Meteorological Agency (Japan); Michael Grotenhuis, ERT, Inc. (United States); Kotaro Bessho, Japan Meteorological Agency (Japan); Aaron Pearlman, Michael Chu, ERT, Inc. (United States)

The Advanced Himawari Imager (AHI) was successfully launched onboard Himawari-8 on October 7, 2014 for Japan Meteorological Agency (JMA). Level 1b (L1b) products have been generated from AHI since the first image on December 18, 2014. AHI is very similar to the Advanced Baseline Imager (ABI); both are of a new generation of geostationary imager developed by the U. S. for gathering environmental intelligence. ABI will be launched onboard GOES-R in 2016 for the U. S. National Oceanic and Atmospheric Administration (NOAA). NOAA and JMA are exchanging AHI data and the evaluation of its on-orbit performance. The data from and experience with AHI, 18 months before the ABI launch, provides a significant benefit in risk reduction for NOAA. We will present a preliminary evaluation of AHI L1b products. The exchange of information will enhance the usefulness of data from the JMA and NOAA systems for users worldwide.

9607-6, Session 1

Building vectorization inside a favela utilizing lidar spot elevation

Plinio Temba, Marcelo A. Nero, Lucas M. R. Botelho, Matheus E. C. Lopes, Univ. Federal de Minas Gerais (Brazil)

Brazil - officially the Federal Republic of Brazil, is the largest country in South America. It is the world's fifth largest country, both by geographical area and by population with over 192 million in habitant. Brazil is also home to a diversity of wildlife and extensive natural resources The Brazilian economy is the eighth largest by purchasing power parity. Despite the economic success, it is still a country with a high inequality rate wich is responsible for 25% of the big cities population living live in favelas (portuguese term for irregular settlements - IS). IS is a collection of shacks and poor quality housing system which often lack electricity or sewage disposal. Settlements Global Planning guides the local authorities for intervention in the IS and establishes priorities for implementing the actions and deeds. The diagnosis and proposals are analyzed in an integrated way through three lines of action: urban-environmental recovery; land regularization and development socio-organizational. This article describes the first stage to determining the SGP, which becomes the fisical property registry. The building registration process is determined with a developed algorithm in Matlab using the point cloud of the DSM and targets all points that lie on the roof of the building and the neighboring regions, then using models that analyze the operation of the laser sensor determines the centroid of the polygon. Furthermore, it discusses the advantages / disadvantages in terms of quality and runtime when compared with photogrammetric techniques.

9607-7, Session 1

Optimizing urban growth modeling based on land use/cover changes and road network by using agent-based cellular automata

Yousef Khajavigodellou, Salahaddin Univ.-Hawler (Iraq); Ali A. Alesheikh, K.N. Toosi Univ. of Technology (Iran, Islamic Republic of); Kamran Chapi, Univ. of Kurdistan (Iran, Islamic Republic of); Farshad Hakimpour, Univ. of Tehran (Iran, Islamic Republic of)

A city is considered as a complex system. It consists of numerous interactive sub-systems and is affected by diverse factors including governmental land policies, population growth, and transportation system. Urban modeling is a valuable tool for explaining mutual relation of the artificial and natural environment to help urban planners in complex situations. In this paper Patterns of Road Network, Type of Transportation systems and Land Use/ Cover Changes are considered as the three most important subsystems determining urban form and structure in the long term.

The CA – ABM model with spatiotemporal allocation criterions was shown effectiveness in simulation. Calibration of the Agent Base Cellular Automata model is one of the challenging issues in urban extension simulation. Complexity of urban development process, numerous variables, and various rules have made the calibration a difficult and sensitive stage within the modeling process. This paper presents a new version of CA and ABM models which parameterized for EMA and explores how factors such as road network, build-up area, green space, elevation, slope and types of transportation system can influence urban expansion.

CA model couldn't completely simulate the rules of agent, because after 2000s Erbil has shown rapid expansion based on agents. A few policy scenarios for baseline development, rapid development and green land protection under the influences of the behaviors and decision modes of regional authority agents, real estate developer agents, resident agents and future agents and their interactions must be apply to predict the future development patterns of the Erbil metropolitan region.

9607-8, Session 2

Design of an ultra-portable field transfer radiometer supporting automated vicarious calibration

Nikolaus J. Anderson, The Univ. of Arizona (United States); Kurtis Thome, NASA Goddard Space Flight Ctr. (United States); Jeffrey Czapla-Myers, Stuart Biggar, The Univ. of Arizona (United States)

The University of Arizona Remote Sensing Group (RSG) began outfitting the radiometric calibration test site (RadCaTS) at Railroad Valley Nevada in 2004 for automated vicarious calibration of Earth-observing sensors. RadCaTS was upgraded to use RSG custom 8-band ground viewing radiometers (GVRs) beginning in 2011 and currently four GVRs are deployed providing an average reflectance for the test site. This measurement of ground reflectance is the most critical component of vicarious calibration using the reflectance-based method. In order to ensure the quality of these measurements, RSG has been exploring more efficient and accurate methods of on-site calibration evaluation.

This work describes the design of, and initial results from, a small portable transfer radiometer for the purpose of GVR calibration validation on site. Prior to deployment, RSG uses high accuracy laboratory calibration methods in order to provide radiance calibrations with low uncertainties for each GVR. After deployment, a solar radiation based calibration has typically been used. The method is highly dependent on a clear, stable atmosphere, requires at least two people to perform, is time consuming in post processing, and is dependent on several large pieces of equipment. In order to provide more regular and more accurate calibration monitoring, the small

portable transfer radiometer is designed for quick, one-person operation and on-site field calibration comparison results. The radiometer is also suited for laboratory calibration use and thus could be used as the primary calibration standard for ground viewing radiometers of a RadCalNet site.

9607-9, Session 2

Atmospheric measurement analysis for the radiometric calibration test site (RadCaTS)

Jeffrey S. Czapla-Myers, The Univ. of Arizona (United States)

The Radiometric Calibration Test Site (RadCaTS) was developed by the University of Arizona in the early 2000s to collect ground-based data in support of the calibration and validation of Earth-observing sensors. It uses the reflectance-based approach, which requires measurements of the atmosphere and surface reflectance. These measurements are used in MODTRAN to determine the at-sensor radiance for a given time and date. In the traditional reflectance-based approach, on-site personnel use automated solar radiometers (ASR) to measure the atmospheric attenuation, but in the case of RadCaTS, and AERONET Cimel sun photometer is used to make atmospheric measurements. This work presents a comparison between the Cimel-derived atmospheric characteristics such as aerosol optical depth, the Angstrom exponent, and the columnar water vapor, to those derived using the traditional ASR. The top-of-atmosphere radiance derived using the Cimel and ASR are compared using Landsat 8 OLI for the period 2013–2014 to determine if any biases exist between the two methodologies.

9607-10, Session 2

Requirements for online resource for earth-observing satellite sensor calibration

Joel McCorkel, NASA Goddard Space Flight Ctr. (United States); Jeffrey S. Czapla-Myers, College of Optical Sciences, The Univ. of Arizona (United States); Brian Wenny, Science Systems and Applications, Inc. (United States); Kurtis J. Thome, NASA Goddard Space Flight Ctr. (United States)

The Radiometric Calibration Test Site (RadCaTS) at Railroad Valley Playa in Nevada is being developed by the University of Arizona to enable improved accuracy and consistency for satellite sensor calibration. Primary instrumentation at the site consists of ground-viewing radiometers, a sun photometer, and a meteorological station. Measurements made by these instruments are used to calculate surface reflectance, atmospheric properties and a prediction for top-of-atmosphere radiance. This work will leverage research for RadCaTS presented at this conference and describe the requirements for an online database, associated data formats and quality control, and processing levels.

9607-11, Session 2

Radiometric calibration of GLiHT's imaging spectrometer using GLAMR for satellite sensor intercalibration

Amit Angal, Science Systems and Applications, Inc. (United States); Joel McCorkel, NASA Goddard Space Flight Ctr. (United States)

NASA Goddard's Lidar, Hyperspectral and Thermal Imager (GLiHT) facilitates simultaneous measurements beneficial to variety of applications. Of the suite of "off-the shelf" instruments of GLiHT, the Visible Near-Infrared (VNIR) Imaging Spectrometer acquires high resolution spectral measurements (1.5 nm resolution) from 0.4 to 1 μm. Goddard Space Flight Center's Laser for Absolute Measurement of Response (GLAMR) was used to measure the absolute spectral response (ASR) of the GLiHT's imaging spectrometer. Continuously tunable lasers coupled to an integrating sphere allow a radiance-based calibration for the detectors at reflective solar wavelengths. GLAMR measurements, covering a wavelength range from 0.58 to 0.99 μm were acquired between July 30 to August 2, 2013. In order to account for the large field-of-view (50°), GLiHT was rotated in 2 degree increments so that the same area of the sphere is viewed by all detectors. Using this data along with the coincident Silicon trap radiometer measurements, the ASR was computed. The derived calibration parameters for GLiHT's Imaging Spectrometer are to be transferred to near-simultaneous measurements of Landsat sensors. Calibration uncertainty of GLiHT is 1-3% depending spectral region and transferring this traceability to coincident satellite sensors has 3-5% depending on spectral region.

9607-12, Session 3

Preliminary study for improving the VIIRS DNB low light calibration accuracy with ground based active light source

Changyong Cao, NOAA National Environmental Satellite, Data, and Information Service (United States); Yuqing Zong, National Institute of Standards and Technology (United States); Xi Shao, Yan Bai, Univ. of Maryland, College Park (United States)

There is a great interest in the science and user community in the Visible Infrared Imaging Radiometer Suite (VIIRS) Day/Night Band (DNB) low light detection capabilities at night for quantitative applications such as airglow, geophysical retrievals under lunar illumination, light power estimation, search and rescue, energy use, urban expansion and other human activities. This leads to a pressing need for improving the calibration stability and absolute accuracy of the DNB at low radiances. The low light calibration uncertainty was estimated to be at approximately 15% while the long-term stability has yet to be characterized. This study investigates the feasibility of accurate nightlight source at radiance levels near 3 nW?cm^?2?sr^?1, which potentially can be installed at selected sites for VIIRS DNB calibration/validation. Suomi NPP VIIRS observations from selected point sources are analyzed as examples. The illumination geometry, surrounding environment, as well as atmospheric effects are discussed. The uncertainties of the ground based light source are estimated. This study will contribute to the understanding of how the Earth's atmosphere and surface variability affect the stability of the DNB measured radiances; how to separate them from instrument calibration stability; whether or not SI traceable active light sources can be designed and installed at selected sites to monitor the calibration stability, radiometric and geolocation accuracy, and point spread functions of the DNB. Finally, it is also hoped to address whether or not active light sources can be used for detecting environmental changes, such as aerosols.

9607-13, Session 3

On-orbit calibration of S-NPP VIIRS day-night band and M bands using ground reference targets of Libya 4 and dome C sites

Xuexia Chen, Aisheng Wu, Science Systems and Applications, Inc. (United States); Xiaoxiong Xiong, NASA Goddard Space Flight Ctr. (United States)

This paper provides methodologies developed and implemented by the NASA VIIRS Calibration Support Team (VCST) to evaluate the S-NPP VIIRS Day-Night Band (DNB) on-orbit performance by monitoring the long term radiance and reflectance trends of DNB measurement over radiometrically stable ground sites. The DNB and M bands Sensor Data Records produced by the Interface Data Processing Segment (IDPS) and NASA Land Product Evaluation and Algorithm Testing Element (PEATE) are acquired nearly

nadir overpass for the Libya 4 desert and Dome C snow surfaces. The top of atmosphere radiance and reflectance long term trends are generated and the simulated DNB radiance values from the aggregated M bands (M4, M5, and M7) are compared with the simultaneously-observed DNB radiances. Our results show that since launch the DNB modulated RSR could have up to 4% influence on the DNB average solar spectral irradiances and the M bands influence have been less than 0.065%. After excluding some early mission data points, the results derived using IDPS DNB data show a general upward trend (about 10% - 16%) in both radiance and reflectance. These trends are likely caused by inconsistent calibration used in the IDPS forward data processing, including the use of different SDSM screen transmission and algorithms, and RSR degradation coefficients. On the other hand, the IDPS M4, M5, and M7 did not show obvious upward trends. By comparison, the long-term trends derived from the Land PEATE DNB and M bands data over Libya 4 and Dome C have been very stable.

9607-14, Session 3

Multiimage matching for lunar surface reconstruction from orbital images

Ahmed Elaksher, New Mexico State Univ. (United States)

The last three Apollo lunar missions (15, 16, and 17) carried an integrated photogrammetric mapping system of a Metric Camera (MC), a high-resolution Panoramic Camera, a Star Camera, and a Laser Altimeter. Recently images taken by the MC were scanned by Arizona State University (ASU); these images contain valuable information for scientific exploration, engineering analysis, and visualization of the moon's surface. In this article, we took advantage of the large overlaps, the multi viewing, and the high ground resolution of the images taken by the Apollo MC in generating an accurate and reliable surface of the moon. We started by computing the relative positions and orientations of the exposure stations through a rigorous photogrammetric bundle adjustment process. We then generated a surface model using a hierarchical correlation-based matching algorithm. The matching algorithm was implemented in a multi-photo scheme and permits the exclusion of obscured pixels. The generated surface model was registered with LOLA topographic data and the comparison between the two surfaces yielded an average absolute difference of 36 meters. These results look very promising and demonstrate the effectiveness of the proposed algorithm in accounting for depth discontinuities, occlusions, and noises.

9607-15, Session 3

Remote sensing of 'APEC blue' skies in China

Xingfa Gu, Ying Wang, Tianhai Cheng, Hao Chen, Hong Guo, Xiangqin Wei, Bin Li, Chinese Academy of Sciences (China)

Air pollution is more frequent and durative in China. During the Asia-Pacific Economic Cooperation summit (APEC) in early November, 2014, Beijing and adjacent provinces reduced pollutant emissions, yielding the 'APEC Blue' skies. As the visibility is largely concerned with the concentration of atmospheric aerosols (Dockery and Pope, 1996), we detected the Aerosol Optical Depth (AOD) using MODIS data during four periods - November 6-12, 2013, October 6-12, 2014, November 6-12, 2014 and December 6-12, 2014. We used lookup table method to retrieve AOD of 1 km resolution, during which MOD09 surface reflectance products were adopted and clustered aerosol models derived from AERONET measurements of Eastern Asia were used (Chen et al. 2013). Then we convert AOD values to PM2.5 concentration based on the linear relationship of ground-based PM2.5 measurements and AOD values. We found that: (1) the concentration of PM2.5 over Beijing in November 6-12, 2014 reduced by 47.8% compared with that in November 6-12, 2013; (2) the concentration of PM2.5 over Beijing-Tianjin-Hebei region in November 6-12, 2014 declined by 69.6% and 56.7% compared with that in October 6-12, 2014 and December 6-12, 2014; (3) the concentration of PM2.5 over Shandong province during APEC increased by 20.6% compared with that in 2013.

9607-16, Session 3

Cross calibration of GF-1 satellite PMS sensor using Landsat 8 OLI

Hailiang Gao, Institute of Remote Sensing and Digital Earth (China) and Chinese Academy of Sciences (China)

This paper presents the radiometric cross calibration of PMS sensor (Panchromatic and Multi-Spectral) aboard on Chinese GF-1 satellite using Landsat 8 OLI (Operational Land Imager). Two different SBAF factors (Spectral Band Adjustment Factor) were calculated using MODTRAN radiation transfer model, respectively. One is based on TOA radiance and the other is based on TOA reflectance. The cross calibration coefficients of these two SBAF factors are calculated and compared with office calibration coefficient. Then the uncertainty of cross calibration was analyzed. The results show that these two SBAF factor can be used for cross calibration.

9607-17, Session 4

Results from CrIS/ATMS obtained using an "AIRS version-6 like" retrieval algorithm

Joel Susskind, NASA Goddard Space Flight Ctr. (United States)

AIRS was launched on EOS Aqua in May 2002, together with AMSU-A to form a next generation polar orbiting infrared and microwave atmospheric sounding system. A main objective of AIRS/AMSU was to provide accurate unbiased sounding products with good spatial coverage that are used to generate stable multi-year climate data sets. AIRS/AMSU data for all time periods have been processed using the state of the art AIRS Science Team Version-6 retrieval methodology. The Suomi-NPP mission was launched in October 2011 as part of a sequence of LEO satellite missions under JPSS. NPP carries CrIS and ATMS, which are advanced infra-red and microwave atmospheric sounders that were designed as follow-ons to the AIRS and AMSU instruments. The objective of this work is to generate a long term climate data set of products derived from CrIS/ATMS to serve as a continuation of the AIRS/AMSU products. To achieve this, it is desirable for CrIS/ATMS to be processed using an algorithm similar to, or at least comparable with, AIRS Version-6. We have modified the AIRS Version-6 retrieval algorithm for use with CrIS/ATMS data and have been conducting research to optimize CrIS/ATMS products derived using this approach. As demonstrated on two different days in different seasons, CrIS/ATMS temperature and water vapor profiles retrievals are of very good quality, and are of comparable quality to and consistent with those retrieved from AIRS, as are other CrIS derived products. AIRS and CrIS products will be compared on daily, monthly mean, and interannual difference bases.

9607-18, Session 4

Comparison of AIRS and CrIS using synthetic principle component analysis

Hartmut H. Aumann, Evan M. Manning, Jet Propulsion Lab. (United States)

The algorithm used for the simulation of data is basically the forward algorithm used in the retrieval process. Inconsistencies between the observed data and simulated (expected) data can result in retrieval artifacts.

Synthetic Eigenvectors (SEV) are based on simulated data. Empirical Eigenvectors (EEV) are created from the data from the instrument. The residuals of data reconstruction from EEV show internal consistency, may be used to evaluate how many PC are needed to reproduce the data at the noise level and for noise filtering. They are not as useful for comparisons of two instruments. AIRS (grating array spectrometer) and CrIS (Fourier Spectrometer) respond different to spatial inhomogeneities due to the presence of clouds.

9607-19, Session 4

Improving AIRS radiance spectra in cloudy scenes using MODIS

Thomas S. Pagano, Hartmut H. Aumann, Denis A. Elliott, Evan M. Manning, Jet Propulsion Lab. (United States); Steven E Broberg, Jet Propulsion Lab (United States)

The Atmospheric Infrared Sounder (AIRS) on the EOS Aqua Spacecraft was launched on May 4, 2002. AIRS acquires hyperspectral infrared radiances in 2378 channels ranging in wavelength from 3.7-15.4 um with spectral resolution of better than 1200, and spatial resolution of 13.5 km with global daily coverage. The AIRS was designed to measure temperature and water vapor profiles for improvement in weather forecast and improved parameterization of climate processes. Currently the AIRS Level 1B Radiance Products are assimilated by NWP centers worldwide and have shown considerable forecast improvement. AIRS L1 and L2 products are widely used for studying critical climate processes related to water vapor feedback, atmospheric transport and cloud properties. AIRS trace gas products include ozone profiles, carbon monoxide, and mid-tropospheric carbon dioxide. The global daily coverage of AIRS allows scientists to follow the transport of these gases to aid in validation of chemical/weather transport models.

The AIRS radiances are calibrated using a uniform on-board blackbody and full aperture space view. For this reason, all radiometric measurements assume a uniform scene. As with most instruments, the AIRS 2D spatial response functions (tophat functions) are not flat for all channels, nor are they the same. When viewing a non-uniform scene, this causes a radiometric error that is scene dependent and cannot be removed without knowledge of the scene response. The magnitude of the error depends on the non-uniformity of the AIRS spatial response and the non-uniformity of the scene, but typically only affects about 1% of the data.

In this effort we use data from the MODIS instrument to provide information on the scene uniformity that can be used to correct the AIRS data. Early results show we can match the AIRS and MODIS radiances to about 0.6K when we include the AIRS tophat functions in the normalization of the MODIS data (Elliott, Proc SPIE 6296, 2006). The method requires use of different infrared bands in MODIS depending on the channels of AIRS being corrected. Resulting improvement in noise and bias will be presented by comparing to the new AIRS Level 1C product that uses PC techniques to correct impacted channels. The method can be used to recover impacted channels, validate the Level 1C product, and identify scene conditions where the error is most significant.

9607-20, Session 4

Enhanced simultaneous Nadir observations for IR sounder evaluation and comparison

Evan M. Manning, Hartmut H. Aumann, Jet Propulsion Lab. (United States)

Simultaneous Nadir Observations (SNO) contain thousands of pairs of observations taken within 8 km and 10 minutes. SNO have been very useful for comparisons in polar conditions. But SNO pairing criteria alone are not close enough in time and space for assessing small effects, like tropical cases with cloud, where the number of SNO is much more limited. We introduce a modified methodology, which finds pairs of matched spectra using looser spatio-temporal matching criteria but adding radiometric matching criteria. We illustrate this with AIRS and CrIS data. An AIRS FOV which is 45% cloudy will be matched to a CrIS FOV with a similar cloudiness, even though they are not the physically closest pair. Insight into instrument differences is gained from statistical distributions of the residual differences between the matched pairs. Sample analyses include comparisons of AIRS and CrIS spectra as function of cloudiness and comparisons of CrIS spectra from different FOVs. The proposed method may be applicable to matchups of other sensors on different spacecraft.

9607-21, Session 4

Usability, calibration, and data analysis issues in modern infrared spectrometers using large detector arrays

Denis A. Elliott, Hartmut H. Aumann, Jet Propulsion Lab. (United States)

Modern infrared spectrometers contain many detectors. The Moderate Resolution Imaging Spectrometer (MODIS) has 320 detectors. The Atmospheric Infrared Sounder (AIRS) has 4482 detectors. The Cross-track Infrared Sounder (CrIS) has only 27. This paper examines issues related to large arrays in multi-detector instruments and describes their impact on calibration and data analysis, using examples from AIRS and CrIS. Note that GIFTS was proposed with 2x256x256 channels and MISTIC is proposed with one 512x512 channel array. The potential differences among detectors are not limited to dead channels. They can include: noise characteristics, spatial response, illumination through the optical system, aging, and exposure to radiation. The more detectors in an instrument, the more important it is for both the hardware and data analysis software designers to be prepared to handle such differences. Techniques used on AIRS to mitigate these effects will be described.

9607-74, Session PMon

Intercomparison calibration study of Terra ASTER and MODIS

Karen Y. Yuan, Kurtis J. Thome, Joel McCorkel, NASA Goddard Space Flight Ctr. (United States)

Terra, the Earth-Observing System flagship, has reached a milestone with over 15 years of highly calibrated datasets. The value of these datasets will continue to grow and improve our understanding on the health of this planet. The present calibration study compares at sensor radiance between ASTER and MODIS with the latest calibration tables. Although ASTER and MODIS are on the same platform, they are not spectrally identical. To compensate this spectral difference, spectral correction is applied by using seasonal average from a hyperspectral sensor with 240 bands that cover from 420 - 2400 nm.

9607-75, Session PMon

Implementation of electronic crosstalk correction for terra MODIS PV LWIR bands

Xu Geng, Sriharsha Madhavan, Na Chen, Science Systems and Applications, Inc. (United States); Xiaoxiong J. Xiong, NASA Goddard Space Flight Ctr. (United States)

The MODerate-resolution Imaging Spectroradiometer (MODIS) is one of the primary instruments in the fleet of NASA's Earth Observing Systems (EOS) in space. Terra MODIS has completed 15 years of operation far exceeding its design lifetime of 6 years. The MODIS Level 1B (L1B) processing is the first in the process chain for deriving various higher level science products. These products are used mainly in understanding the geophysical changes occurring in the Earth's land, ocean, and atmosphere. The L1B code is designed to carefully calibrate the responses of all the detectors of the 36 spectral bands of MODIS and provide accurate L1B radiances (also

reflectances in the case of Reflective Solar Bands). To fulfill this purpose, Look Up Tables (LUTs), that contain calibration coefficients derived from both on-board calibrators and Earth-view characterized responses, are used in the L1B processing. In this paper, we present the implementation mechanism of the electronic crosstalk correction in the Photo Voltaic (PV) Long Wave InfraRed (LWIR) bands (Bands 27-30). The crosstalk correction involves two vital components. First, a crosstalk correction modular is implemented in the L1B code to correct the on-board Blackbody and Earth-view digital number (dn) responses using a linear correction model. Second, the correction coefficients, derived from the scheduled lunar observations, are supplied in the form of LUTs. Further, the LUTs contain time stamps reflecting to the change in the coefficients assessed using the Noise Equivalent difference Temperature (NEdT) trending. With the algorithms applied in the MODIS L1B processing it is demonstrated that these corrections indeed restore the radiometric balance for each of the affected bands and substantially reduce the striping noise in the processed images.

9607-76, Session PMon

Precise pre-launch radiometric calibration of VIIRS

Leonid A. Mikheenko, Volodymyr N. Borovytsky, Andrii V. Fesenko, National Technical Univ. of Ukraine (Ukraine)

The paper presents the new approach that includes technique, scheme and instruments for precise calibration of space-borne and airborne visible infrared imaging radiometers (VIIRs). The key component of this technique is the precise uniform light source based on optically- interconnected integrating spheres. Its principal advantages are high photometric and metrological characteristics. The light source contains several (5...11) primary integrating spheres of small diameters which are installed on a secondary integrating sphere of bigger diameter. The initial light sources – halogen lamps or light emitted diodes are installed inside the primary integrating spheres. These spheres are mounted on the secondary integrating sphere. The radiation comes from the primary integrating spheres to the secondary one through diaphragms which diameters can be varied. The secondary integrating sphere has an output aperture where uniform radiance emits. As a result the output radiance can be varied in extremely wide range – up to 600 W/(st•m2) with dynamic range 1 000 000 – without any change of spectral characteristics. Non-uniformity of the radiance throughout the output aperture can be small as 0.5 % because the secondary integrating sphere is illuminated uniformly and it does not contains lamps inside. The paper discusses the requirements to calibration system, the application of this light source in calibration procedures, metrological aspects of calibration and absolutization of measurements in radiometry.

9607-77, Session PMon

Assessment of scan-angle dependent bias of Suomi-NPP VIIRS day/night band from bridge light observations

Yan Bai, Univ. of Maryland, College Park (United States); Changyong Cao, National Oceanic and Atmospheric Administration (United States); Xi Shao, Univ. of Maryland, College Park (United States)

The low gain stage of the Visible Infrared Imaging Radiometer Suite (VIIRS) Day/Night Band (DNB) on Suomi National Polar-orbiting Partnership (NPP) is calibrated using an onboard solar diffuser. The calibration is then transferred to the medium and high gain stages of DNB based on the gain ratios determined from data collected in the solar terminator region. The calibration transfer causes increase of uncertainties and affects the accuracy of the low light radiances observed by DNB at night. Since there are 32 aggregation zones from nadir to the edge of the scan for DNB and each zone has its own calibration, the calibration versus scan angle of DNB needs to be independently assessed. This study presents preliminary analysis of the scan-angle dependence of the light intensity from lights at the San Mateo bridge observed by VIIRS DNB during 2014 in different aggregation zones. Cloud screening was done using VIIRS cloud masks. Effects of aggregation mode, aggregation mode dependent point spread functions, atmospheric path length, and potential traffic light at the time of observation, associated with scan angles are analyzed. The effect of lunar illumination is also taken into account based on model simulations. This study will be especially useful for JPSS J1 VIIRS, which is known to have a large nonlinearity across aggregation zones and new aggregation modes are being developed. The methodology developed will be very useful for the longterm vicarious monitoring the VIIRS/DNB performance and will be potentially useful for monitoring environmental changes such as aerosols.

9607-78, Session PMon

Noise characteristics research of Overhauser magnetometer sensor

Tala Liu, Lingjia Gu, Shuang Zhang, Haoyang Fu, Jilin Univ. (China)

Overhauser magnetometer, a kind of weak-magnetic measurement system based on the Overhauser effect, has been widely used in satellite magnetic survey, aeromagnetic survey and other engineering and environmental applications. Overhauser magnetometer plays an important role in the application of magnetic field measurement for its advantages of low power consumption and high accuracy. Weak field magnetic resonance is usually limited by the signal to noise ratio (SNR). In order to improve the SNR of Overhauser magnetometer, noise characteristics of Overhauser magnetometer sensor are researched in this paper. A background noise model of Overhauser magnetometer sensor is established. The calculated results indicate that the noise power spectrum destiny presents a band-limited white noise characteristic, and the maximum spectrum destiny observed at the resonant frequency is approximately equivalent to thermal noise of the matched resistance. The correlation between the SNR and the matched resistance is investigated by using the noise model. The calculated results demonstrate that large matched resistance is beneficial to improve the SNR of the sensor, although it generates more noise. When matched resistance is larger than 200k?, the SNR tends to be a constant. On the premise of ensuring proper bandwidth, the sensor will achieve the optimal SNR when the matched resistance is in the range of 80k?-100k?. The measured results coincide with the theoretical calculation, so the noise model is verified to be correct. This investigation is beneficial to improve noise performance of Overhauser magnetometer sensor.

An improved proton magnetometer for Earth's magnetic field observation

Chengyu Xiao, Shuang Zhang, Xin Guo, Haoyang Fu, Jilin Univ. (China)

As a precision instrument to measure the earth magnetic field, proton magnetometer is widely used on different fields such as geological survey, buried objects detection and earth field variations. Due to poor signal to noise ratio (SNR) of the system, proton magnetometer suffers from low sensitivity which directly affects the performance. In order to increase the sensitivity, we present an improved proton magnetometer. First, the effect of matching resistance on Q value is discussed to enhance SNR, and high matching resistance has been chosen to improve the Q value of the resonant circuit. Second, noise induced by pre-amplifier is investigated in order to obtain low noise signal, and we adopt the JFET with noise figure less than 0.5dB as the pre-amplifier. Third, by using band-pass filter, low-noise output signal is obtained. Fourth, the method of period measurement based on CPLD is employed to measure frequency of the square wave shaped from the output sinusoidal signal. High precision temperature compensate crystal oscillator (TCXO) has been used to improve the frequency measurement accuracy. Last, experimental data are obtained through field measurements. By calculating the standard deviation, the sensitivity of the improved proton magnetometer is 0.15nT for Earth's magnetic field observation. Experimental results show that the new magnetometer is sensitive to the earth field.

9607-81, Session PMon

GOCI in-orbit radiometric calibration status after four-year operation

Seongick Cho, Kibeom Ahn, Eunsong Oh, Korea Institute of Ocean Science & Technology (Korea, Republic of) and Yonsei Univ. (Korea, Republic of); YoungJe Park, Korea Institute of Ocean Science & Technology (Korea, Republic of); Sug-Whan Kim, Yonsei Univ. (Korea, Republic of)

The first spaceborne imager for ocean color remote sensing in Geostationary Earth Orbit (GEO), GOCI (Geostationary Ocean Color Imager)/COMS (Communication, Ocean and Meteorological Satellite), is successfully operated over the four years since its launch in June 2010. In order to fulfill the ocean color monitoring mission in geostationary orbit, GOCI implements 2D CMOS FPA (Focal Plane Array) with 2 million pixels, which enables staring capture method with 700km x 700km IFOV (Instantaneous Field of View) and 500m GSD (Ground Sampling Distance) over the center of the coverage area (130°E, 36°N) which corresponds to 380m GSD over the nadir. GOCI can observe Korea, Japan, and coastal region of China with 4 x 4 slot image acquisitions. One slot image of GOCI is equivalent to IFOV, and size of coverage area with 4 x 4 slot images is 2,500km x 2,500km including overlap area among adjacent slot images. GOCI equips 8 spectral bands. In visible wavelength region from 402nm to 685nm, 6 spectral bands are implemented on GOCI with the bandwidth of 20nm (for B1 ~B5) or 10nm (for B6, central wavelength at 680nm). Two spectral bands located in NIR wavelength region with band center at 745nm and 865nm are mainly used for the atmospheric correction.

In-orbit calibration method of GOCI is solar calibration using onboard Solar Diffuser (SD) and Diffuser Aging Monitoring Device (DAMD) equipped in the Shutter Wheel Assembly (SWA) on the top panel of the instrument. DAMD for the purpose of monitoring the in-orbit performance degradation of SD is identical to SD except for the size. The diameter of SD and DAMD are 14cm and 7cm, respectively. GOCI radiometric model which converts raw data recorded in DN (Digital Number) to physical unit (in the case of GOCI, it is radiance with the unit of W/m2/?m/sr) is defined with 3rd order polynomial with no quadratic term. Linear gain (G) and 3rd order non-linear gain (b) in GOCI radiometric model can be acquired from the calibration images observed with SD and DAMD at local night time. In this paper, we present the in-orbit radiometric calibration status of GOCI during first three years of operation. Annual sinusoidal variation of GOCI radiometric gains due to the diffuser transmittance variation with respect to the solar incident angle on azimuth direction is mainly discussed. Existing in-orbit calibration data shows that GOCI radiometric performance is stable with about 0.12% variation per year after the correction of annual diffuser variation in terms of solar incident angle.

Assessment of the collection 6 Terra and Aqua MODIS bands 1 and 2 calibration performance

Aisheng Wu, Xuexia Chen, Amit Angal, Yonghong Li, Science Systems and Applications, Inc. (United States); Xiaoxiong Xiong, NASA Goddard Space Flight Ctr. (United States)

MODIS (Moderate Resolution Imaging Spectroradiometer) is a key sensor aboard the Terra (EOS AM) and Aqua (EOS PM) satellites. MODIS collects data in 36 spectral bands and generates many data products for land, atmosphere, cryosphere and oceans. MODIS bands 1 and 2 have nadir spatial resolution of 250 m, compared with 500 m for bands 3 to 7 and 1000 m for all the remaining bands, and their measurements are crucial to derive key land surface products. This study evaluates the performance of the Collection-6 (C6) L1B calibrations of both Terra and Aqua MODIS bands 1 and 2 using three vicarious approaches. The first and second approaches focus on stability assessment using data collected from two pseudo-invariant sites on the Libya-4 desert and Antarctic Dome C snow surface over the entire mission. The third approach examines the relative stability between Terra and Aqua in reference to a third sensor from a series of NOAA 15-19 AVHRR (The Advanced Very High Resolution Radiometer). The comparison is based on measurements from MODIS and AVHRR Simultaneous Nadir Overpasses (SNO) over a thirteen-year period from 2002 to 2015. Results from this study provide a quantitative assessment of Terra and Aqua MODIS bands 1 and 2 calibration stability and the relative differences between the two sensors.

9607-83, Session PMon

Radiometric performance assessment of Suomi NPP VIIRS SWIR band (2.25 μm)

Sirish Uprety, Colorado State Univ. (United States); Changyong Cao, NOAA National Environmental Satellite, Data, and Information Service (United States)

Suomi NPP VIIRS SWIR band M11 (2.25 μm) has larger radiometric uncertainty compared to rest of the reflective solar bands. This could be due to a number of reasons including prelaunch calibration. One of the most commonly used technique of verifying the radiometric stability and accuracy of VIIRS is by intercomparing it with other well calibrated radiometers such as MODIS. One of the limitations of using MODIS is that VIIRS band M11 RSR doesn't overlap with MODIS bands at all. Thus the accuracy of intercomparison relies completely on how well the spectral differences are analyzed over the given target. Since desert sites have higher reflectance and more flat spectra, this study uses desert sites to analyze M11 radiometric performance. In order to better match the RSR between instruments, we have chosen Landsat-8 OLI SWIR band 2 (2.2 um) to perform intercomparison. This is mainly because OLI SWIR band 2 fully covers the VIIRS band M11 even though OLI has much wider RSR compared to VIIRS. The study suggests that there exists large radiometric inconsistency between VIIRS M11 and OLI, on the order of 5%. The impact due to spectral differences is estimated and accounted using EO-1 Hyperion observations and MODTRAN.

9607-84, Session PMon

Measured polarized transmittance of JPSS J1 VIIRS using the NIST T-SIRCUS

Jeffrey McIntire, Science Systems and Applications, Inc. (United States); James B. Young, Stellar Solutions Inc. (United States); David I. Moyer, The Aerospace Corp. (United States); Eugene Waluschka, Xiaoxiong J. Xiong, NASA Goddard Space Flight Ctr. (United States)

Recent pre-launch measurements performed on the Joint Polar Satellite System (JPSS) J1 Visible Infrared Imaging Radiometer Suite (VIIRS) using the NIST T-SIRCUS monochromatic source have provided wavelength dependent polarization sensitivity for select spectral bands and viewing conditions. Measurements were made at a number of input linear polarization states (thirteen in total) and initially over thirteen wavelengths. Using the source radiance information collected by an external monitor, a spectral responsivity function was constructed for each input linear polarization state. Additionally, an unpolarized spectral responsivity function was derived from these polarized measurements. An investigation of how the centroid, bandwidth, and detector responsivity vary with polarization state was weighted with a number of model input spectra to simulate both ground measurements as well as expected on-orbit conditions. These measurements will enhance our understanding of VIIRS polarization sensitivity, improve the design for future flight models, and provide valuable data to enhance products quality in the post-launch phase.

9607-85, Session PMon

Preliminary validation of Himawari-8/AHI navigation and calibration

Arata Okuyama, Akiyoshi Andou, Masaya Takahashi, Kenji Date, Tasuku Tabata, Keita Hosaka, Hidehiko Murata, Nobutaka Mori, Japan Meteorological Agency (Japan); Ryoko Yoshino, Japan Aerospace Exploration Agency (Japan); Kotaro Bessho, Japan Meteorological Agency (Japan)

The next-generation geostationary meteorological satellite of the Japan Meteorological Agency (JMA), Himawari-8, was successfully launched on 7 October 2014. The satellite will start operation in middle of 2015 after the completion of in-orbit testing and checking of the overall system. Himawari-8 features a new imager, Advanced Himawari Imager (AHI), with 16 bands. The imager's spatial resolution is double that of its predecessor satellites, MTSAT series. Full-disk imagery is obtained every 10 minutes. Rapid scanning with 2.5-minute interval is also conducted. These significant improvements will bring unprecedented levels of performance in nowcasting services and short-range weather forecasting systems. To bring out potential of the advanced imager sufficiently, precise navigation and accurate radiometric calibration are essential. This presentation will report navigation and calibration status of AHI.

Himawari-8 is equipped with three sensors onboard, the star tracker, the inertia reference unit and the angular rate sensor to realize accurate image navigation. The navigation and co-registration accuracy is validated by landmark analysis. As to radiometric calibration, AHI has a blackbody for infrared bands and a solar diffuser for visible and near infrared bands as on-board calibration references. We have a plan to perform inter-calibration and vicarious calibration in some approaches to improve its reliability. Our approach refers MTSAT observation, hyper-sounders observation such as AIRS, NPP/VIIRS observation, lunar model and simulated radiance by radiative transfer model. In the conference, the analysis based on pre-operational half year AHI data will be introduced.

9607-86, Session PMon

Comparison of JPSS-1 VIIRS VisNIR responsivities measured with monochromatic and broadband sources

Thomas Schwarting, Qiang Ji, Jeffrey McIntire, Hassan Oudrari, Science Systems and Applications, Inc. (United States); Xiaoxiong J. Xiong, NASA Goddard Space Flight Ctr. (United States)

NIST's laser-based traveling SIRCUS test facility was used to characterize the spectral response of the JPSS-1 VIIRS VisNIR bands after the conclusion of environmental testing in December 2014. The SIRCUS facility uses tunable lasers fed into an integrating sphere that is concurrently viewed by VIIRS and a calibrated reference detector which allows for a measurement of spectral response and the responsivity of the band through integrating the series of monochromatic measurements over the bandpass. Presented are the responsivities compared to those calculated via the traditional test method with a discussion of the impact of crosstalk to each measurement set.

9607-87, Session PMon

Extracting information on urban impervious surface from GF-1 data in Tianjin City of China

Bin Li, Institute of Remote Sensing and Digital Earth (China); Qingyan Meng, Jun Wu, Xingfa Gu, Chinese Academy of Sciences (China)

?1?Based on the spectral signatures of Tianjin's different surface features, Tianjin's surface coverage types can be divided in to 4 basic types, including vegetation, soil, high albedo and low albedo, and the linear model consisting of 4 endmembers selected by this study can well express the spectral signatures of Tianjin's different surface features. Then, solved by least square method without limited conditions of band correlations, coverage diagram of Tianjin's 4 endmember components was obtained. At last, after removing water body areas, impervious surface can be expressed as the overlay of high reflectance endmember coverage and low reflectance endmember coverage depending on the relationship among high albedo, low albedo and impervious surface. The estimation of Tianjin's impervious surface was verified by high resolution image data of remote sensing. In general, Tianjin has a relatively high impervious surface coverage, particularly Tianjin's central area and coastal area which have coverage of more than 65%.

?2?From the fig of Tianjin's impervious coverage, it can be found that the impervious coverage of Tianjin's coverage reaches up to 65%, while that the impervious coverage of Hongkong and some American cities is only 60% and 40% respectively. It is obvious that the overall ecological environment of Tianjin is poorer than Hongkong and some American cities, because of its high density of buildings and its small urban green space in its city system.

?3?When calculating the Tianjin's impervious surface coverage depending on linear spectral decomposition model, estimation accuracy is often influenced by water body shadow, spectral decomposition accuracy, high and low albedo. For example, the effect of removing water body will be influenced by the choice of method of water mask and the threshold value of binarization processing and low albedo of some areas will be increased by some shadow such as northwestern part of Wuqing District.

Vicarious validation of straylight correction for VIIRS day/night band using Dome-C

Shi Qiu, Xi Shao, Univ. of Maryland, College Park (United States); Changyong Cao, Wenhui Wang, NOAA National Environmental Satellite, Data, and Information Service (United States)

The Day/Night Band (DNB) of the Visible Infrared Imaging Radiometer Suite (VIIRS) onboard Suomi National Polar-orbiting Partnership (Suomi-NPP) represents a major advancement in night time imaging capabilities. However, the VIIRS DNB sensor is affected by stray light, which is due to solar illumination entering the optical path when the satellite passes through the day-night terminator at the spacecraft. The straylight results in an overall increase in the recorded radiance values. This effect is more significant during solstice. After launch of Suomi-NPP in October 2011 it was found that there is a gray haze in radiance images observed by DNB due to straylight and a straylight correction has been implemented to remove this effect. This study performs vicarious validation of straylight correction for VIIRS DNB band using Dome-C in Antarctic. Nadir observations of these high latitude regions by VIIRS are selected during perpetual night season, i.e. from April to July during the year 2014 under various lunar phases. The lunar spectral irradiance model, as a function of Sun-Earth-Moon distances and lunar phase, is used to determine the top-of atmosphere (TOA) reflectance at the vicarious site. The comparison of observed radiance and model predictions for different lunar phases are shown in this paper. In addition, the cross-comparison between DNB observations for events with/without straylight is also demonstrated. The VIIRS DNB data from two sources such as IDPS and NASA Land Peate are compared, which revealed some differences possibly due to difference in the calibration algorithm implementation.

Ray tracing based ISRD (inter-slot radiometric discrepancy) simulation tool for GOCI

Ki-Beom Ahn, Seongick Cho, Eunsong Oh, Korea Institute

of Ocean Science & Technology (Korea, Republic of) and Yonsei Univ. (Korea, Republic of); Young Je Park, Korea Institute of Ocean Science & Technology (Korea, Republic of); Sug-Whan Kim, Yonsei Univ. (Korea, Republic of)

Geostationary Ocean Color Imager (GOCI) is the world's first geostationary satellite for ocean color remote sensing mission. It observes coastal and ocean region around the Korean Peninsula, Japan, and East China with a spatial resolution of 500 meters.

GOCI uses step-stare imaging technique by the implementation of 2D detector array (1413 x 1430) and 2-axis pointing mechanism. It enables multiple image acquisitions for the same location of FOR (Field Of Regard) at sixty-minute intervals during daytime (8 images per day in nominal operation). Because GOCI IFOV is about a sixteenth of GOCI FOR, an image acquisition and processing sequence for GOCI FOR consists 16 (4 x 4) slot image acquisitions which correspond to GOCI IFOV and image processing to combine 16 slot images into one image for GOCI FOR.

Inter Solar Radiometric Discrepancy (ISRD) of GOCI means the radiance (i.e. digital count) discrepancy in the overlapped area between adjacent slot images. This is mainly derived by the difference of solar zenith angle by the gap of acquisition time between slots with overlapped area. Due to the boustrophedonic pattern of GOCI slot image acquisition sequence, maximum difference of acquisition time is about 12 minutes. After the normalization processing in terms of solar zenith angle for the reduction of ISRD, early in GOCI on-orbit operation, systematic residual ISRD about 3% discrepancy was observed for B6 (680nm) and B8 (865nm), where optical ghost/straylight in the southern part of a slot image was found to cause ISRD in the overlapped area between southern part of upper slot and northern part of lower slot.

For the qualitative and quantitative analyses of ISRD and the development of ISRD correction algorithm, end-to-end ISRD simulation tool based on ray tracing technique is developed. This also can be used for ISRD analysis of GOCI-II which is planned to be launched in late 2018. In this paper, we present the verification result of end-to-end ISRD simulation tool by comparing with pre-flight straylight/ghost test results, and development status of correction algorithm of systematic ISRD induced by straylight/ghost.

9607-90, Session PMon

How much particles outburst is responsible to Geomagnetism rise during SME of certain solar activity?

Umesh P Verma, Patna Science College (India); Sergy Pullinet, Academy of Russian academy,space science resdearch , (Russian Federation) and Spcae science research directorate (Russian Federation); Madhurendra Nath Sinha, Patna Science College (India)

X-ray flux fluctuation observant during particle outburst of most of common SME has been noticed through the GOES13-15 Satellite monitoring of NOAA and IPS Australia. In numerous instances X-ray have been observed to rise associated with the K index scaling 3to 6 level of D,C, and M class solar wind. Interaction of these cosmic particles consisting of electrons and protons and other radioactive particles have excited the ionospheres' environment resulting geomagnetism rise Facts are indicated by k index rise and scaling index reflective in the magneto gram recorded by Goes13 and 15 satellites link. Rise in x-ray flux are propitiating the proton flux and reciprocating electron flux on the site of observation of global map. Rise in geomagnetism is the consequent feature displayed by X-ray rise and other electromagnetic parameters fluctuation and variation. Our study notices interesting feature of k index rise of different class of solar mass ejection associating geomagnetism rise confusing about seismic activity at the site of observation. The doubt is clarified by D components of geomagnetism rise. X-ray observed by 13 and 15 have similar to some extent but differ in some respect.

9607-22, Session 5

Radiometric calibration and stability of the Landsat-8 operational land imager (OLI)

Brian L. Markham, NASA Goddard Space Flight Ctr. (United States); Julia A. Barsi, Edward Kaita, Lawrence Ong, Science Systems and Applications, Inc. (United States); Ron A. Morfitt, U.S. Geological Survey (United States); Md. Obaidul Haque, SGT, Inc. (United States); Jeffrey S. Czapla-Myers, College of Optical Sciences, The Univ. of Arizona (United States); Dennis L. Helder, Nischal Mishra, South Dakota State Univ. (United States)

Landsat-8 has been operating on on-orbit for two years with its two Earth imaging sensors: the Operational Land Imager (OLI) and the Thermal InfraRed Sensor (TIRS). This paper discusses the OLI, the reflective band instrument. The OLI has 9 spectral bands spanning from 443 nm to 2300 nm. The OLI has been extremely stable radiometrically since launch: the shortest wavelength band (443 nm) has degraded about 1% in responsivity over 2 years; all other bands have changed less than 0.3%. Multiple on-board calibration systems (3 lamps, 2 solar diffusers) as well as the moon and Earth targets are used at different revisit frequencies to aid in separating calibrator degradation from instrument degradation. The on-board and lunar techniques all show band average trends in responsivity consistent to within 0.3%, distinctly better than prior Landsat sensors. Comparisons to ground vicarious measurements and other sensors (MODIS Aqua, MODIS Terra, Landsat-7 ETM+) are generally within 5% for both reflectance and radiance.

9607-23, Session 5

OLI relative radiometric calibration

Julia A. Barsi, Brian L. Markham, NASA Goddard Space Flight Ctr. (United States)

The Operational Land Imager (OLI), on board the Landsat-8 satellite, is a pushbroom sensor with nearly 7000 detectors per band, divided between 14 separate arrays. While rigorously characterized prior to launch, the shear number of individual detectors presents a challenge to maintaining the relative calibration such that stripes, bands and other artifacts are minimized in the final image products.

On-orbit relative calibration of the OLI is primarily monitored and corrected using observations of the primary solar diffuser panel. The panel is the most uniform target available to the OLI. Just after launch, coefficients were derived to flat-field the solar diffuser data, both for individual detectors as well as across the 14 arrays. The discontinuities between arrays and the detector-to-detector uniformity continue to be monitored on a weekly basis.

Changes to the relative calibration since launch are thought to be changes in the calibration of individual detectors. Since launch the Coastal/Aerosol and Blue bands have shown the most change in relative calibration over time, with many detectors showing a slow drift of about 0.2% per year. However, larger changes have been seen in the SWIR bands, where individual detectors' responses change suddenly by as much as 1.5%.

The mechanisms behind these changes are not well understood but in order to minimize impact to the users, the OLI relative calibration is updated on a quarterly basis in order to capture changes in time.

9607-24, Session 5

Assessing OLI stray light and contamination changes with lunar observations

Raviv Levy, NASA Goddard Space Flight Ctr. (United States) and Science Systems and Applications, Inc. (United States); Philip W. Dabney, Brian L. Markham, NASA

Goddard Space Flight Ctr. (United States)

The Operational Land Imager (OLI) aboard the LDCM satellite was rigorously characterized prior to launch to assure stray light and ghosting artifacts are at an acceptable level for science needs. On orbit dedicated calibration collects are being made to continue monitor the OLI stray light performance. In this paper we report on the use of OLI on-orbit Lunar collects and subsequent processing that extracts and trends the stray light isolation level.

9607-25, Session 5

TIRS stray light correction: algorithms and performance

Aaron D. Gerace, Matthew Montanaro, Rochester Institute of Technology (United States); Julia A. Barsi, NASA Goddard Space Flight Ctr. (United States); Tim Beckmann, U.S. Geological Survey (United States); Victoria Scholl, Jiang Fu, Rochester Institute of Technology (United States)

The Thermal Infrared Sensor (TIRS) onboard Landsat 8 was tasked with continuing thermal band measurements of the Earth as part of the Landsat program. From first light in early 2013, there were obvious indications that stray light was contaminating the thermal image data collected from the instrument. Traditional calibration techniques did not perform adequately as non-uniform banding was evident in the corrected data and error in absolute estimates of temperature over trusted buoys sites varied seasonally and, in worst cases, exceeded 9 K error. The development of an operational technique to remove the effects of the stray light has become a high priority to enhance the utility of the TIRS data.

This paper introduces the current algorithm being tested by Landsat's calibration and validation team to remove stray light from TIRS image data. The integration of the algorithm into the EROS test system is discussed with strategies for operationalizing the method emphasized. Techniques for assessing the methodologies used are presented and potential refinements to the algorithm are suggested. Initial results indicate that the proposed algorithm significantly removes stray light artifacts from the image data. Specifically, visual and quantitative evidence suggests that the algorithm practically eliminates banding in the image data. Additionally, the seasonal variation in absolute errors is flattened and, in the worst case, errors of over 9 K are reduced to within 2 K. Future work focuses on refining the algorithm based on these findings and applying traditional calibration techniques to enhance the final image product.

9607-26, Session 5

Atmospheric correction for Landsat 8 over case 2 waters

Javier A. Concha, John R. Schott, Rochester Institute of Technology (United States)

Landsat 8 is a promising candidate to address the remote sensing of inland and coastal waters (Case 2 waters) due to its improved signal-to-noise ratio (SNR), spectral resolution, bit quantization, and high spatial resolution. Atmospheric correction is essential for remote sensing of water since the signal from the water reaching the sensor is small compared to atmospheric scattering. Standard atmospheric correction algorithms fail over highly turbid Case 2 waters because the black pixel assumption, i.e. the signal leaving the water is zero beyond near infrared (NIR), is not always satisfied. We develop a new atmospheric correction algorithm for Landsat 8 imagery based on the empirical line method (ELM) that does not rely on the black pixel assumption. This algorithm uses pseudo-invariant features (PIF) from the image, ground-truth data, and water-leaving reflectances from an in-water radiative transfer model to determine reflectance and radiance values of the bright and dark pixels used in the ELM method. We compare the results with in situ remote sensing reflectance measurements for different water bodies that exhibit a range of optical properties. We calculate reflectance errors for each band taking the in situ data as ground-truth, and then compare them to results from standard atmospheric correction algorithms.These reflectance errors are small in all the visible bands for a wide range of concentrations. These results show that our atmospheric correction algorithm allows one to use Landsat 8 to study Case 2 waters as an alternative to traditional ocean color satellites (e.g. MODIS, SeaWiFS).

9607-27, Session 5

Requirement sensitivity studies for a future Landsat sensor

Matthew Montanaro, Aaron D. Gerace, John R. Schott, Rochester Institute of Technology (United States); Brian L. Markham, NASA Goddard Space Flight Ctr. (United States)

The Landsat program has collected imagery of the Earth for the past 40 years. Although both Landsat 7 and 8 are currently operating on-orbit, the next generation Landsat mission is already being planned. Concept studies for this mission include reproducing the Landsat 8 design (mainly push-broom imaging architecture). The definition of science requirements is an important step towards the development of instrument specifications. At this early stage, a re-evaluation of the Landsat requirements is beneficial since they might be flexible enough to relax in some areas to possibly save on manufacturing costs or may need to be tightened in other areas to produce better science products. The investigations presented here focused on spatial aliasing and spectral banding effects. The specifications of these two key performance requirements were taken from the Landsat 8 Operational Land Imager (OLI) sensor as a starting point for the analyses. They were then adjusted to determine their effects on the final image products through the use of standard radiometry equations and synthetic Earth scene data. The results of the modeling efforts for these two requirements concepts are presented here and could be used as a template for future instrument studies.

9607-28, Session 6

Assessment of the clouds and the Earth's radiant energy system (CERES) instrument performance and stability on the Aqua, Terra, and S-NPP spacecraft

Nathaniel P. Smith, Susan Thomas, Mohan Shankar, Phillip C. Hess, Natividad M. Smith, Dale R. Walikainen, Robert S. Wilson, Science Systems and Applications, Inc. (United States); Kory J. Priestley, NASA Langley Research Ctr. (United States)

The Clouds and the Earth's Radiant Energy System (CERES) scanning radiometer is designed to measure reflected solar radiation and thermal radiation emitted by the Earth. Five CERES instruments are currently taking active measurements in-orbit with two aboard the Terra spacecraft (FM1 and FM2), two aboard the Aqua spacecraft (FM3 and FM4), and one aboard the S-NPP spacecraft (FM5). The CERES instrument uses three scanning thermistor bolometers to make broadband radiance measurements in the shortwave (0.3 – 5.0 micrometers), total (0.3 - >100 micrometers) and water vapor window (8 – 12 micrometer) regions. An internal calibration module (ICM) used for in-flight calibration is built into the CERES instrument package consisting of an anodized aluminum blackbody source for calibrating the total and window sensors, and a shortwave internal calibration source (SWICS) for the shortwave sensor. The ICM sources, along with a solar diffusor called the Mirror Attenuator Mosaic (MAM), are used to define shifts or drifts in the sensor response over the life of the mission. In addition, validation studies are conducted to understand any spectral changes that may occur with the sensors and assess the pointing accuracy of the instrument, allowing for corrections to be made to the radiance calculations in CERES data products. This paper covers the observed trends in the internal and solar calibration data, discusses the latest techniques used to correct for sensor response, and explains the validation studies used to assess the performance and stability of the instrument.

9607-29, Session 6

Evaluating the impact of cold focal plane temperature on Aqua MODIS thermal emissive photoconductive band calibration

Yonghong Li, Aisheng Wu, Brian Wenny, Science Systems and Applications, Inc. (United States); Xiaoxiong J. Xiong, NASA Goddard Space Flight Ctr. (United States)

Aqua MODIS, the second MODIS instrument of NASA Earth Observation System, has operated for over twelve years since launch in 2002. MODIS has sixteen thermal emissive bands (TEBs) located on two separate cold focal plane assemblies (CFPA). The TEB are calibrated using onboard blackbody and space view observations. MODIS CFPA temperature is controlled by a passive radiative cooler in order to maintain detector gain stability. Beginning in 2006, the CFPA temperature gradually varies from its designed operating temperature with increasing orbital and seasonal fluctuations. In Aqua Collection 6 (C6), a correction to the detector gain due to the CFPA temperature variation is applied for data after mid-2012, with the largest observed impacts on the TEB photoconductive (PC) bands. This paper evaluates the impact of the CFPA temperature variation on the TEB PC band calibration through comparisons with simultaneous nadir overpasses (SNO) measurements from the Infrared Atmospheric Sounding Interferometer (IASI) and Atmospheric Infrared Sounder (AIRS). Our analysis shows that the current L1B product from mid-2011 to mid-2012 is affected by the CFPA temperature fluctuation. The MODIS-IASI comparison results show that no drift is observed in PC bands over the CFPA temperature variation range, except band 33. In the MODIS-AIRS comparison, bands 31-32 show flat trends over the range of CFPA temperature while a slight drift in band 33 and relatively larger fluctuation in bands 34-36 are seen from the comparison results.

9607-30, Session 6

Electronic crosstalk in Terra MODIS thermal emissive bands

Junqiang Sun, National Oceanie and Atmospheric Administration (United States) and Global Science & Technology, Inc. (United States); Sriharsha Madhavan, Science Systems and Applications, Inc. (United States); Xiaoxiong Xiong, NASA Goddard Space Flight Ctr. (United States); Menghua Wang, NOAA National Environmental Satellite, Data, and Information Service (United States)

The MODerate-resolution Imaging Spectroradiometer (MODIS) is one of the primary instruments in the National Aeronautics and Space Administration (NASA) Earth Observing System (EOS). The first MODIS instrument was launched in December 1999 on board the Terra spacecraft. MODIS has 36 bands, among which bands 20-25 and bands 27-36 are thermal emissive bands covering a wavelength range from 3.7 ?m to 14.2 ?m. It has been found that there are severe contaminations in Terra bands 27-30 (6.7 μm – 9.73 μm) due to crosstalk of signals among them. The crosstalk effect induces strong striping in the earth view (EV) images and causes large long-term drift in the EV brightness temperature (BT) in these bands. An algorithm using a linear approximation derived from on-orbit lunar observations has been developed to correct the crosstalk effect for them. It was demonstrated that the crosstalk correction can substantially reduce the striping in the EV images and significantly remove the long-term drift in the EV BT in bands 27 and 28. In this paper, the crosstalk correction algorithm previously developed is applied to correct the crosstalk effect in bands 29 and 30. The crosstalk correction successfully reduces the striping in the EV images and removes long-term drifts in the EV BT in bands 29-30 as was done similarly for bands 27-28. The crosstalk correction algorithm can thus substantially improve both the image quality and the radiometric accuracy of the LWIR PV bands, bands 27-30, Level 1B (L1B) products. It is also shown that other Terra MODIS thermal emissive bands are contaminated by the crosstalk effect and that the algorithm can be applied to these bands for crosstalk correction.

9607-31, Session 6

Electronic crosstalk characterization of Terra MODIS long wave infrared channels

Sriharsha Madhavan, Science Systems and Applications, Inc. (United States); Xiaoxiong J. Xiong, NASA Goddard Space Flight Ctr. (United States); Junqiang Sun, Global Science & Technology, Inc. (United States) and National Oceanic and Atmospheric Administration (United States); Aisheng Wu, Science Systems and Applications, Inc. (United States)

Terra (T) MODerate-resolution Imaging Spectroradiometer (MODIS), a heritage Earth observing sensor has completed 15 years of operation as of December 18 2014. T-MODIS has 36 spectral channels designed to monitor the land, ocean, and atmosphere. The long term climate data record from T-MODIS is an important dataset for global change monitoring. Sixteen of the spectral channels fall in the Mid (M) (3.7-4.5μm) to Long (L) (6.7-14.1 μm) Wave InfraRed (M/LWIR) wavelengths, which are also referred to as the Thermal Emissive Bands (TEBs). To date the TEBs have very satisfactory performance which is attributed to the scan-by-scan calibration using an on-board BlackBody whose temperature is traceable to the NIST temperature standards. However, with an aging instrument, it was observed from 2010 onwards that the Photo Voltaic LWIR channels (Bands 27-30) have suffered significantly from electronic crosstalk. This is mainly due to the deterioration of the electronic circuits of the relevant bands in the LWIR Focal Plane Array (FPA). In this paper, we report the characterization of the electronic crosstalk in the above-mentioned bands using the scheduled sensor observations of the lunar surface, as well as from the Earth-view responses. Such characterization can be used to reduce the effects of crosstalk when implemented in the future Level 1B reprocessing and thereby increasing the radiometric fidelity of the concerned bands.

9607-32, Session 7

Solar diffusers in earth observation instruments with an illumination angle of up to 70°: design and verification of performance in BSDF

Bilgehan Gür, Hans Bol, TNO Science and Industry (Netherlands); Pengmei Xu, Bicen Li, Beijing Institute of Space Mechanics and Electricity (China)

An important part of an earth observation instrument is the onboard calibration unit. This unit ensures through its calibrating and monitoring functionality accurate performances and thus accurate scientific observations of an instrument during its lifetime in orbit. One critical optical element in this unit is the so-called solar diffuser, which is illuminated by the sun as an irradiance source. The diffusers performance is expressed through its scattering properties, the Bi-Directional Scattering

Function BSDF. The BSDF depends on several parameters, such as surface properties, angle of incidence and detection and further.

This paper describes the challenging diffuser design and verification activities of TNO under contract of a customer for an earth observation instrument with observation conditions that require feasible BSDF under large angles of incidence of up to 70° with respect to the surface normal.

Not only the design though but also the verification of the diffuser performance under such angles including “out-of-plane”, i.e. angle theta detection of the scattered light, was an essential activity to be executed. A representative measurement set-up was realized in the “Absolute Radiometric Calibration Facility ARCF” at TNO Delft in the Netherlands, a unique facility for the characterization and calibration of optical components for space applications.

In this paper we will summarize the R&D activities with respect to diffuser design and verification that were recently carried out at TNO and present its applicability to current and future earth observation missions with challenging observation conditions and thus challenging diffuser requirements under high illumination angles.

9607-33, Session 7

Characterization and application of a LED-driven integrating sphere source

Leibo Ding, Science Systems and Applications, Inc. (United States); Elena M. Georgieva, NASA Langley Research Ctr. (United States); James J. Butler, NASA Goddard Space Flight Ctr. (United States); Georgi T. Georgiev, John W. Cooper, Gilbert R. Smith, Science Systems and Applications, Inc. (United States)

A Light-Emitting Diode (LED)-driven integrating sphere light source has been fabricated and assembled in the NASA Goddard Space Flight Center (GSFC) Code 618 Biospheric Sciences Laboratory's Calibration Facility. This light source is a 30.5 cm diameter integrating sphere lined with Spectralon. A set of four LEDs of different wavelengths are mounted on the integrating sphere's wall ports. A National Institute of Standards and Technology (NIST) characterized Si detector is mounted on a port to provide real-time monitoring data for reference. The measurement results presented here include the short-term and long-term stability and polarization characterization of the output from this LED-driven integrating sphere light source. As part of its application, this light source is used to characterize detector/pre-amplifier gain linearity in light detection systems. The measurement results will be presented and discussed.

9607-34, Session 7

Improved thermal-vacuum compatible flat plate radiometric source for system-level testing of optical sensors

Mark A. Schwarz, Craig J. Kent, Stellar Solutions Inc. (United States); Steven W. Brown, National Institute of Standards and Technology (United States); Robert Bousquet, Genesis Engineering Solutions, Inc. (United States)

In this work, development of a fiber-optically coupled, vacuum-compatible, flat plate radiometric source applicable to the characterization and calibration of remote sensing optical sensors in situ in a thermal vacuum chamber is described. The original flat plate radiometric source configuration's performance was presented at the 2009 SPIE1. Following the original effort, design upgrades were incorporated in order to improve radiometric throughput and uniformity. Results of ambient and thermal-vacuum testing of a remote sensing optical sensor, with incorporated upgrades, of a flat plate illumination source are presented.

Keywords: Calibration, radiometry, remote sensing, source.

9607-35, Session 7

JPSS-1 VIIRS pre-launch radiometric performance

Hassan Oudrari, Jeff McIntire, Science Systems and Applications, Inc. (United States); Xiaoxiong Xiong, James Butler, NASA Goddard Space Flight Ctr. (United States); Boryana Efremova, Qiang Ji, Science Systems and Applications, Inc. (United States); Shihyan Lee, Contractor (United States); Tom Schwarting, Science Systems and Applications, Inc. (United States)

The Visible-Infrared Imaging Radiometer Suite (VIIRS) is a key instrument onboard the Joint Polar Satellite System (JPSS) spacecraft. The JPSS-1 (J1) mission is scheduled to launch in January 2017, and will be very similar to the Suomi-National Polar-orbiting Partnership (SNPP) mission. VIIRS instrument was designed to provide measurements of the globe twice daily. It is a wide-swath (3,040 km) cross-track scanning radiometer with spatial resolutions of 370 and 740 m at nadir for imaging and moderate bands, respectively. It has 22 spectral bands covering the spectrum between 0.412 μm and 12.01 μm, including 14 reflective solar bands (RSB), 7 thermal emissive bands (TEB), and 1 day-night band (DNB). VIIRS observations are used to generate 22 environmental data products (EDRs). This paper will briefly describe J1 VIIRS characterization and calibration performance and strategies executed during the pre-launch testing phases by the independent government team, to generate the at-launch baseline radiometric performance, and the metrics needed to populate the Look-Up-Tables (LUTs). This paper will also provide an assessment of the sensor pre-launch radiometric performance, such as the sensor signal to noise ratios (SNRs), dual gain transition verification, dynamic range, reflective and emissive bands calibration, bands spectral performance, response-vs-scan (RVS), and near-field-response. A comprehensive set of performance metrics generated during the pre-launch testing program will be compared to the SNPP VIIRS pre-launch performance.

9607-36, Session 7

JPSS-1 VIIRS pre-launch spectral characterization and performance

Christopher Moeller, Univ. of Wisconsin-Madison (United States); Thomas Schwarting, Jeffrey McIntire, Science Systems and Applications, Inc. (United States); Dave I. Moyer, The Aerospace Corp. (United States)

The pre-launch sensor level test program for the JPSS-1 VIIRS instrument, the second in the series (SNPP VIIRS launched in 2011), was completed in 2015 at the Raytheon El Segundo facility. The pre-launch test program provides characterization for all elements of sensor performance, populating the Sensor Data Record (SDR) algorithm lookup tables, and establishing compliance on performance metrics. During the pre-TVAC and TVAC phases, in-band and out-of-band measurements were collected to characterize the spectral performance of all VIIRS Moderate ("M"), Imager ("I") and Day-Night ("DNB") bands. The warm focal plane bands (M1-M7, I1, I2, DNB) were measured at ambient temperature using the Spectral Measurement Assembly (SpMA) with a tungsten source while the cold bands (M8-M16, I3-I5) were cooled to their nominal on-orbit operational temperature in a thermal vacuum environment and measured using a combination of the SpMA tungsten and heated ceramic element sources. A slit oriented along the length of the focal plane axis constrains the illumination to the 16 (32) detectors of an M-band (I-band) to prevent electrical or optical influences from other bands influencing the spectral characterization.

The spectral measurements have been analyzed by Raytheon analysts with oversight from subject matter experts (SME) on the VIIRS Data Analysis Working Group (DAWG), as well as independently analyzed by the DAWG spectral SMEs. The effort shows that all bands are well characterized, with minor non-compliances in a few bands similar to those seen on SNPP VIIRS. Significant non-compliant out-of-band response found in SNPP VIIRS warm focal plane bands has been largely eliminated by a redesign of the optical filters. Corrections for signal attenuation by absorbing gases in the ambient portion of the measurement environment are found to materially alter the RSR shape of two bands, M9 and M13. Comparisons of SNPP VIIRS RSR to those of JPSS-1 will be presented. The DAWG will be releasing JPSS-1 RSR products to the user community in the first quarter of 2015 with subsequent updates planned.

9607-37, Session 8

VIIRS/J1 Polarization Narrative

Eugene Waluschka, NASA Goddard Space Flight Ctr. (United States); Steven W. Brown, National Institute of Standards and Technology (United States); James J. Butler, NASA Goddard Space Flight Ctr. (United States); Eric C. Fest, Raytheon Missile Systems (United States); Keith R. Lykke, National Institute of Standards and Technology (United States); Brendan McAndrew, Joel McCorkel, NASA Goddard Space Flight Ctr. (United States); Jeffrey McIntire, Sigma Space Corp. (United States); Gerhard Meister, NASA Goddard Space Flight Ctr. (United States); Eslim O. Monroy, Raytheon Space and Airborne Systems (United States); David I. Moyer, The Aerospace Corp. (United States); Kevin Terpie, Kurtis J. Thome, NASA Goddard Space Flight Ctr. (United States); Tung R. Wang, Raytheon Space and Airborne Systems (United States); James B. Young, Stellar Solutions Inc. (United States)

The second Visible/Infrared Imager/Radiometer Suite (VIIRS) instrument, just as the first instrument, has a requirement that its polarization sensitivity not exceed 2.5% or 3% (depending on wavelength band). But, unlike the first instrument, the second instrument does exceed its requirement in four of its spectral bands. Needless to say, this was not welcome news which resulted in a careful look at the requirement and its uncertainty, at the polarization model and additional polarization measurements using broadband and monochromatic light. The following sections document the activities associated with the polarization model and the model results, the role of the focal plane filters, the polarization testing of VIIRS and its' Aft-Optic-Assembly, the testing of the polarizers, the use of NIST's T-SIRCUS for polarization testing and associated analyses.

9607-38, Session 8

Analysis of JPSS J1 VIIRS polarization sensitivity using the NIST T-SIRCUS

Jeffrey McIntire, Science Systems and Applications, Inc. (United States); James B. Young, Stellar Solutions Inc. (United States); David I. Moyer, The Aerospace Corp. (United States); Eugene Waluschka, NASA Goddard Space Flight Ctr. (United States); Hassan Oudrari, Science Systems and Applications, Inc. (United States); Xiaoxiong J. Xiong, NASA Goddard Space Flight Ctr. (United States)

The polarization sensitivity of the Joint Polar Satellite System (JPSS) J1 Visible Infrared Imaging Radiometer Suite (VIIRS) measured pre-launch using a broadband source was observed to be larger than expected for many reflective bands. Ray trace modeling predicted that the observed polarization sensitivity was the result of larger diattenuation at the edges of the focal plane filter spectral bandpass. Additional ground measurements were performed using a monochromatic source (the NIST T-SIRCUS) to input linearly polarized light at a number of wavelengths across the bandpass of two VIIRS spectral bands and two scan angles. This work describes the data processing, analysis, and results derived from the T-SIRCUS measurements, comparing them with broadband measurements. Results have shown that the observed degree of linear polarization, when weighted by the sensor's spectral response function, is generally larger on the edges and smaller in the center of the spectral bandpass, as predicted. However, particularly phase angle changes in the center of the bandpass differ between model and measurement. Integration of the monochromatic polarization sensitivity over wavelength produced results consistent with the broadband source measurements, for all cases considered.

9607-39, Session 8

Impacts of VIIRS polarization sensitivity on non-ocean scenes

Timothy S. Wilkinson, The Aerospace Corp. (United States)

The Visible and Infrared Imaging Radiometer Suite (VIIRS) collects Earth science data continually in a sun-synchronous orbit. VIIRS raw data records (RDRs) are processed by ground software to generate a variety of environmental data records (EDRs). Over open ocean, ground software produces measurements of chlorophyll concentration based on subsurface reflectance estimates. Considering that about 90% of the top of the atmosphere (TOA) radiance reaching a sensor over open ocean can be attributed to atmosphere or surface reflectance, it is possible to introduce large chlorophyll estimate errors by ignoring ordinarily small contributions due to polarization sensitivity. For chlorophyll determination, instrument polarization sensitivity measurements are used in combination with atmospheric models to compensate for polarization phenomenon. VIIRS ground software does not compensate for polarization phenomenon when processing land scenes. It is therefore natural to consider the impacts of ignoring VIIRS polarization phenomenon for land surface reflectance estimates. In this work, pre-flight polarization sensitivity characterization data is used in conjunction with a polarized atmospheric propagation model to analyze potential impacts on retrieved TOA reflectance. Impacts are analyzed across several collection conditions, including ground surface type, atmospheric visibility, general atmospheric profile and collection geometry. Actual pre-flight characterization data is used for both NPP and J1 VIIRS.

9607-40, Session 8

JPSS solar diffuser stability monitor response to sun angle of incidence

Vijay Murgai, Kristie Yu, Neil R. Nelson, Raytheon Space and Airborne Systems (United States); James K. McCarthy, Stellar Solutions Inc. (United States)

The Visible/Infrared Imaging Radiometer Suite (VIIRS) is a key sensor on the Suomi National Polar-orbiting Partnership (NPP) satellite in orbit as well as for the upcoming Joint Polar Satellite System (JPSS). VIIRS collects Earth radiometry and imagery in 22 spectral from 0.4 to 12.5 ?m. Radiometric calibration of the reflective bands in the 0.4 to 2.5 ?m wavelength range is performed by measuring the sunlight reflectance from Solar Diffuser Assembly (diffuser is Spectralon®). Spectralon® is known to solarize due to sun UV exposure at the blue end of the spectrum (~0.4 – 0.6+ ?m) as seen by laboratory tests as well as on orbit data from MODIS and NPP. VIIRS uses a Solar Diffuser Stability Monitor (SDSM) to monitor the change in the Solar Diffuser reflectance in the 0.4 – 0.94 ?m wavelength range to correct the calibration constants. The SDSM measures the ratio of sun light reflecting from the Solar Diffuser to a direct view of the sun. As the intensity of the light reaching the SDSM in both Solar Diffuser view and sun view is a function of the sun's angle of incidence (AOI), the SDSM response to sun AOI has to be characterized.

This paper presents details of the test setup including an extended collimated source simulating the sun across all SDSM bands. The pre-launch characterization results for the J1 SDSM are presented. Comparison with NPP on orbit yaw maneuver SDSM results shows similar behavior demonstrating that the J1 test successfully characterized the SDSM response to sun AOI.

9607-41, Session 9

JPSS-1 VIIRS pre-launch day/night band radiometric calibration

Thomas Schwarting, Science Systems and Applications, Inc. (United States); ShihYan Lee, ERT, Inc. (United States); Jeffrey McIntire, Science Systems and Applications, Inc.

(United States); Xiaoxiong J. Xiong, NASA Goddard Space Flight Ctr. (United States)

JPSS-1 VIIRS, like its predecessor SNPP-VIIRS, features the panchromatic, three gain stage, Day/Night Band (DNB) capable of imaging the Earth under illumination conditions ranging from direct sunlight to reflected moonlight. The DNB CCDs use 32 different modes of time-delay integration and sub-pixel aggregation to achieve high SNR in low light conditions whilst maintaining roughly constant spatial resolution across scan. In the pre-launch test program these 32 different aggregation modes are separately calibrated over a dynamic range covering 7 orders of magnitude through a series of tests designed to generate initial calibration coefficients for the Sensor Data Record (SDR) algorithm lookup tables, assess radiometric performance, and determine compliance with the sensor specification.

Early in environmental testing at Raytheon El Segundo non-linear behavior was discovered in the DNB aggregation modes used at the end of scan for low signal levels. In response to this non-linearity, which was not present in SNPP VIIRS, the test program was modified to characterize the radiometric performance both in the baseline configuration and with a modified aggregation scheme that eliminates the modes used at the end of scan, replacing them with the unaffected adjacent mode and trading off spatial resolution for improved linearity. Presented is the radiometric performance under both sensor configurations including dynamic range, sensitivity, radiometric uncertainty and non-linearity along with a discussion of the potential impacts to on-orbit calibration and SDR performance.

9607-42, Session 9

JPSS-1 VIIRS DNB/SWIR non-linearity and its impact on SDR calibration

ShihYan Lee, Wenhui Wang, ERT, Inc. (United States); Chengyong Cao, NOAA National Environmental Satellite, Data, and Information Service (United States)

During JPSS-1 VIIRS testing at Raytheon El Segundo, non-linear behaviors were discovered in the low radiance levels of the SWIR band and DNB. In addition, the DNB non-linearity is aggregation mode dependent, where the most severe non-linear behavior are the aggregation modes used at high scan angles (>49 degree). A modified test program was conducted to characterize this non-linear behavior. Based on the characterized non-linear behavior, we explored options in modified on-orbit calibration strategy to improve SDR accuracy in the non-linear regions. The potential performance improvement of the modified calibration strategy is analyzed and compared with the baseline (NPP) calibration strategy. The options in SDR code and Look Up Tables (LUTs) modifications are also presented with a discussion of calibration efficiency and on-orbit operation.

9607-43, Session 9

Preliminary results of J1 VIIRS ground geometric testing

Guoqing Lin, Science Systems and Applications, Inc. (United States); Robert E. Wolfe, NASA Goddard Space Flight Ctr. (United States); Masahiro Nishihama, Science Systems and Applications, Inc. (United States)

Following the successful operations of the first Visible Infrared Imaging Radiometer Suite (VIIRS) instrument on-board the Suomi National Polar?orbiting Partnership (SNPP) spacecraft since launch in October 2011, a second VIIRS instrument to be on-board the first Joint Polar Satellite System (JPSS-1) satellite has been fabricated. Ground testing at the sensor level has been completed in December 2014, which included geometric functional performance testing. The instrument geometric performance includes sensor (detector) spatial response, band-to-band co-registration (BBR) and pointing stability. They parameters have been calibrated and characterized through ground testing under ambient and thermal vacuum conditions, and numerical modeling and analysis. This paper summarizes the preliminary results, along with anomaly investigations. VIIRS sensor spatial response is measured by line spread functions (LSFs) in the scan and track directions for every detector. We parameterize the LSFs by: 1) dynamic field of view (DFOV) in the scan direction and instantaneous FOV (IFOV) in the track direction; and 2) modulation transfer function (MTF) for the 17 moderate resolution bands (M-bands) and for the five imagery bands (I-bands). We define VIIRS BBR for M-bands and I-bands as the overlapped fractional area of angular pixel sizes from the corresponding detectors in a band pair, including nested I-bands with M-bands. The ground tests result in static BBR matrices. VIIRS pointing stability includes scan plane tilt, scan rate and scan start position variations, and thermally induced pointing variations with respect to orbital position. These will be tracked or corrected in on-orbit operations.

9607-44, Session 9

A robust method for determining VIIRS calibration coefficients in solar reflective bands

Qiang Ji, Boryana V. Efremova, Thomas Schwarting, Jeffrey McIntire, Hassan Oudrari, Science Systems and Applications, Inc. (United States); Xiaoxiong J. Xiong, NASA Goddard Space Flight Ctr. (United States)

This paper presents a method for determining the JPSS J1 VIIRS RSB calibration coefficients and their uncertainties in quadratic calibration equation. Similar to a historical “attenuator method,” our method is based on all measurements with and without an attenuator deployed. Different from other polynomial curve fitting techniques, which fit multiple coefficients in a complex nonlinear equation, our method breaks the fitting into two parts. The first part is a quadratic equation for the transmittance of attenuator, which can be solved analytically on four sets of measurements. The second part is a reformed calibration equation, which is linear for the zeroth-order to first-order and the second-order to first-order coefficient ratios once the transmittance is known. For both parts a non-parametric technique (Theil-Sen estimator) yields robust solutions using all combinations of measurements. After the two coefficient ratios are determined, the first-order coefficient is given in the calibration equation. In short, our method is numerically stable, and the analysis of uncertainty is straightforward. To demonstrate the results, examples using the recent JPSS J1 VIIRS pre-launch tests data are shown.

9607-45, Session 9

Modeling spectrally varying resolution in broadband imaging systems

Stephen A. Cota, Scott L. Schnee, Adam L. Loverro, The Aerospace Corp. (United States)

No Abstract Available

9607-46, Session 9

Simple techniques for modeling wavefront error in imaging systems

Scott L. Schnee, Stephen A. Cota, The Aerospace Corp. (United States)

No Abstract Available

9607-47, Session 10

Demonstrating the error budget for the climate absolute radiance and refractivity observatory through solar irradiance measurements

Kurtis J. Thome, Joel McCorkel, Brendan McAndrew, NASA Goddard Space Flight Ctr. (United States)

The Climate Absolute Radiance and Refractivity Observatory (CLARREO) mission addresses the need to observe high-accuracy, long-term climate change trends and to use decadal change observations as a method to determine the accuracy of climate change. A CLARREO objective is to improve the accuracy of SI-traceable, absolute calibration at infrared and reflected solar wavelengths to reach on-orbit accuracies required to allow climate change observations to survive data gaps and observe climate change at the limit of natural variability. Such an effort will also demonstrate NIST approaches for use in future spaceborne instruments.

9607-48, Session 10

Development of the next geostationary ocean color imager, GOCI-II

Seongick Cho, YoungJe Park, Kibeom Ahn, Eunsong Oh, Yu-Hwan Ahn, Korea Institute of Ocean Science & Technology (Korea, Republic of)

After the successful launch and operation of Geostationary Ocean Color Imager (GOCI), the first pathfinder of ocean color remote sensing in geostationary orbit from 2010, necessity of succession of GOCI mission after the expected lifetime by 2018, is gradually increasing into the international ocean color remote sensing users as well as domestic users in Korea.

As a successor of GOCI, development of GOCI-II has been started in 2012 with a planned launch in 2018. The mission and user requirements of GOCI-II are defined by Korea Institute of Ocean Science and Technology (KIOST) and international GOCI PI (Principal Investigators). GOCI-II will be able to monitor the nearly full Earth disk area on 128.2°E longitude in geostationary orbit, and to acquire the local area(observation region can be freely definable by user) image with 250m spatial resolution at nadir with 12 spectral bands from visible to NIR (370~885nm). These enhanced features will enable the monitoring and research of long-term ocean environment change with better image quality. Additional 4 spectral bands are added to improve the accuracy of data products such as chlorophyll concentration, total suspended sediments, dissolved organic matters, enhancement of atmospheric correction, and to have a novel capability such as PFT (Phytoplankton Functional Type) which enables to discriminate harmful algae bloom. Newly implemented panchromatic band with 402~885nm bandwidth is expected to enable star imaging for the geometric correction of GOCI-II images.

Full Disk(FD) and user-definable local area observation mode to be implemented for GOCI-II will satisfy the user requests such as ocean observation over clear sky without clouds and special ocean event area over specific region in anytime and anywhere. We are expecting this new capability will produce more applicable data products about special event area such as typhoon, oil spill, green algae bloom, and etc. GOCI- II will perform 10 LA observations per day. This is two more LA observations per day than the number of daily LA observations of GOCI (8 times per day). Additionally, a daily global observation is planned for GOCI-II for the research of long-term climate change in ocean.

In order to develop the GOCI-II with the full satisfaction of user requirements and to develop the data processing technique based on the actual GOCI-II on-ground test results, two research scientists are working together as Joint Development Team (JDT) with Airbus Defence & Space, and KARI (Korea Aerospace Research Institute). Airbus DS is the GOCI-II main developer according to the contract signed in July 2013. In this workshop, we present the development status of GOCI-II and principal enhancement of GOCI-II comparing with GOCI.

9607-49, Session 10

New polishable R-SiC layer on ultra lightweighted SiC substrates for space applications

Eric Ruch, REOSC (France)

Silicon Carbide is a material of high interest in the design and manufacturing of space telescopes, thanks to its mechanical and thermal properties.

Reosc has manufactured the 3 TMAs of the NIRSpec instrument that will take place on board JWST. Reosc has also polished 2 sets of mirrors for the Japanese HISUI instruments. Reosc has also polished the 1.5m primary mirrors of the GAIA instrument and currently polishing the scan mirrors of the MTG telescope and the 1,3m diameter primary mirror of the EUCLID instrument.

Based on this experience, Reosc is still improving its capability in the field of SiC mirrors. Two main activities are currently on-going:

1. replacement of CVD SiC by a new polishable layer R-SiC

2. development of ultra-lightweighted SiC mirror

The polishing of usual SiC mirrors does not provide very low micro-roughness. The current process uses CVD SiC that has some drawbacks, mainly in terms of sizability to very large mirrors. This is why Reosc has developed an alternative material for polishing layers, R-SiC. The main requirements (low micro-roughness polishing, CTE compatibility with substrate, environment compatibility) have been successfully demonstrated. The next phase of the technology research program run in collaboration with ESA was to manufacture a 300mm demonstrator.

Reosc has successfully polished two ultra-lightweighted SiC mirrors, with R-SiC polishable layer, with an areal density of 20kg/m?. The design and the manufacturing process are representative of a 1.5 to 2m diameter mirror class. The goal is to develop the process and the tools allowing the polishing of this mirror including the quilting conditions.

9607-50, Session 10

Novel compound parabolic concentrator for broadband radiometric measurement of ratio of reflected to incoming solar radiations around L1 halo orbit

Sehyun Seong, Sug-Whan Kim, Yonsei Univ. (Korea, Republic of); Michael Lockwood, The Univ. of Reading (United Kingdom)

The broadband scanning radiometer concept using compound parabolic concentrator (CPC) was proposed for measurement of ratio of reflected to incoming solar radiations to the measurement uncertainty better than ± 0.28 %, at around the L1 halo orbit. We present the optical performance evaluation of a new CPC designed to satisfy required optical efficiency and spectral flatness over 0.2 to 4.0 ?m in shortwave (SW) radiation wavelength range. The CPC was manufactured with electroless nickel plating aluminum. It has 23° in acceptance angle, 4.45 mm in focal length of parabola, 26.83 ± 0.05 mm in overall length, 8.19 ± 0.01 mm and 3.20 ± 0.01 mm in radii of entrance and exit apertures, respectively. Its parabolic surface was finished to the surface roughness of less than 3 nm Ra and coated with protected aluminum for average reflectance over 80 % in the wavelength range. The test setup was constructed as distant small source (DSS) configuration using quartz tungsten halogen (QTH) lamps, infrared emitters, collimators, filters and the NIST traceable calibrated sensors. Within the CPC acceptance angle and wavelength range, the CPC optical efficiency and spectral flatness were measured. It implies that the measurement uncertainty corresponds to less than ± 0.28 %. The study proves that the new CPC can be used in measurement of ratio of reflected to incoming solar radiations around the L1 halo orbit.

9607-51, Session 11

Development of low optical cross talk filters for VIIRS for JPSS

Vijay Murgai, Derek Hendry, Raytheon Space and Airborne Systems (United States); Kevin R. Downing, Dave Carbone, Materion Barr Precision Optics & Thin Film Coatings (United States)

The Visible/Infrared Imaging Radiometer Suite (VIIRS) is a key sensor on Suomi National Polar-orbiting Partnership (NPP) satellite launched on October 28, 2011 into a polar orbit of 824 km nominal altitude and the JPSS sensors currently being built. VIIRS collects radiometric and imagery data of the Earth's atmosphere, oceans, and land surfaces in 22 spectral bands spanning the visible and infrared spectrum from 0.4 to 12.5 ?m. Interference filters assembled in 'butcher-block' arrays are used close to focal plane arrays for spectral definition. Out-of-band signal and out-of-band optical cross-talk was observed for bands in the 0.4 to 1 ?m range in testing of VIIRS for NPP. Optical cross-talk is in-band or out-of-band light incident on an adjacent filter or adjacent region of the same filter reaching the detector. Out-of-band optical cross-talk results in spectral and spatial 'impurities' in the signal and consequent errors in the calculated environmental parameters such as ocean color that rely on calculations based on combinations of signals from more than one band.

This paper presents results of characterization, specification, and coating process improvements that enabled production of filters with significantly reduced out of band light for JPSS J1 and subsequent sensors. Total transmission and scatter measurements at a wavelength within the pass band can successfully characterize filter performance prior to cutting and assembling into the butcher block assemblies. Coating and process development demonstrated performance on test samples followed by production of filters for J1 and J2. Results for J1 and J2 filters will be presented.

9607-52, Session 11

An update on EUMETSAT programmes and plans

K. Dieter Klaes, Kenneth Holmlund, EUMETSAT (Germany)

EUMETSAT as an inter governmental organisation representing 30 European Member States and one cooperating state is contributing space based observations for operational meteorology and climate monitoring. These observations are collected from the geostationary and sun-synchronous polar orbits though satellites systems developed and operated in the frame of mandatory programmes. In the frame of optional programmes further observations for altimetry and oceanography are provided. Through third party programmes, EUMETSAT provides data from other agencies' satellites to the user community. In summer 2015 EUMETSAT plans to launch MSG-4, which will complement the current operational fleet of operational geostationary spacecraft, namely the Meteosat-7, which is the last satellite of the first generation and the three satellites of the Second Generation of Meteosat (Meteosat Second Generation (MSG-1, MSG-2 and MSG-3)), Meteosat-8, Meteorsat-9 and Meteosat-10. MSG-4 will be stored in orbit after successful commissioning. The MSG Programme has been developed in co-operation between EUMETSAT and ESA. Two satellites of the EUMETSAT Polar System (EPS) are currently in orbit. Metop-B, the second of a series of three satellites, was launched in September 2012 and is the prime operational satellite. Metop-A, the first of the series is in orbit since October 2006. The satellites provide operational services in parallel operations from the mid-morning polar orbit. They belong to the Initial Joint Polar System (IJPS) with the US. The EUMETSAT Advanced Retransmission Service (EARS) provides observations from partner HRPT (High Resolution Picture Transmission) stations. EUMETSAT's first optional programme exploits the data from the Jason-2 satellite. Operational Ocean Surface Topography information services are provided since summer 2008. Jason-2 is a joint programme with CNES, NOAA and NASA. In a follow on Jason-3 optional programme the Jason-3 satellite is prepared for a lunch in summer 2015. To assure continuity development of Meteosat Third Generation (MTG) and the preparations for EPS-SG (EPS Second Generation) are ongoing. The MTG programme is now in Phase C and the development is proceeding. EPS-SG is currently in phase B under a preparatory programme and the full programme approval is expected in 2015. In the frame of the Copernicus Programme (formerly GMES (Global Monitoring for Environment and Security)) EUMETSAT will operate the marine part of the Sentinel-3 satellites.

9607-53, Session 11

The convergence of earth science and applications from space: it's not your grandparents' R2O

Philip E. Ardanuy, Raytheon Intelligence & Information Systems (United States); Molly K. Macauley, Resources for the Future (United States); William B. Gail, Global Weather Corp. (United States); William H. Hooke, American Meteorological Society (United States)

Fifty-five years after the first weather satellite was launched into orbit, constellations and trains of meteorological and environmental satellites are now enabling routine Earth System Science from space. In addition to the tremendous advances in core science obtained from NASA, NOAA, USGS, and international-partner Earth observations, the Earth System Science community has had extraordinary success in building applications of significant societal value that leverage these data. Indeed, the applications science community has achieved a critically important milestone. It has successfully completed its incubation phase, characterized by efforts to educate mission planners and end-users about the benefits of applications along with the skills and tools required to obtain those benefits. Compelling evidence shows the community has transitioned to the demand phase, in which its investment has begun to succeed, its value is becoming well recognized, and its services are increasingly demanded. Demand for societal use of Earth information is growing rapidly, in some cases perhaps faster than the funding of basic Earth System Science itself. This transition requires fundamental changes in how the pure science research and applied research/scientific applications organizations operate virtually as a single enterprise in order to properly serve the rapidly growing need for their services. We are entering an era where research, operations, and applications are becoming an integrated system rather than distinct disciplines. This implies a need for profoundly improved interfaces between these three areas of our enterprise.

9607-54, Session 11

Collaboration tools for optimizing 'operational' climate monitoring from space

Douglas B. Helmuth, Lockheed Martin Corp. (United States)

Consistently collecting the earth's critical climate signatures (atmosphere, oceans, and terrestrial) remains a priority for world governments and international scientific organizations. Architecting optimized earth observing constellation solution(s) requires transforming today's scientific missions into an optimized robust 'operational' constellation that addresses the needs of decision makers, scientific investigators and global users for trusted data.

The application of new tools offers paths forward for global architecture collaboration of Remote Sensing Platforms in Constellation. This year rule-based expert system (RBES) modeling runs have been made optimized the intended but maligned NPOESS architecture, and become a surrogate for a global operational climate monitoring architecture(s). This rule-based systems tool delivers valuable insights for Global climate architectures, through the valuations of alternatives considered and the exhaustive range of trade space explored. Results from a more complex constellation optimization for monitoring/collecting Global Essential Climate Variables (ECV's) are discussed in detail with explanations and thoughts on

appropriate rule-based valuations. This specific modeling case is a global capabilities based example of an 'operational' climate-centric case study. This science traceability optimizing tool can be used to compare the relative value for hundreds of thousands of different possible architectures.

The paper & presentation includes graphic representation(s) of the architecture trade space(s) considered and the sensor/platform combinations that suggest and support collaborative paths forward. The material is intended for audience interaction and responses from climate scientists & national/regional decision makers.

9607-55, Session 12

S-NPP VIIRS instrument telemetry and calibration data trend study

ZiPing Sun, Frank J. De Luccia, Jason C. Cardema, Gabriel Moy, The Aerospace Corp. (United States)

The Suomi National Polar Orbiting Partnership (S-NPP) VIIRS (Visible Infrared Imaging Radiometer Suite) employs a large number of temperature and voltage sensors (telemetry points) to monitor instrument health and performance. We have collected data and built tools to study telemetry and calibration parameters trends. The telemetry points are organized into groups based on locations and functionalities. Examples of the groups are: telescope motor, focal plane array (FPA), scan cavity bulkhead, radiators, solar diffuser and solar diffuser stability monitor. We have performed daily monitoring and long-term trending studies. Daily monitoring processes are automated with alarms built into the software to indicate if pre-defined limits are exceeded. Long-term trending studies focus on instrument performance and sensitivities of Sensor Data Record (SDR) products and calibration look-up tables (LUTs) to instrument temperature and voltage variations.

VIIRS uses a DC Restore (DCR) process to periodically correct the analog offsets of each detector channel of each spectral band to ensure that the FPA output signals are always within dynamic range of the Analog to Digital Converters (ADCs). The offset values are updated based on observations of the On-Board Calibrator Blackbody (OBC BB) source. We have performed long-term trend study of DCR offsets and calibration parameters to explore connections of the DCR offsets with calibration parameters. The study also shows how the instrument and calibration parameters respond to the VIIRS Petulant Mode, spacecraft (SC) anomalies and flight software updates. These studies may help to improve calibration LUTs and SDR Quality Flags.

9607-56, Session 12

Trending of SNPP ephemeris and its implications on VIIRS geometric performance

Guoqing Lin, Science Systems and Applications, Inc. (United States); Robert E. Wolfe, NASA Goddard Space Flight Ctr. (United States); Masahiro Nishihama, Science Systems and Applications, Inc. (United States)

This paper describes the trending results of the ephemeris data in the three and half years of operations of the Suomi National Polar?orbiting Partnership (SNPP) spacecraft since its launch in October 2011. The ephemeris data includes time stamped positions and velocities, which are used to derive altitudes and speeds. The orbital mean altitude has been maintained at 838.8 km through drag make-up maneuvers for. The mean speed is 7524 m/s with orbital period of 101.5 minutes. The altitude above the Equator is 829.8 km to within +/- 1 km peak-to-valley. Within an orbit, the altitude varies from 828 km to 856 km and the speed varies from 7503 m/s to 7537 m/s. The local time of ascending node drifted slowly from 13:25:24 GMT at launch to 13:23:02 in November 2012, then back to 13:33:40 as of 16 October 2014. With four inclination adjustments, the inclination angle started drifting down, probably back to and maintained around 13:25:00.

The Visible Infrared Imaging Radiometer Suite (VIIRS) instrument onboard the SNPP satellite has a swath width of 3055 km over the Equator, making observations once a day over the Equator both in the day side and night side without under-lap from one scan to the next or from one orbit to the next. For latitude above 55 (TBR) degrees in the northern hemisphere or below -55 (TBR) degrees in the southern hemisphere, VIIRS makes daily observations two or more times, up to 14 times over the poles.

9607-57, Session 12

Mission history of reflective solar band calibration performance of VIIRS

Gabriel Moy, Kameron Rausch, Evan Haas, Timothy S. Wilkinson, Jason C. Cardema, Frank J. De Luccia, The Aerospace Corp. (United States)

The VIIRS sensor onboard Suomi-NPP has 22 bands spanning the visible and infrared wavelengths from 0.4 to 12.5 um. The 14 reflective solar bands (RSB) are calibrated using solar radiance reflected from a Solar Diffuser (SD) and a dark reference from a Space View (SV). A Solar Diffuser Stability Monitor (SDSM) tracks the degradation of SD reflectance, measured by a derived parameter known as the "H factor". The ratio between calculated SD radiance, which includes the H factor, and the VIIRS measured SD radiance is known as the "F factor". Ground processing uses the F factor and the pre-launch measured instrument characteristics on which it depends to generate calibrated radiances and reflectances contained in the Sensor Data Record (SDR).

In this paper we discuss improvements to data product quality over the mission history through Look-Up Table (LUT) and algorithmic code changes, such as automated RSB calibration (RSBAutocal). The current operational calibration uses manually derived, weekly updates of predicted F LUTs that go into operation a week after delivery. As a result, calibration data are applied one to two weeks after their collection, resulting in significant predict-ahead errors. Another consequence of the weekly LUT update process is that anomalous trend changes in F factors may not be recognized and compensated for many weeks. Once RSBAutocal is operational, calibration will occur every orbit, eliminating both predict-ahead and trend change errors and thereby improving data product quality.

9607-58, Session 12

VIIRS reflective solar bands calibration improvements with hybrid approach

Junqiang Sun, National Oceanic and Atmospheric Administration (United States) and Global Science & Technology, Inc. (United States); Menghua Wang, NOAA National Environmental Satellite, Data, and Information Service (United States)

The on-orbit calibration of the reflective solar bands (RSBs) of the Visible Infrared Imaging Radiometer Suite (VIIRS) and the result from the analysis of the up-to-date 4 years of mission data are presented. The VIIRS solar diffuser (SD) and lunar calibration methodology are discussed, and the calibration coefficients, called F-factors, for the RSBs are given for the latest reincarnation. The coefficients derived from the two calibrations are compared and the uncertainties of the calibrations are discussed. Each calibration has advantages and disadvantages. Lunar calibration can provide long-term stable calibration coefficients, while SD/SDSM calibration is feasible every orbit. By combining the calibration coefficients of SD and lunar calibration, we produce a set of lookup tables (LUTs) that is the optimal result up to date and its accuracy level is estimated at ~0.2%. This hybrid approach highlights an important progress in calibration and it is made possible by the design change in VIIRS instrument layout allowing both the SD and the Moon to be viewed by RSB to be at the same angle of incidence (AOI). We assess the improvement to the ocean color products by comparing the official output to the new result and show the significant improvement.

9607-59, Session 13

Progress in the on-orbit calibration of SNPP VIIRS for ocean data applications

Robert E. Eplee Jr., Kevin R. Turpie, Gerhard Meister, Frederick S. Patt, Bryan A. Franz, NASA Goddard Space Flight Ctr. (United States)

The NASA Ocean Biology Processing Group has continued monitoring the SNPP VIIRS on-orbit calibration since the derivation of the calibration for Reprocssing 2014.0 of the VIIRS ocean color data set, which was based on solar and lunar observations through July of 2014. The VIIRS instrument calibration model developed for Reprocessing 2014.0 continues to hold true for data obtained through July of 2015. The optimum normaliztion for the SDSM-derived H-factors used in correcting the solar diffuser BRDF degradation is the detrended SDSM channel 8 time series. The optimum fits for the solar observations are exponential plus linear function of time for bands M1-M4 and simultaneous exonential functions of time for bands M5-M7. The optimum fits for the lunar observations are simultaneous exponentials of time plus linear functions of the sub-spacecraft point libration angles. Comparison of the solar and lunar time series show that lunar-derived adjustments of the solar time series are significant for bands M1, M3, and M4. The solar calibration time series shows an RMS error per band of 0.068-0.16%. The lunar calibration time series shows an RMS error per band of 0.070-0.24%. Due to the on-orbit aggregation of the band M6 lunar data, the scatter in the lunar time series is higher for this band than for the dual gain bands. Discounting the M6 lunar calibrations, the RMS errors for the lunar data are 0.070-0.17%, which are comparable to the solar residuals. The relative differences in the two trends are 0.10-0.24%, or 0.10-0.14% discounting the band M6 observations.

9607-60, Session 13

Propagation of visible infrared imaging radiometer suite (VIIRS) calibration uncertainty trends to ocean color data

Kevin R. Turpie, Univ. of Maryland, Baltimore County (United States); Robert E. Eplee Jr., SAIC (United States); Gerhard Meister, NASA Goddard Space Flight Ctr. (United States)

During the first few years of the Suomi National Polar-orbiting Partnership (NPP) mission, the NASA Ocean Color calibration team continued to improve on their approach to the on-orbit calibration of the Visible Infrared Imaging Radiometer Suite (VIIRS). As the calibration was adjusted for changes in ocean band responsitivity, the team also estimated a theoretic residual error in the calibration trends well within a few tenths of a percent, which could be translated in to trend uncertainties in regional time series of surface reflectance and derived products, where biases as low as a few tenths of a percent in certain bands can lead to significant effects. This study looks at effects from spurious trends inherent to the calibration and biases that arise between reprocessing efforts because of extrapolation of the time-dependent calibration table. With the addition of new models for instrument and calibration system trend artifacts, new calibration trends led to improved estimates of ocean time series uncertainty. Table extrapolation biases are presented for the first time. The results further the understanding of uncertainty in measuring regional and global biospheric trends in the ocean using VIIRS, which better define the roles of such records in climate research.

9607-61, Session 13

JPSS-1 VIIRS Prelaunch RSB RVS characterization and water vapor correction

ShihYan Lee, ERT, Inc. (United States); Changyong Cao, NOAA National Environmental Satellite, Data, and Information Service (United States)

The accuracy of pre-launch VIIRS response versus scan angle (RVS) characterization is vitally important to the quality of calibrated radiance products. The RVS correct the optical system's scan angle dependency with respect to the calibrator scan angle. In this document, we describe the methodology used in JPSS-1 RSB RVS characterization and the efficacy of MODTRAN5 in water vapor correction. The RVS is characterized using a 2nd order polynomial fit over the measured scan angles. The results show high fitting accuracy with uncertainty of 0.05% of less for all bands except for M9 due to water vapor absorption. To improve M9 RVS, MODTRAN5 is used to correction water vapor absorption variation during the RVS measurements. This correction reduced M9 RVS uncertainty from ~0.2% to ~0.07% with a RVS that is up to 0.4% difference compared with RVS prior to correction.

9607-62, Session 13

Stellar calibration of the Suomi-NPP VIIRS day-night band high gain

Jon P. Fulbright, Science Systems and Applications, Inc. (United States); Xiaoxiong Xiong, NASA Goddard Space Flight Ctr. (United States)

The Day-Night Band (DNB) of the VIIRS instrument on Suomi-NPP has a remarkable dynamic range, and its high gain stage has extreme low-light sensitivity. The specification for the low radiance limit of the high gain state of the DNB is 3x10-9 W cm-2 sr-1, which means bright stars and planets are readily detectible when the DNB is viewing deep space. In this paper we describe how these stellar measurements can be used to calibrate the high-gain stage of the DNB. The process includes determining which stars are crossing the SV field-of-view at a given time, computing the stellar radiance, and the computation of the gain trending. We also describe some of the complications and limits to this method, including undersampling of the stellar image, saturation, and crowding. Most stars have minimal variability, and the stars detectible by the DNB are mostly well-studied and any known variable stars can be discarded as calibration sources. We present the relative gain trending for the duration of the mission, which includes over 4500,000 measurements of over 3500 bright stars in the first three years on-orbit. We also show how spectrophotometric flux standard stars can be used to set an absolute radiance scale for the high-gain stage. Finally, we present results from our analysis of the S-NPP VIIRS Deep Space maneuver, which includes measurements of the DNB gain linearity and gain switching point.

9607-63, Session 14

Assessment of MODIS and VIIRS solar diffuser on-orbit degradation

Xiaoxiong J. Xiong, Jim Butler, NASA Goddard Space Flight Ctr. (United States); Amit Angal, Zhipeng Wang, Science Systems and Applications, Inc. (United States)

Both MODIS and VIIRS instruments use a solar diffuser (SD) system for their reflective solar bands on-orbit calibration. On-orbit changes in its bi-directional reflectance factor is tracked by a solar diffuser stability monitor (SDSM) using its alternate measurements of direct sunlight through an attenuation screen and the sunlight diffusely reflected off the SD. The SDSM calibration data are collected by a number of filtered detectors, covering wavelengths from 0.41 to 0.94 microns. This paper provides an in-depth assessment of both Terra and Aqua MODIS and S-NPP VIIRS SD on-orbit degradation. It examines the dependency of SD on-orbit degradation on spectral wavelength as well as solar exposure time. Due to different launch dates, operation configurations, and calibration frequencies, the Terra and Aqua MODIS and S-NPP VIIRS SD have experienced quite different amount of SD degradation. In general, however, the shorter the wavelength, the larger is the SD on-orbit degradation. Also illustrated in paper is roughly the same rate of SD on-orbit degradation over solar exposure time for all three

instruments. Lessons learned from this assessment will help future earth observing sensors for their SD calibration system design, on-orbit operation, and calibration.

9607-64, Session 14

Out-of-band response and the Suomi-NPP solar diffuser stability monitor

Jon P. Fulbright, Ning Lei, Zhipeng Wang, Science Systems and Applications, Inc. (United States); Xiaoxiong Xiong, NASA Goddard Space Flight Ctr. (United States)

The Suomi-NPP VIIRS Solar Diffuser Stability Monitor (SDSM) is a crucial component of the calibration of the Reflected Solar Bands (RSB). The SDSM observes the Solar Diffuser (SD) to determine the amount of degradation affecting the Bidirectional Reflectance Distribution Function (BRDF) due to on-orbit exposure to UV light. The SDSM performs measurements in eight filtered bands covering the 410 to 926 nm wavelength range. The degradation of the SD in these eight bands is quantified by the H-factor. The SDSM has performed very well over the course of the SNPP mission, but concerns have been raised about whether the filters used in the SDSM have significant out-of-band (OOB) transmission. Possible OOB effects were not fully characterized pre-launch for the VIIRS SDSM, and therefore the potential influence on the on-orbit calibration has not been included into the H-factor measurements. We present the results of our efforts to: 1) quantify the magnitude of the possible OOB effect on the H -factors, and 2) use additional VIIRS observations, such as lunar and Earth-view data, to learn more about the existence of any OOB effect.

9607-65, Session 14

Estimation of the accuracy of the SNPP VIIRS solar diffuser BRDF degradation factor determined by the on-board solar diffuser stability monitor

Ning Lei, Science Systems and Applications, Inc. (United States); Xiaoxiong Xiong, NASA Goddard Space Flight Ctr. (United States)

The radiometric calibration of the reflective solar bands of the Visible Infrared Imaging Radiometer Suite (VIIRS) aboard the Suomi National Polar-orbiting Partnership (SNPP) satellite relies on observing an onboard solar diffuser (SD). Once on orbit, the SD bidirectional reflectance distribution function (BRDF) degrades over time. An onboard solar diffuser stability monitor (SDSM) is used to determine the degradation. The degradation factor is derived from the response ratio when the SDSM detectors observe the Sun through a pinhole screen and the fully solar radiation illuminated SD through another pinhole screen at almost the same time. Consequently, it is crucial to determining accurately the ratio of the SDSM screen transmittance and the product of the SD screen transmittance and the SD BRDF at the initial time when the BRDF just starts to degrade. In order to accurately determine the screen transmittances, once on orbit, satellite yaw maneuvers were performed. Previously, we determined the SDSM screen transmittance with both yaw maneuver and a small portion of regular on-orbit data. Similarly, here we use both yaw maneuver and a small portion of regular on-orbit data to determine the product of the SD screen transmittance and the SD BRDF at the initial time. Importantly, we consider the impact of the angular dependence of the BRDF degradation factor. We fit a semi-physical model to the measured degradation factor to determine the measurement accuracy.

9607-66, Session 14

Determination of the SNPP VIIRS solar diffuser BRDF degradation factor over wavelengths not covered by the SDSM detectors

Ning Lei, Science Systems and Applications, Inc. (United States); Xiaoxiong Xiong, NASA Goddard Space Flight Ctr. (United States)

Once on orbit, the bidirectional reflectance distribution function (BRDF) of the solar diffuser (SD) of the Visible Infrared Imaging Radiometer Suite (VIIRS) aboard the Suomi National Polar-orbiting Partnership (SNPP) satellite degrades over time. The degradation factor is determined by an onboard solar diffuser stability monitor (SDSM). However, the central wavelengths (412 to 926 nm) of the SDSM detectors do not cover the VIIRS short wave infrared (SWIR) bands which have central wavelengths from 1238 to 2257 nm. Although it is known that the SD BRDF degrades at a much smaller rate over longer wavelengths, the degradation over some of the SWIR bands' central wavelengths may still be large enough to be ignored since Ocean Color products often require a radiometric calibration accuracy of at least 0.1%. To address the SD BRDF degradation factor over the SWIR bands wavelength region, we investigate a phenomenological theory and apply the theory to determine the SD BRDF degradation factor over the SWIR bands wavelength region.

9607-67, Session 14

Investigation of the solar diffuser degradation non-uniformity

Junqiang Sun, National Oceanic and Atmospheric Administration (United States) and Global Science & Technology, Inc. (United States); Mike Chu, National Oceanic and Atmospheric Administration (United States) and ERT, Inc. (United States); Menghua Wang, NOAA National Environmental Satellite, Data, and Information Service (United States)

The solar diffuser (SD) is the key component of the onboard calibration of the solar reflective bands (RSB) for many global monitoring instruments. Crucial in the use of the SD in the calibration of the RSB is a working assumption that the reflectance property of the SD remains the same functional form throughout degradation apart from an overall factor. In this work, we examine the angle dependence of SD degradation in the Visible Infrared Imaging Radiometer Suite (VIIRS) onboard Suomi National Polar orbiting Partnership (SNPP) satellite as well as other satellite sensors. An important and common step in the standard radiometric calibration methodology of the RSB is the input of the SD degradation result measured by the solar diffuser stability monitor (SDSM). It has been implicitly assumed that the SD degradation measured at the angle toward the SDSM is the same as the SD degradation toward the direction of the RSB location, but non-uniform degradation can invalidate this condition given that the SDSM and the RSB are at different outgoing angles with respect to the RSB. The evidence revealed by our analysis shows a clear evolving dependency, in particular, for short-wavelength bands for all sensors examined, on the solar declination angle over time that invalidates the current practice. We present the analysis, the result and a discussion on the implication for on-orbit calibration using SD going forward.

9607-68, Session 14

Impact of the angular dependence of the SNPP VIIRS solar diffuser BRDF degradation factor on the radiometric calibration of the reflective solar bands

Ning Lei, Science Systems and Applications, Inc. (United States); Xiaoxiong Xiong, NASA Goddard Space Flight Ctr. (United States)

The Visible Infrared Imaging Radiometer Suite (VIIRS) aboard the Suomi National Polar-orbiting Partnership (SNPP) satellite carries out radiometric calibration of its reflective solar bands (RSBs) primarily through observing an onboard solar diffuser (SD). The SD optical scattering property is measured by a bidirectional reflectance distribution function (BRDF). Once on orbit, the BRDF degrades over time and the degradation factor is determined by an onboard solar diffuser stability monitor (SDSM) which observes the Sun (through a pinhole screen) and the SD (through another screen with holes) at almost the same time. We showed in a previously SPIE proceeding that the BRDF degradation factor is angle dependent. Consequently, due to that the SDSM and the VIIRS telescope SD views have different angles, applying the BRDF degradation factor determined from the SDSM without any adjustments to the VIIRS RSB calibration can result in large systematic errors. In addition, the BRDF angular dependence has impacts on the determinations of the SD attenuation screen transmittances viewed by both the SDSM detectors and the VIIRS telescope. In this proceeding, we first determine the SD attenuation screen viewed by the VIIRS telescope with the impact of the SD BRDF angular dependence, using both yaw maneuver and regular on-orbit data (we show the determination of the SD attenuation screen transmittance viewed by the SDSM elsewhere). Then we explore how we can apply the degradation factor obtained from SDSM SD observations to the VIIRS RSB radiometric calibration.

9607-69, Session 15

Calibration improvements for MODIS and VIIRS SWIR spectral bands

Xiaoxiong J. Xiong, NASA Goddard Space Flight Ctr. (United States); Amit Angal, Jon P. Fulbright, Ning Lei, Zhipeng Wang, Aisheng Wu, Science Systems and Applications, Inc. (United States)

Both MODIS and VIIRS use a solar diffuser (SD) to calibrate their reflective solar bands (RSB), covering wavelengths from 0.41 to 2.3 microns. On-orbit change of the SD bi-directional reflectance factor (BRF) is tracked by an on-board solar diffuser stability monitor (SDSM). The current SDSM design, however, only covers the spectral range from 0.41 to 0.93 microns. In general, the SD degradation is strongly wavelength dependent with larger degradation occurring at shorter wavelengths, and the degradation in the SWIR region is expected to be extremely small. As each mission continues, however, the impact due to SD degradation at SWIR needs to be carefully examined and the correction if necessary should be applied in order to maintain the calibration quality. For Terra MODIS, alternative approaches have been developed and used to estimate the SD degradation for its band 5 (1.24 microns) and a time-dependent correction has already been applied to the current level 1B (L1B) collection 6 (C6). In this paper, we will describe different methodologies that can be used to examine the SD degradation and their applications for both Terra and Aqua MODIS and S-NPP VIIRS SWIR calibration. These methodologies include but not limited to the use of lunar observations, Pseudo Invariant Calibration Sites (PICS), band-to-band relative calibration, and a differential approach.

9607-70, Session 15

Update on the performance of Suomi-NPP VIIRS lunar calibration

Zhipeng Wang, Jon Fulbright, Science Systems and Applications, Inc. (United States); Xiaoxiong Xiong, NASA Goddard Space Flight Ctr. (United States)

Lunar observations have been regularly scheduled for the Visible Infrared Imaging Radiometer Suite (VIIRS) instrument aboard the Suomi National Polar-orbiting Partnership (S-NPP) satellite since its launch on October 28th, 2011. In reference to the ROLO irradiance model, the detector gain coefficient or F-factor can be derived from these lunar observations for the reflective solar bands (RSB). Unlike its predecessor Moderate Resolution Imaging Spectro-radiometer (MODIS), the Moon and the on-board solar diffuser (SD) are viewed by VIIRS detectors at the same angle of incidence (AOI) to the half angle mirror (HAM). Eliminating the impact from the variation in the instrument response to the HAM AOI, this design allows the detector gain changes tracked by the Moon and the SD to be directly compared. In this paper, we update the lunar F-factors from the scheduled lunar calibration. The long-term trends of the lunar F-factor trending and the SD F-factor trending still agree in general for all RSBs. We also calculate the lunar F-factor at detector level and compare the detector dependency of the lunar F-factor and the SD F-factor. For a few RSBs at shorter wavelengths, a bias of up to 1% between the two has been identified. Using the detector-dependent lunar F-factors will decrease the retrieved Earth view radiance of lower-number detectors in relative to higher-number detectors than the SD F-factors. The inconsistency indicates systematic bias between the lunar and SD calibration approaches.

9607-71, Session 15

Improved VIIRS offset correction during lunar intrusion into space view

Peter J. Isaacson, Frank J. De Luccia, Gabriel Moy, Nicholas R. Vandermierden, The Aerospace Corp. (United States)

The Suomi NPP VIIRS is a scanning radiometer designed to collect measurements that support a diverse range of operational and science applications. VIIRS radiometric calibration requires a zero radiance source to determine the background level. This background level, due to both dark current and electronic offsets, must be removed from the instrument digital output to determine the contribution from the earth scene radiance of interest.

The VIIRS space view (SV) is employed to determine the background level. The space view digital output is applied as an additive (offset) term in the VIIRS radiometric calibration. However, the SV is occasionally “contaminated” by viewing the Moon, which leads to substantially higher SV counts than would be expected for cold space. The VIIRS calibration algorithms have a catch for this situation, but it is conservative, leading to “false positives” in which scans are flagged as contaminated when they actually view cold space. Furthermore, when scans are flagged as lunar contaminated, the VIIRS calibration algorithms use alternate data sources as substitute SV observations, and the data are flagged as poor quality.

In this work, we present a new technique for evaluating the lunar contamination of VIIRS scans. For scans that are only partially contaminated (that “see” both lunar contamination and cold space), this technique enables calculation of the zero radiance offset from the same scan, rather than relying on alternate sources. This approach could potentially reduce the need to flag scans for which the Moon contaminates the SV as lower quality.

9607-72, Session 15

An improved algorithm for VIIRS band-to-band registration characterization with lunar observation

Zhipeng Wang, Science Systems and Applications, Inc. (United States); Xiaoxiong J. Xiong, NASA Goddard Space Flight Ctr. (United States); Yonghong Li, Science Systems and Applications, Inc. (United States)

Since launch, lunar observations have been performed on a regular basis for the Visible Infrared Imaging Radiometer Suite (VIIRS) instrument aboard the Suomi National Polar-orbiting Partnership (S-NPP) satellite. Unlike its predecessor Moderate Resolution Imaging Spectro-radiometer (MODIS), VIIRS has no on-board calibrator to perform the on-orbit spatial characterization. Therefore, the methodologies for spatial characterization using the Moon that have been developed for MODIS are extended for VIIRS. One of the key spatial parameters is the band-to-band registration (BBR) in both along-scan and along-track directions. While the lunar BBR results can satisfactorily show that the long-term stability of VIIRS BBR meets the design requirement specification of ±0.1 M-band pixels, seasonal oscillations have been observed in the BBR results, mostly noticeable between the visible/near infrared bands and short/middle wave infrared bands. This paper investigates the cause of this oscillation. It is found that the oscillation is correlated with the orientations of the lunar images that rotate from event to event. After figuring out an approach to quantify the rotation and compensate its impact, current BBR algorithm is improved and the seasonal oscillation in the BBR results is significantly reduced from up to ±0.05 M-band pixels to less than ±0.01 M-band pixels. With suppressed seasonal oscillation, the actual BBR can be derived and its long-term drift is easier to be identified.

9607-73, Session 15

S-NPP VIIRS TEB detector noise analysis using ICVS linear gain

Taeyoung J. Choi, NOAA National Environmental Satellite, Data, and Information Service (United States) and ERT, Inc. (United States); Changyong Cao, Fuzhong Weng, NOAA National Environmental Satellite, Data, and Information Service (United States)

The Soumi-NPP Visible Infrared Imaging Radiometer Suite (VIIRS) was launched on October 28th, 2011 and its Sensor Data Record (SDR) product was reached maturity status in March of 2014. Although the VIIRS SDR products gained the ‘validated maturity’ state, there were remaining issues such as residual stripings in the scan direction in some thermal bands. These horizontal striping issues in the Thermal Emissive Bands (TEBs) were reported by Sea Surface Temperature (SST) Environmental Data Record (EDR) group. The observed noise patterns had up to ±0.2 K level especially in the band M14 and M15.

As an independent source of calibration, the Solar Diffuser (SD) is utilized in this study. The SD is originally designed for the Reflective Solar Band (RSB), however, it is assumed to be thermally stable at the time of SD observation. Residual thermal transitions are removed by applying a simple differentiation filtering. For each detector, a linear gain developed by Integrated Calibration and Validation System (ICVS) is applied to convert digital number (DN) to radiance unit. After the conversion, noise analyses are performed within the SD scan and among the scan-averaged responses.

Conference 9608: Infrared Remote Sensing and Instrumentation XXIII

Monday - Wednesday 10–12 August 2015

Part of Proceedings of SPIE Vol. 9608 Infrared Remote Sensing and Instrumentation XXIII

9608-1, Session 1

Rosetta and 67p/ Churyumov - Gerasimenko: a comet under observation *(Invited Paper)*

Gabriele E. Arnold, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany)

After a ten year's expedition through the Solar system Europe's comet chaser Rosetta arrived at comet 67 P/ Churyumov-Gerasimenko in August 2014. Less than 100 kilometers from the nucleus the eleven orbiter payload instruments started to map and characterize the comet in great detail. In November 2014 Philae was the first robotic subsystem ever that landed on a cometary surface performing in situ measurements with ten instruments. The mission's scientific program following the deployment of Philae is determined by the activity of the comet, which will increase as 67P approaches perihelion in August 2015.

This paper introduces the mission goals and profile. It gives an overview of some of the preliminary results of the mission. Selected results gained during the pre-landing phase of the subsystem Philae's subsystem and the comet's escort phases are discussed.

9608-2, Session 1

VIRTIS on Rosetta: a unique technique to observe comet 67p/Churyumov - Gerasimenko: first results and prospects

Gabriele E. Arnold, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany); Fabrizio Capaccioni, INAF - IASF Roma (Italy); Gianrico Filacchione, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Stéphane Erard, Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Dominique Bockelee-Morvan, Antonella Barucci, Observatoire de Paris à Meudon (France); Maria Cristina De Sanctis, Ernesto Palomba, Maria Teresa Capria, Priscilla Cerroni, INAF - IASF Roma (Italy); Pierre Drossart, Florence Henry, Cedric Leyrat, Observatoire de Paris à Meudon (France); Giuseppe Piccioni, INAF - IASF Roma (Italy); Bernard Schmitt, Lab. d'Astrophysique de l'Observatoire de Grenoble (France); Frederico Tosi, INAF - IASF Roma (Italy); Gian Paolo Tozzi, INAF - Osservatorio Astrofisico di Arcetri (Italy)

VIRTIS aboard ESA's Rosetta mission is a complex imaging spectrometer that combines three unique data channels in one compact instrument to study nucleus and coma of comet 67P/Churyumov-Gerasimenko. Two of the spectral channels are dedicated to spectral mapping (-M) at moderate spectral resolution in the range from 0.25 to 5.1 ?m. The third channel is devoted to high resolution spectroscopy (-H) between 2 and 5 ?m. The VIRTIS-H field of view is approximately centered in the middle of the -M image. The spectral sampling of VIRTIS-M is 1.8 nm/band below 1 μm and 9.7 nm/band between 1-5 μm, while for VIRTIS-H ?/??= 1300-3000 in the 2-5 μm range.

This paper describes selected findings during the pre-landing phase of Philae's robotic subsystem and the comet's escort phase as well as prospects of further observations. The preliminary results include studies of surface composition, coma analyses and temperature retrieval for the nucleus surface-coma system demonstrating the capability of the instrument.

VIRTIS was developed by a consortium under the scientific direction of the Institute for Space Astrophysics and Planetology (IAPS, INAF), in Rome (I). The consortium includes the Laboratory for Space Studies and Astrophysics Instrumentation (LESIA) of the Observatoire de Paris (F) and the DLR Institute of Planetary Research in Berlin (G). The development of the instrument was funded by the national space agencies ASI, CNES, and DLR. The authors gratefully acknowledge the support from the Rosetta and VIRTIS science, instrument, and operation teams.

9608-3, Session 1

MERTIS: geometrical calibration of thermal infrared optical system by applying diffractive optical elements

Martin Bauer, Technische Univ. Berlin (Germany) and Technische Fachhochschule Wildau (Germany)

Geometrical sensor calibration is essential for space applications based on high accuracy optical measurements, in this case for the thermal infrared push-broom imaging spectrometer MERTIS. The goal is the determination of the interior sensor orientation. A conventional method is to measure the line of sight for a subset of pixels by single pixel illumination with collimated light. To adjust angles which define the line of sight of a pixel a manipulator construction is used.

A new method for geometrical sensor calibration is using Diffractive Optical Elements (DOE) in connection with laser beam equipment. Diffractive optical elements (DOE) are optical microstructures which are used to split an incoming laser beam with a dedicated wavelength into a number of beams with well-known propagation directions. As the virtual sources of the diffracted beams are points at infinity which gives an image invariant against translation. This particular feature allows a complete geometrical sensor calibration with one image avoiding complex adjustment procedures which means a significant reduction of calibration effort.

We present a method for geometrical calibration of thermal infrared optical system. The fundamentals of this approach of infrared optical system calibration by applying diffractive optical elements are discussed. The demonstrated results underpin the consistency between simulation and real data.

9608-4, Session 1

MERTIS FM: optical performance of the thermal infrared push-broom imaging spectrometer

Martin Bauer, Technische Univ. Berlin (Germany)

The Mercury Radiometer and Thermal Infrared Spectrometer (MERTIS) onboard the BepiColombo Mercury Planetary Orbiter (MPO) is a state of the art instrument for studies of the surface composition of Mercury. MERTIS is the first spaceborne push-broom spectrometer that allows mapping the Mercury's surface mineralogy in the diagnostic mid-infrared range.

The assessment of the optical performance by optical simulation and testing is presented. Moreover, the method for geometrical calibration of the thermal infrared imaging spectrometer and the fundamentals of this approach are discussed. The demonstrated results underpin the consistency between simulation and real data.

9608-5, Session 1

VIRTIS on Venus Express: retrieval of real surface emissivity at global scales

Gabriele E. Arnold, David Kappel, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany); Rainer Haus, Westfälische Wilhelms-Univ. Münster (Germany); Laura Tellez Pedroza, Univ. Potsdam (Germany); Giuseppe Piccioni, INAF - IASF Roma (Italy); Pierre Drossart, Observatoire de Paris à Meudon (France)

The extraction of surface emissivity data provides the data base for surface composition analysis and enables to evaluate Venus' geology. The Visible and InfraRed Thermal Imaging Spectrometer (VIRTIS) aboard ESA's Venus Express mission measured, inter alia, the nightside thermal emission of Venus in the near infrared atmospheric windows between 1.0 and 1.2 μm. These data can be used to determine information about surface properties on global scales. This requires a sophisticated approach to understand and consider the effects and interferences of different atmospheric and surface parameters influencing the retrieved values. In the present work, results of a new technique for retrieval of the 1.0 – 1.2 μm – surface emissivity are summarized. It includes a Multi-Window Retrieval Technique (MWT), a Multi-Spectrum Retrieval technique (MSR), and a detailed reliability analysis. The MWT bases on a detailed radiative transfer model making simultaneous use of information from different atmospheric windows of an individual spectrum. MSR regularizes the retrieval by incorporating available a priori mean values, standard deviations as well as spatial-temporal correlations of parameters to be retrieved. The capability of this method is shown for selected examples (surface target areas). Implications for geologic investigations are discussed. Based on these results the work draws conclusions for future Venus surface composition analyses on global scales using spectral remote sensing techniques. In that context, requirements for observational scenarios and instrumental performances are investigated, and recommendations are derived to optimize spectral measurements on Venus' surface studies.

9608-6, Session 1

Development of a mast or robotic arm-mounted infrared AOTF spectrometer for surface moon and mars probes *(Invited Paper)*

Oleg Korablev, Andrei Y. Ivanov, Space Research Institute (Russian Federation); Yurii K. Kalinnikov, VNIIFTRI (Russian Federation); Alexei Shapkin, Space Research Institute (Russian Federation); Sergei N. Mantsevich, Lomonosov Moscow State Univ. (Russian Federation) and Space Research Institute (Russian Federation); Anna A. Fedorova, Alexander V. Kiselev, Space Research Institute (Russian Federation)

A pencil-beam infrared AOTF spectrometer for context analyses of the surface in the vicinity of a planetary probe or a rover is being developed. One application is the ISEM (Infrared Spectrometer for ExoMars) instrument to be deployed on the mast of ExoMars Rover planned for launch in 2018. A very similar instrument LIS (Lunar Infrared Spectrometer) is planned to be flown on Russian Luna-25 (Luna Globe Lander) and Luna-27 (Luna Resource Lander) missions in 2018 and 2020 respectively. On these landers the instrument will be mounted at a robotic arm (Luna-25) or at a dedicated mast (Luna-27). The instrument covers the spectral range of 1.15–3.3 ?m with the spectral resolution of ~20 cm-1. The spectral range is selected to characterize the mineralogy; the long-wave bound allows to assess the hydration of the regolith on the Moon, and offers the ability to detect carbonates on Mars. The optical scheme includes entry optics, the TeO2 AOTF, and a Peltier-cooled InAs detector. To cover the whole spectral range the AOTF is equipped with two piezotransducers. At present the qualification prototype is being characterized. The instrument optics, and different aspects of its characterization, including low-temperature survival qualification will be described.

9608-7, Session 1

Middle-infrared echelle cross-dispersion spectrometer ACS-MIR for the ExoMars trace gas orbiter

Alexander Y. Trokhimovsky, Oleg Korablev, Space Research Institute (Russian Federation); Yurii S. Ivanov, Ivan I. Syniavsly, National Academy of Sciences (Ukraine); Alexander V. Stepanov, Lomonosov Moscow State Univ. (Russian Federation) and Space Research Institute (Russian Federation); Andrei Y. Titov, SKB IKI (Russian Federation); Tatiana O. Kozlova, Space Research Institute (Russian Federation); Andrei S. Patrakeev, Space Research Institute (Russian Federation) and Moscow Institute of Physics and Technology (Russian Federation); Pavel P. Moiseev, Astron Electronics (Russian Federation); Anna A. Fedorova, Space Research Institute (Russian Federation); Franck Montmessin, LATMOS (France)

The middle-infrared (MIR) echelle spectrometer is one channel of the Atmospheric Chemistry Suite (ACS) package dedicated for the studies of the Martian atmosphere on board ExoMars Trace Gas Orbiter (TGO) planned for launch in 2016. The MIR channel of ACS is a cross-dispersion echelle instrument dedicated to solar occultation measurements in the range of 2.2–4.4 ?m with the resolving power of ~50,000. MIR is dedicated to sensitive measurements of trace gases. The MIR channel consists of entry optics, an echelle spectrometer with a 140x250 mm grating and two-mirror collimator, a secondary steerable grating, and a cryogenically cooled MCT detector array with proximity optics. The spectrometer operates in high orders of diffraction, allowing to acquire ~20 orders at one detector frame, and to cover simultaneously ~300-nm spectral interval within the spectral range. The mechanism allows moving the secondary grating with a characteristic time of ~0.1 s, and the alternation of two positions is possible for a 1-s measurement cycle. This concept is novel for space application. The instrument is a complete block with power and data interfaces, and the overall mass of 12 kg.

At the moment of the abstract submission the integration of NIR protoflight model is being completed. The calibrated and tested instrument will be delivered to ESA in April 2015. The description of the instrument and the results of tests will be reported.

9608-8, Session 1

Near-infrared echelle-AOTF spectrometer ACS-NIR for the ExoMars trace gas orbiter

Alexander Y. Trokhimovsky, Oleg Korablev, Space Research Institute (Russian Federation); Yurii K. Kalinnikov, VNIIFTRI (Russian Federation); Anna A. Fedorova, Space Research Institute (Russian Federation); Alexander V. Stepanov, Lomonosov Moscow State Univ. (Russian Federation) and Space Research Institute (Russian Federation); Andrei Yu Titov, SKB IKI (Russian Federation); Andrei S. Patrakeev, Space Research Institute (Russian Federation) and Moscow Institute of Physics and Technology (Russian Federation); Ilya Dziuban, Space Research Institute (Russian Federation); Franck Montmessin, LATMOS (France)

The near-Infrared echelle-AOTF spectrometer is one channel of the Atmospheric Chemistry Suite (ACS) package dedicated for the studies

of the Martian atmosphere on board ExoMars Trace Gas Orbiter planned for launch in 2016. The near-infrared (NIR) channel of ACS is a versatile spectrometer for the spectral range of 0.7–1.6 ?m with a resolving power of ?20,000. The NIR channel is intended to measure the atmospheric water vapor, aerosols, airglows, in nadir, in solar occultation, and on the limb. The science goals of NIR are basically the same as for SPICAM IR channel presently in flight on board Mars Express ESA orbiter, but it offers significantly better spectral resolution. The instrument employs the principle of an echelle spectrometer with an acoustooptical tunable filter (AOTF) as a preselector. The same principle was employed in SOIR, working on Venus Express ESA mission in 2006-2014, and in RUSALKA, operated onboard ISS in 2009-2012. The NIR channel of ACS consists of entry optics, the AOTF, a Littrow echelle spectrometer, and an electrically cooled InGaAs detector array. It is a complete block with power and data interfaces, and the overall mass of 3.5 kg. At the moment of the abstract submission the integration of NIR protoflight model is being completed. The calibrated and tested instrument will be delivered to ESA in April 2015. The description of the instrument and the results of tests will be reported. A novel element, the AOTF in the converging beam will be also described, and some discussion on the echelle-AOTF scheme trade-offs will be presented.

9608-9, Session 1

Fourier-spectrometer ACS-TIRVIM for the ExoMars trace gas orbiter

Alexei V. Grigoriev, Boris E. Moshkin, Alexei V. Shakun, Oleg Korablev, Alexander V. Zharkov, Dmitry V. Patsaev, Fedor G. Martynovich, Andrei S. Kungurov, Oleg M. Sazonov, Igor A. Maslov, Alexander Santos-Skripko, Sergei A. Nenashev, Igor A. Stupin, Nikolai I. Ignatiev, Space Research Institute (Russian Federation)

The thermal-infrared (TIRVIM) is one channel of the Atmospheric Chemistry Suite (ACS) package dedicated for the studies of the Martian atmosphere on board ExoMars Trace Gas Orbiter (TGO) planned for launch in 2016. The TIRVIM channel is a 2-in. double pendulum Fourier-transform spectrometer for the spectral range of 1.7–17 ?m with apodized resolution of 0.2 to 1.6 cm?1, varying in function of the observing mode. TIRVIM is primarily dedicated to the monitoring of atmospheric temperatures and aerosol states in nadir, but also provides wide-range solar occultation measurements. TIRVIM optical scheme includes a sun periscope, a scanner, a blackbody simulator, an interferometer with a reference channel, and a detector with associated proximity optics. The whole spectral range is covered by one double pendulum interferometer with a KBr beamsplitter. The full (two-sided) maximal optical path difference (OPD) is 12 cm, allowing to reach an apodized spectral resolution of 0.2 cm?1. The custom-made MCT detector is cooled by a Stirling machine down to 65 K. The detector is sensitive at 1.7–17 ?m (germanium window), and it is determining the LW bound of the instrument. It is employed both in nadir and in solar occultation, allowing spectral resolution of 1.6 cm?1 and 0.2 cm?1, respectively. The instrument is a complete block with power and data interfaces, and the overall mass of 12 kg. At the moment of the abstract submission the integration of the TIRVIM protoflight model is being completed. The calibrated and tested instrument will be delivered to ESA in April 2015. The description of the instrument and the results of tests will be reported.

9608-10, Session 1

M-DLS laser and heterodyne IR spectrometer for studies of the martian atmosphere from ExoMars-2018 landing platform

Alexander V. Rodin, Moscow Institute of Physics and Technology (Russian Federation) and Space Research Institute (Russian Federation); Imant I. Vinogradov, Space Research Institute (Russian Federation) and Moscow Institute of Physics and Technology (Russian Federation); V. V. Barke, Space Research Institute (Russian Federation); O. V. Benderov, D. V. Churbanov, Artem Klimchuk, Moscow Institute of Physics and Technology (Russian Federation); Yu. V. Lebedev, Space Research Institute (Russian Federation); A. A. Pereslavtseva, Z. B. Seilov, V. S. Semenov, Moscow Institute of Physics and Technology (Russian Federation); Maxim V. Spiridonov, Prokhorov General Physics Institute (Russian Federation)

We present the concept of a compact, lightweight, multichannel laser spectrometer for in situ and remote sensing of the chemical and isotopic composition of the Martian atmosphere. The instrument M-DLS (Martian Diode Laser Spectrometer) has been accepted as part of science payload of the ExoMars landing platform, whose launch is planned in 2018. After delivery of ESA's rover to Mars' surface, the platform is expected to operate as an autonomous lander at least for one Martian year. A primary goal of the experiment is highly accurate measurements of composition and structure of the Martian atmosphere, with particular focus on water vapor, isotopic ratios, and methane. Measurements will be carried out on regular basis both in situ, using a sample of ambient atmosphere, and remotely, by direct Sun observations in heterodyne channel.

The instrument employs principles of diode laser spectroscopy, with tunable distributed feedback (DFB) lasers emission frequency being controlled by temperature stabilization and pumping current. Saw-like pumping current modulation results in ramping laser frequency so that it covers a particular spectral line. Laser radiation is partially put into optical cell filled by a sample of ambient air, with another portion of radiation passing through reference cell that provides feedback for frequency modulation control. Two types of lasers are used: diode DFB lasers for 1.6 ?m range, targeting H2O, H218O, CO2, 13CO2, and interband cascade lasers (ICL) for 2.76 ?m (H2O, HDO) and 3.3 ?m (CH4). For the sake of maximal sensitivity, an integrated cavity output spectroscopy (ICOS) technique is implemented by means of a multipass off-axis cell with highly reflective windows, which provides an effective optical path of ~1.5 km.

In addition to in situ analysis of atmospheric samples by means of classical laser spectroscoly technique, M-DLS instrument implements remote sensing of the atmosphere using optical heterodyning technique. Sunlight captured by a microtelescope is coupled in a single model optical fiber with local oscillator radiation taken from tunable diode and ICL lasers, whereas beat signal is analyzed by a digital data processing block. Heterodyne technique provides such unique measurements as Doppler sounding of winds in the free atmosphere and vertical profiling of water vapor in the lower scale height. Both in situ measurements with ICOS technique and remote sensing in heterodyne channel provide comparable sensitivity of methane detection, ~70 ppt.

With numerous engineering and photonic solutions implemented for the first time in space applications, M-DLS opens a unique opportunity to monitor Martian atmosphere with unprecedented accuracy. Further implications of this approach for future missions is a promising area of infrared instrument development.

9608-11, Session 2

Infrared sensor system using robotics technology for inter-planetary mission

Hiroki Hihara, NEC TOSHIBA Space Systems Ltd. (Japan) and The Univ. of Tokyo (Japan); Yousuke Takano, NEC Corp. (Japan); Junpei Sano, Kaori Iwase, NEC TOSHIBA Space Systems Ltd. (Japan); Satoko Kawakami, NEC Space Technologies, Ltd. (Japan); Hisashi Otake, Tatsuaki Okada, Japan Aerospace Exploration Agency (Japan); Ryu Funase, The Univ. of Tokyo (Japan); Jun Takada, Tetsuya Masuda, NEC Corp. (Japan)

Infrared sensor system is a major concern for inter-planetary missions in order to investigate the nature and the formation processes of planets and

asteroids. Since it takes long time for the communication of inter-planetary probes, automatic and autonomous functions are essential for provisioning observation sequence including the setup procedures of peripheral equipment. Robotics technology which has been adopted on HAYABUSA 2 asteroid probe provides functions for setting up onboard equipment, sensor signal calibration, and post signal processing. HAYABUSA2 was launched successfully in 2014 for the exploration of C class near-Earth asteroid 162173 (1999JU3). An optical navigation camera with telephoto lens (ONC-T), a thermal-infrared imager (TIR), and a near infrared spectrometer (NIRS3) have been developed for the observation of geology, thermo-physical properties, and organic or hydrated materials on the asteroid. ONC-T and TIR are used for those scientific purposes as well as assessment of landing site selection and safe descent operation onto the asteroid surface for sample acquisition. NIRS3 is used to characterize the mineralogy of the asteroid surface by observing the 3-micron band, where the particular diagnostic absorption features due to hydrated minerals appear.

Modifications were required in order to apply robotics technology for the probe, because the operation of satellites is different from standard robot operation environment. The major difference is time line consideration, because the standardized robotics operation software development system is based on event driven framework. The consistency between the framework of time line and event driven was established for the automatic and autonomous operation for HAYABUSA2.

9608-13, Session 2

Measurement of the speed of light from extraterrestrial sources *(Invited Paper)*

Jing-shown Wu, National Taiwan Univ. (Taiwan)

We first discuss the conventional measurements of the speed of light, which were performed before the early twentieth century. Only few utilized extraterrestrial light sources and obtained the results with large uncertainty, others used the local light sources and got quite accurate value, c. Recently science and technologies have advanced very much, which provides us a great opportunity to measure the speed of light from extraterrestrial sources. Here we propose a new concept by using the well-known value, c, as the reference to measure the speed of light from extraterrestrial sources. We design a modulator at the transmitter to modulate the rays from a local infrared light source and the extraterrestrial sources simultaneously into pulses which are received by a distant receiver. We use the infrared pulses as the reference and the trigger signal. We have a local white light travelling exactly along the path of the light from the extraterrestrial sources for calibration. We used Capella, Aldebaran, and Vega as the extraterrestrial sources. We compare the travel times of these starlight pulses and the white light pulses. It is found that the travelling times of Aldebaran and Capella pulses are longer than that of Vega pulses, where Aldebaran and Capella are moving away and Vega is approaching us. The results indicate that the speeds of lights from the extraterrestrial sources are different from the well-known value, c. We have analyzed the uncertainty of the results in details. The data obtained in 2010-2014 are quite consistent.

9608-14, Session 2

Stratospheric observatory for infrared astronomy (SOFIA): science, science instruments and observatory operations *(Invited Paper)*

Maureen L. Savage, SOFIA / USRA (United States)

The joint U.S. and German Stratospheric Observatory for Infrared Astronomy (SOFIA), project has been operating airborne astronomy flights from Palmdale, California since 2011. The observatory consists of a modified 747sp aircraft with a 2.5 meter telescope in the tail section. In addition to observing flights out of Palmdale, Ca. this airborne observatory has been able to take advantage of its mobility to observe in the southern hemisphere (New Zealand), to perform multi-wavelength observations of the Super Novae (SN 2014b) in 2014, and to intersect the track of a Pluto Occultation in the southern hemisphere just a few weeks prior to the New Horizons mission fly by of the planet in summer 2015.

Science results, observatory operations, current instrument status and participation in future instrument developments, over the lifetime of the observatory will be discussed.

9608-56, Session 2

A compact, lightweight and low cost laser heterodyne IR spectrometer for greenhouse gases and wind monitoring

Artem Klimchuk, Moscow Institute of Physics and Technology (Russian Federation); Alexander V. Rodin, Moscow Institute of Physics and Technology (Russian Federation) and Space Research Institute (Russian Federation); V. S. Semenov, O. V. Benderov, D. V. Churbanov, A. A. Pereslavtseva, Z. B. Seilov, Moscow Institute of Physics and Technology (Russian Federation)

Greenhouse gases (GHG), among which most important are CO2, CH4, and N2O, are subject to monitoring from spacecraft, in situ measurements, and ground-based remote observations. One of the problem limiting development of ground networks, such as TCCON, is relatively expansive and complex Fourier transform spectrometers used for GHG monitoring, and necessity of highly skilled personnel for their maintenance. We propose a compact, lightweight and low cost instrument that provides precise in situ GHG measurements by means of tunable diode laser spectroscopy technique (TDLS) and simultaneous spectroradiometric sounding of the atmospheric column. As local oscillators the instrument uses distributed feedback (DFB) diode lasers with precisely controlled radiation frequency, modulated by pumping current. Wavelengths in the range 1.6 – 1.65 mm are chosen, so that at least one unsaturated line of GHG is covered by each laser. LO frequency is ramping around the contour of a selected spectral line, and stabilized using an off-axis multipass reference cell. Radiation of Sun passed through the atmosphere is coupled with LO signal in a single mode optical fiber. Backend data treatment is reduced to digital square detection of a noise produced by phase-decoupled mixing of sunlight with LO. Not only the resulting spectral resolution ????-108 allows highly accurate measurements of GHG column, but also provides a unique opportunity to retrieve vertical profiles of some component and to estimate vertical profile of wind velocity up to 30-50 km. Due to relatively low cost of the instrument's production and maintenance, existing ground networks of GHG monitoring and sounding may substantially expanded, which in turn may result in new insight into climate change problem.

9608-15, Session 3

Dim object detection in cluttered scenes

Chris Agh, Matt Buoni, Toyon Research Corp. (United States)

In this paper, we discuss an algorithmic approach for exploiting temporal signatures in cluttered optical data for the purpose of detecting dim, stationary objects. The cluttered scene backgrounds are substantially more intense than focal plane array noise and temporal variations in signals from dim objects. As a result, clutter estimation and rejection algorithms are performed prior to implementing object detection schemes. Even then, stationary clutter leakage may have similar spatial characteristics to, and intensities that are more than an order of magnitude higher than, those of the stationary objects of interest. We discuss here an algorithm which was developed in a track-before-detect (TrbD) framework in order to overcome these challenges. The algorithmic approach will be presented as well as results showing low-latency detection of small, stationary objects with extremely low signal-to-clutter ratios (SCRs) in cluttered images.

9608-16, Session 3

Field results from investigating potential correlations between jet engine noise and plume dynamics in the hypertemporal infrared domain

Phillip M. Cunio, Reed A. Weber, Kimberly Knobel, Air Force Research Lab. (United States)

Following up on initial research presented at SPIE Optics + Photonics 2014, a theoretical analysis of jet engine infrared signatures and potentially-detectable characteristics of such signatures in the hypertemporal domain was used to define and carry out a systematic test campaign to detect and correlate these signatures with acoustic jet engine characteristics.

This paper describes the field campaign and its results. Test conditions and equipment are detailed, and field data is summarized. Analysis methods and results are also described, and conclusions are drawn about the correlated characteristics of temporal and acoustic signatures. Finally, follow-up work is proposed.

Detected hypertemporal signatures in association with acoustic signatures of jet engines can enable the use of a new domain in characterizing jet engine noise. This may in turn enable new methods of predicting or mitigating jet engine noise, which could lead to socioeconomic benefits for airlines and other operators of large numbers of jet engines.

9608-17, Session 3

Fractional intensity modulation of diffusely scattered light

John Kielkopf, Elijah Jensen, Univ. of Louisville (United States); Frank O. Clark, Spectral Sciences, Inc. (United States); Bradley Noyes, Wopeco Research (United States)

We report on model predictions of angular effects of fractional intensity modulation of light that is diffusely scattered from a vibrating surface, and compare these to experimental data for a few common materials. We show the predicted and observed effects of the time dependent properties of the BRDF of the material on detected fractional modulation. We suggest a few practical commercial applications of this type of measurement.

9608-18, Session 3

Remote optical interrogation of vibrations in materials inspection applications

Jason A. Cline, Ryan W. Penny, Bridget Tannian, Spectral Sciences, Inc. (United States); John Kielkopf, Univ. of Louisville (United States)

We report development of applications of remote sensing of vibration for purposes of nondestructive inspection of aerospace equipment. Remote sensing of vibration recently made headlines when it was shown that vibrations in video recorded with consumer-grade cameras can be detected and translated into audio [1]. Earlier and perhaps more quietly heralded were developments applying similar techniques to deduce structural health of bridges [2] and to survey spatial variation of materials properties [3], either by examining subtle but correlated in-scene motions that span many pixels, or through the influence of minuscule surface-normal deflections on the light reflected into the sensor. These passive stand-o? techniques have the potential to revolutionize routine inspections of mechanical and aerospace equipment by making remote vibration detection and analysis e?cient and a?ordable.

Given these observational technologies, the stand-o? inspection of materials is enabled by the principle that the propagation of vibration through a mechanical medium, as observed from its surface, depends on its internal properties. This fact is routinely employed in laser doppler velocimetry (LDV) inspections; for test articles such as sti? flat plates, the behavior is specifically described by Lamb waves. LDV interrogates one or multiple points directly for position and velocity, while in contrast the passive approach is indirect through the surface's bidirectional reflectance distribution function and its parameters (ambient light distribution, camera bistatic angle). While this external dependence might at first seem like an inconvenience, it provides the opportunity for the lighting and camera bistatic angle to be manipulated to produce the best measurement.

We present progress developing software and measurement protocols that are designed to detect and locate local anomalies in subsurface material properties (i.e., damage) as well as material boundary conditions (i.e., attachment along a bond line). We will start with our own experimental measurements on carbon-epoxy composite and other test articles and describe model data agreement.

SPIE 9219, Infrared Remote Sensing and Instrumentation XXII], 92190G, Society of Photonics and Instrumentation Engineers (2014). doi:10.1117/12.2064366.

9608-19, Session 3

Remote optical detection of ground vibrations

Robert M. Shroll, Spectral Sciences, Inc. (United States); Benjamin St. Peter, Univ. of Massachusetts Amherst (United States); Steven C. Richtsmeier, Bridget Tannian, Spectral Sciences, Inc. (United States); Elijah Jensen, John Kielkopf, Univ. of Louisville (United States); Wellesley E. Pereira, Air Force Research Lab. (United States)

We present progress being made in the passive optical remote detection of ground surface vibration. With proper design, minute seismic surface waves may be captured using remote visible imagery. We identify factors that determine the degree of modulation, including the angle of illumination from the surface normal, the angle of scattering to the sensor, the surface tilts with respect to these directions, and for an uncollimated source, the distance of the source to the surface. We also note the dependence of the modulation on surface texture and contrast, which may be treated with a bidirectional reflectance distribution function to represent the behavior of a complex surface with unresolved structure. We present an analysis of the optical measurements of ground surfaces performed during the passing of nearby trains with discussions of the hardware, software, and detection clutter sources. The field measurements are put into context with laboratory measurements, theory, and simulation.

9608-20, Session 3

Comparative analysis of IR images degraded by lossy compression techniques

Reed A. Weber, Air Force Research Lab. (United States); William A. Toussaint, Boston College (United States)

This work addresses image degradation introduced by lossy compression techniques and the effects of such degradation on signal detection statistics for applications in fast-framing (>100 Hz) IR image analysis. As future space systems make use of increasingly higher pixel count IR focal plane arrays,

data generation rates are anticipated to become too copious for continuous download. The prevailing solution to this issue has been to compress image data prior to downlink. While this solution is application independent for lossless compression, the expected benefits of lossy compression, including higher compression ratio, necessitate several application specific trades in order to characterize preservation of critical information within the data. Current analyses via standard statistical image processing techniques following tunably lossy compression algorithms (JPEG2000, JPEG) allow for detection statistics nearly identical to analyses following standard lossless compression techniques, such as Rice and PNG, even at degradation levels offering a greater than twofold increase in compression ratio. Ongoing efforts focus on repeating the analysis for other tunably lossy compression techniques while also assessing the relative computational burden of each algorithm. Current results suggest that lossy compression techniques can preserve critical information in fast-framing IR data while either significantly reducing downlink bandwidth requirements or significantly increasing the usable focal plane array window size.

9608-21, Session 4

GOSAT operation beyond the designed lifetime *(Invited Paper)*

Hiroshi Suto, Akihiko Kuze, Kei Shiomi, Masakatsu Nakajima, Japan Aerospace Exploration Agency (Japan)

To observe the global column concentration of carbon dioxide (CO2) and methane (CH4) from space, the Greenhouse gases Observing SATellite (GOSAT) was launched on January 23, 2009, and has started the operational observation. Thermal and Near Infrared Sensor for Carbon Observation – Fourier Transform Spectrometer (TANSO-FTS) has been continuously measuring CO2 and CH4 distributions globally, and supporting the global carbon cycle elucidation. It is important to monitor the greenhouse gases in long time period with same quality. During 6 years operational periods, GOSAT passed the designed lifetime, which is 5 years, and some components report the change of characteristic in-orbit. The pointing mechanism, which has a capability of change a line of scene both of along track and cross track, is equipped on GOSAT. Usually, the settling time of pointing mechanism is less than 0.4sec. Recently, it is slightly longer than the expected one. To keep the quality of spectra from TANSO-FTS and try to ambitious observation plan, the pointing mechanism is switched to the backup one. The initial check with the backup pointing mechanism present that the settling time is less than 0.4 sec and the spectra is good quality. After the radiance, spectral and geometric characterization, the dataset with the backup pointing mechanism will be released. The latest status of instrument, ground processing and observation plan with refreshed pointing mechanism will be presented.

9608-22, Session 4

High resolution near infrared imaging spectrometer in CO2 detection

Xueqian Zhu, Lei Ding, Xinhua Niu, Shanghai Institute of Technical Physics (China)

The overview of the related performance indexes of the hyperspectral atmospheric CO2 imaging system has been described above. In the paper, we design and simulate a feasible imaging system, which has a big opposite aperture and small IFOV (instantaneous field of view), it results in good performance. A planar reflection grating structure is selected for beam splitting, and an appropriate image sensor is chose to cooperate to carry out the demonstration system which aims at the 1606nm channel, and with it we conduct several experimental measurements both in the library and external field. The experiment results show that, in the near-infrared band of 1606 nm, the spectral resolution of this demonstration system can reach 0.1nm at a bandwidth of 30nm. It can verify the imaging system meets the requirements of acquiring high precise CO2 data, show us, meanwhile, which aspects should be reconsidered or improved. The future work is to implement the whole tri-channel system obeying the scheme and ameliorate it gradually.

9608-23, Session 4

Fast calculation of scattered radiance in multispectral imagery simulation

Xiaoyu He, Xiaojian Xu, BeiHang Univ. (China)

Two-stream approximation is most commonly used to calculate scattered radiance in multispectral imagery simulation. However, the typical two-stream approximation is based on the plane-parallel atmosphere assumption and may not be used in the radiance calculation of scenario involving the earth-limb region without modification. In addition, if the two-stream approximation is used to calculate the scattered radiance pixel-by-pixel, it is very time-consuming to generate a large-scaled image. As a consequence, an imagery simulation model needs to make a compromise between the computational accuracy and speed.

In this paper, a fast calculation method of scattered radiance for scenario involving both earth surface region and earth-limb region is proposed. The single scattering equation of typical two-stream approximate is adapted to compute atmospheric radiative transfer under the spherical-parallel atmosphere assumption. With specified atmospheric profiles, spectral band and observation geometry, a 2-D matrix of the scattered radiance varying with incident zenith angle and viewing zenith angle are then calculated. Finally, the earth disk images are generated in different spectral bands by interpolating the calculated radiance matrices. Numerical simulation results of multispectral earth disk images for space-based earth observation sensors are presented to demonstrate the usefulness of the proposed technique for high fidelity scene where both the earth surface and the earth-limb regions are observed.

9608-24, Session 4

Radiometric calibration of the ECOSTRESS signal chain

William R. Johnson, Andre Wong, Colin Donahue, Robert Smythe, Jet Propulsion Lab. (United States)

ECOsystem Spaceborne Thermal Radiometer Experiment on Space Station (ECOSTRESS) is a NADIR viewing instrument that will provide 5 thermal infrared spectral bands across a wide swath (53 degrees) at high spatial resolution (38m along track x 64m cross track). The instrument and payload will be delivered to the JSC in early 2017 and installed on the Japanese experiment module (JEM) sometime after. ECOSTRESS will be the first thermal infrared multi-spectral imager on the space station.

The signal chain is unique, since it uses a custom read out integrated circuit (ROIC) which operates 32 output channels at high speed. This fast readout allows the high resolution spatial sampling when coupled to a telescope and scan mirror assembly. The scan mirror operates at a constant scan speed. Part of the work in completing the total dynamic signal chain was to confirm the velocity motion of the scan mirror is smooth to within a fraction of the time frame it takes to scan a ground sample distance (GSD). The signal chain uses flexible links for connectors and the noise performance was compared with an existing test dewar. It was found the system signal chain could provide enough isolation to equal the test results in the original dewar assembly. This allows the proper signal to noise performance as required.

9608-26, Session 5

Verification of gallium as thermal calibration reference in space *(Invited Paper)*

Gail E. Bingham, Shane Topham, Harri Latvikoski, Utah State Univ. Research Foundation (United States); Igor Podolski, Institute of Biomedical Problems (Russian Federation)

During long space flights, precision temperature calibration may be a

requirement that cannot be maintained using available temperature sensors. Examples of future systems that may require on-orbit calibration are missions like those of the Voyager spacecraft which may have left the solar system after being launched in 1977, the New Horizons mission to Pluto which was launched in 2006, or remotely controlled plant growth chambers to support human exploration on Mars. Another critical application is the orbital sensors that will monitor global climate change during the next few decades. Climate change remote sensors require low drift rates for their onboard thermometry, which are unattainable currently without some means of on-orbit recalibration. Phase change materials (PCM) such as those that make up the International Temperature Standard (ITS-90) standards are seen as the most reliable references on the ground and could be good candidates for orbital recalibration references.

We have been developing miniaturized phase change references for recalibration of long-duration space sensors. To determine if microgravity would affect the phase transitions of Phase change materials we recently conducted an experiment with the ITS-90 material (gallium) on the ISS. We compared gallium's phase change temperature with earth based measurements. The Ga melt cell was launched to the ISS in November 2013 returned to Kazakhstan in March 2014. The experiment measured melts and freezes of Ga using repeated six hour cycles. This presentation will provide a comparison of the preflight, flight and post flight data.

9608-27, Session 5

Absolute spectroradiometric calibration of standard stars

John T. Woodward, Keith R. Lykke, Claire E. Cramer, Gerald T. Fraser, National Institute of Standards and Technology (United States)

The SI traceability of astronomical measurements depends on measurements of Vega made at Mount Hopkins in the 1970's. More recent observations of Vega have shown it is oriented pole on, rapidly rotating, and surrounded by a debris disk. This leads to questions about its suitability as a standard star. Additionally, advances in both radiometry and measurements and modeling of the atmosphere over the past 30 years lead us to conclude that a new campaign to make SI traceable measurements of absolute, top-of-the-atmosphere, stellar spectroradiometry with <1% uncertainty is in order.

There are two primary challenges facing such a campaign: making low-uncertainty, traceable radiometric measurements in the field as opposed to a laboratory setting, and accounting for atmospheric absorption. Preliminary measurements of Vega indicate we can achieve sufficient signal to noise with a 4" refractive telescope coupled to a fiber fed spectrometer. By viewing a calibrated source ~80 meters away the system can be calibrated in the field. By observing the target star as it moves through a range of airmass from ~1.5 to 3.0, a variant of a Langley analysis is used to assess and correct for light lost in the atmosphere. The radiometric performance of the system is currently being tested in the Telescope Calibration Facility (TCF) at NIST. Methodologies and results from a preliminary campaign at Mount Hopkins will be presented.

9608-28, Session 5

Optical gratings and grisms: developments on straylight and polarization sensitivity improved microstructures

Peter Triebel, Torsten Diehl, Tobias Moeller, Carl Zeiss Microscopy GmbH (Germany); Alexandre Gatto, Alexander Pesch, Lars Erdmann, Matthias Burkhardt, Alexander Kalies, Carl Zeiss Jena GmbH (Germany)

Optical diffraction gratings are mainly influencing the optical performance of spectral imaging devices and optical spectrometers. Thus elements are designed and manufactured to the specific requirements of the imaging devices and optical spectrometers. The spectral sensing properties of spectral imaging devices and optical spectrometers are driven by the parameters spectral resolution and signal-to-noise ratio. The performance of diffraction gratings provides an initial way to improve instrumental resolution.

Over recent years, ZEISS has established and optimized a systematic manufacturing process to produce monolithic, real blazed gratings (transmission or reflection), based on a combination of holographic recording and ion beam etching together with in-house processing of high-end grating substrates.

This paper presents recent developments on the optical design and manufacturing process of real blazed monolithic gratings. Such microstructures can be applied on substrates having flat surfaces and curved surfaces such as spherical, aspherical or free-form shapes. In order to enhance the spectral resolution of a grating, the combination with a prism-like (Grism) acting substrate is a proven method. We report on a monolithically (Grism) approach for simulating and realizing such functionality.

The optical parameters of polarization sensitivity, efficiency and straylight are the key-parameters and will be discussed on recent manufactured gratings together with its potential for optimization.

Beside of the polarization sensitivity the improvements of low scattering gratings without having ghosts is one of the important parameter to improve to system performance of spectral imaging devices and optical spectrometers. The latest results of those improvements will be reported in this paper.

9608-29, Session 5

Payload system design for reducing size weight and power of a thermal infrared Earth resource monitoring instrument

Trent Newswander, Scott Hansen, Jed Hancock, Space Dynamics Lab. (United States)

An instrument for thermal infrared Earth resource monitoring has been designed to meet stringent Landsat heritage requirements with reduced size, weight and power (SWaP). Measurement of the land surface temperatures in two long-wave infrared bands provides Earth resource monitoring. These bands are especially valuable for monitoring water resources and water use.

Stringent radiometric and spatial resolution requirements drive the instrument design increasing SWaP. Specifically the stringent radiometric requirements require tight thermal management including multiple temperature zones and cryogenic operating temperatures. Furthermore radiometric requirements necessitate an on-board calibration system and strong straylight rejection. For spatial resolution, the ground sample distance and the relative edge response slope and edge extent requirements drive the aperture size of the optical telescope assembly.

Instrument subsystems including the focal plane module subassembly, optical telescope assembly, payload electronics, thermal management system and inflight calibration system have been studied, analyzed and conceptually designed to reduce overall instrument SWaP while still meeting all requirements. Reductions in SWaP make it possible for the instrument to fit on a small satellite bus. Since mission cost historically correlates well with mass and power on-orbit, it is expected that significant cost savings will result from the predicted SWaP reductions.

9608-30, Session 6

Optimal assimilation of advanced infrared and microwave sounding data for numerical weather prediction

Chian-Yi Liu, National Central Univ. (Taiwan); Chung-Chih Liu, Minghsin Univ. of Science and Technology (Taiwan); Tang-Huang Lin, National Central Univ. (Taiwan); Agnes H.

N. Lim, Univ. of Wisconsin-Madison (United States)

Regional numerical weather prediction (NWP) model can handle high spatial and temporal resolutions forecast when the initial fields are in a reliable state nowadays. The meteorological satellite could provide critical data when convectional observation is not available. The advanced infrared and microwave sounders, such as the hyperspectral infrared AIRS and microwave AMSU onboard NASA's Aqua satellite, could retrieve the best estimation of atmospheric thermodynamic state, which will help to improve the initial fields through data assimilation technique. However, the soundings from these two sensors have some limitation when use both of them. The AIRS could provide fine spatial resolution data than AMSU. It is anticipated the spatial gradient could retrain in AIRS. However, AMSU could provide atmospheric profiles in cloudy sky. In this presentation, we would like to discuss the optimal assimilation of both advanced infrared and microwave sounding data for improving the numerical weather prediction. It demonstrates a better handling of both hyperspectral infrared and microwave sensors data could provide positive impact over than use either sensor alone.

9608-31, Session 6

Temperature resolution enhancing of commercially available IR camera using computer processing

Vyacheslav A. Trofimov, Vladislav V. Trofimov, Lomonosov Moscow State Univ. (Russian Federation)

We use new developed computer code for computer processing of the images captured by commercially available IR camera . Using this code we demonstrate clearly changing of human body skin temperature induced by water drinking. We discuss also another experiments dealing with the person which is drinking or eating. We believe that we increase ten times (or more) the temperature resolution of such camera

Shown phenomena are very important for the detection of forbidden samples and substances cancelled inside the human body using non-destructive control without using X-rays. Early we have demonstrated such possibility using THz radiation. Carried out experiments can be used for solving of counter-terrorism problem and for medicine problems.

9608-32, Session 7

Efficient visible through SWIR focal plane MTF measurement

Neil R. Malone, Raytheon Co. (United States)

Raytheon Vision Systems (RVS) has developed an efficient method to measure MTF on Visible through SWIR small pixel FPAs. The measured data was obtained using an advanced but low cost test set with sub μm target projection on the FPA and real time display of the LSF as the slit is walked through focus. The test set is commercially procured, maintained and calibrated, provides target and filter holders and a light source. The analysis summary includes references from simplified MTF published analysis tools and a list of artifacts to be aware of when measuring MTF. The SWIR detectors have Mesa structure geometry for improved MTF performance and the Visible has state of the art crosstalk control to provide excellent MTF performance. The modeled data is compared to measured tilted slit MTF measured data and shows close agreement.

9608-33, Session 7

Modern multispectral, ground, airborne and space digital focal plane technology

Neil R. Malone, Raytheon Co. (United States)

Modern focal plane (FPA) Read Out Integrated Circuitry (ROIC) includes on FPA analog to digital conversion, multiple gain states and well sizes, and allows the hybridization of multiple detector material types with tunable Visible through LWIR performance. These revolutionary design capabilities support the next generation ground, airborne and space applications. Responsiivity, NEI and linearity Performance data is shown for SWIR, MWIR and LWIR focal planes that meets or exceeds the best performance possible using the same ROIC while hybridized to a different cutoff detector material.

9608-34, Session 7

Advancements in large-format SiPIN hybrid focal plane technology at Raytheon

Sean P. Kilcoyne, Neil Malone, Raytheon Co. (United States)

This paper presents Raytheon's recent advancements in the latest generation large format Hybrid CMOS/SiPIN focal planes. The current family of devices has very low read-noise ROICs, low detector dark current, operate with a 25 volt bias and deliver 50% mean response operability greater than 99.99%. The continuous improvement efforts in both ROIC and device processing have led to enhancements in improvements in device performance. Detectors with customized thicknesses and anti-reflective interfaces have demonstrated the ability to manipulate QE and MTF per design specifications. Improvements in the DBH hybridization capability have demonstrated 4 and 5μm pitch capability.

9608-35, Session 7

Lifetime evaluation of large format CMOS mixed signal infrared devices

Albert W. Linder, Raytheon Co. (United States)

New large scale foundry processes continue to produce reliable products. These new large scale devices continue to use industry best practice to screen for failure mechanisms and validate their long lifetime. The Failure-in-Time analysis in conjunction with foundry qualification information can be used to evaluate large format device lifetimes. This analysis is a helpful tool when zero failure life tests are typical. The reliability of the device is estimated by applying the failure rate to the use conditions. JEDEC publications continue to be the industry accepted methods.

9608-36, Session 7

Focal plane precision alignment, metrology, accuracy, knowledge and capability

Jay R. Neumann, Raytheon Co. (United States)

Focal plane alignment reduced pixel sizes and faster optical systems require enhanced precision methodology and stability. The increasing focal plane array sizes continue to drive the alignment capability. The Focal Plane flatness often requires flatness of 25 um range held over transition temperatures from ambient to cryogenic temperatures as well as maintained in an airborne or launch vibration. This paper addresses the challenge of the detector integration into the focal plane assembly, the methodology to reduce error terms, the incorporation of thermal shifts and co-registration of detectors.

The alignment methodology reduces the error terms by minimizing the measurement transfers and providing direct read options. Proper material selection using matched coefficient of expansion materials minimizes both the physical shift over temperature as well as lowering the stress induced into the detector. The co-registration of focal planes and /or slits can achieve submicron relative positioning capabilities by applying precision equipment interferometry and piezoelectric positioning stages. All measurements and characterizations maintain traceability to NIST standards. The metrology characterizes the equipment's accuracy, repeatability and precision of the measurements.

9608-37, Session 8

Cavity-enhanced AlGaAs/GaAs resonant tunneling photodetectors for telecommunication wavelength light detection at 1.3 μm *(Invited Paper)*

Andreas Pfenning, Fabian Hartmann, Fabian Langer, Sven Höfling, Martin Kamp, Lukas Worschech, Julius-Maximilians-Univ. Würzburg (Germany)

We demonstrate a cavity-enhanced photodetector at the telecommunication wavelength of ? = 1.3 μm based on a resonant tunneling diode (RTD). The cavity-enhanced resonant tunneling diode (RTD) photodetector consists of three integral parts: A Ga0.89In0.11N0.04As0.96 absorption layer that can be lattice-matched grown on GaAs and is light-active in the near infrared spectral region due to its reduced bandgap energy. An Al0.6Ga0.4As/GaAs double barrier RTD that serves as high gain internal amplifier of weak electric signals caused by the photo-generation of electron hole pairs within the GaInNAs absorption layer. An optical distributed Bragg reflector (DBR) cavity consisting of five top and seven bottom alternating GaAs/AlAs mirror pairs, which provides an enhanced quantum efficiency at the resonance wavelength. The samples were grown by molecular beam epitaxy and RTD mesa structures with diameters from 1 μm up to 12 μm were fabricated on the epitaxial layers. Ring-shaped Au-top-contacts ensure optical access and electric contact. The electro-optical properties of the RTDs were studied at room temperature. From the reflection-spectrum the optical resonance at ? = 1.29 μm was extracted. The current-voltage characteristics were studied in the dark and under illumination and a well-pronounced photo-response was found that is attributed to accumulation of photogenerated holes in the vicinity of the resonant tunneling structure. The maximum photocurrent was found at the optical resonance of 1.29 μm. At resonance, sensitivity up to S = 3.1 ? 10^4 A/W were observed and photocurrent up to several pA per incident photon was measured.

Modulation transfer function of infrared focal plane arrays *(Invited Paper)*

Sarath D. Gunapala, Sir B. Rafol, David Z. Ting, Alexander Soibel, Cory J. Hill, Arezou Khoshakhlagh, John K. Liu, Jason M. Mumolo, Sam A. Keo, Linda Hoeglund, Edward M. Luong, Jet Propulsion Lab. (United States)

Modulation transfer function (MTF) is the ability of an imaging system to faithfully image a given object. The MTF of an imaging system quantifies the ability of the system to resolve or transfer spatial frequencies. In this presentation we will discuss the detail MTF measurements of 1024x1024 pixels multi-band quantum well infrared photodetector and 320x256 pixels long-wavelength InAs/GaSb superlattice infrared focal plane arrays (FPAs). Broad-band (7.5-12?m) Quantum Well Infrared Photodetector (QWIP) detector array with progressively varying light coupling gratings based on GaAs/AlGaAs material is hybridized to 1024x1024 pixel format read out integrated circuit (ROIC). Nine types of light coupling gratings were used to optimize the light coupling in efficiency of the different regions of the FPA. We measured the horizontal and vertical MTFs of the FPA as a function of spatial frequency of all nine spectral bands. The experimentally measured Noise Equivalent Temperature Differences (NE?Ts) of the nine-band 1024x1024 FPA were spread from 12.1 – 13.8 mK with 300K background and f/2 cold stop at 40K FPA operating temperature. Long wavelength Complementary Barrier Infrared Detector (CBIRD) based on InAs/GaSb superlattice material is hybridized to recently designed and fabricated 320x256 pixel format ROIC. The n-type CBIRD was characterized in terms of performance and thermal stability. The experimentally measured NE?T of the 8.8?m cutoff n-CBIRD FPA was 18.6 mK with 300K background and f/2 cold stop at 78K FPA operating temperature. The horizontal and vertical MTFs of this pixel fully delineated CBIRD FPA at Nyquist frequency are 49% and 52%, respectively.

9608-39, Session 8

Alternative infrared and plasmonic materials: metal germanides and conductive oxides *(Invited Paper)*

Nima Nader, Air Force Research Lab. (United States) and College of Optical Sciences, The Univ. of Arizona (United States); Shivashankar Vangala, Joshua Hendrickson, Air Force Research Lab. (United States); William Streyer, Daniel Wasserman, Univ. of Illinois at Urbana-Champaign (United States); Kevin Leedy, David Look, Air Force Research Lab. (United States); Richard Soref, Univ. of Massachusetts Boston (United States); Justin Cleary, Air Force Research Lab. (United States)

In recent years, search for alternative infrared materials with applications in optics and plasmonic have been accelerated which in part is attributed to the poor performance and large losses of noble metals. Presented in this work are different classes of newly emerging materials with properties superior to that of conventional metals in applications suitable for infrared plasmonics and optics. Special emphasis has been placed in designed structures specific to sensing mechanisms.

Metal germanides are investigated as the first group of candidates in order to enable a CMOS-compatible group-IV based plasmonics technology. Different compositions were formed by electron beam evaporation of Ge and metal (Ni, Pd, Pt, Ta, and Ti) and annealing in a nitrogen purged furnace. Different characterization methods such as x-ray diffraction analysis (XRD) and x-ray photoelectron spectroscopy (XPS) are used to determine the material composition of the final films. Infrared (IR) ellipsometry is also used to determine the IR complex permittivity which is utilized to analytically determine basic plasmonic characteristics such as propagation loss and mode confinement for each composition.

Highly-doped gallium zinc oxide (ZnGaO) is also studied as a possible candidate for low-loss and widely broadband infrared material. In addition to material characterization and determination of optical constants, specifically designed 1D-grating and 2D-array structures are presented for investigation of plasmon mode excitation, extraordinary optical transmission, and light trapping. These designs can be tailored to the wavelengths of interest and utilized for capabilities in infrared sensing, enhanced sensitivity detection, signal processing, and communications.

9608-40, Session 8

Colloidal quantum dot materials for infrared optoelectronics

Susanna M. Thon, Johns Hopkins Univ. (United States)

Colloidal quantum dots (CQDs) are an attractive material for optoelectronic applications because they combine flexible, low-cost solution-phase synthesis and processing with the potential for novel functionality arising from their nanostructure. Specifically, the bandgap of films composed of arrays of CQDs can be tuned via the quantum confinement effect for tailored spectral utilization. PbS-based CQDs can be tuned throughout the near and mid-infrared wavelengths and are a promising materials system for photovoltaic devices that harvest non-visible solar radiation. The performance of CQD solar cells is currently limited by an absorption-extraction compromise, whereby photon absorption lengths in the near infrared spectral regime exceed minority carrier diffusion lengths in the bulk films. I will review several light trapping strategies for overcoming this compromise and increasing the efficiency of infrared energy harvesting. These include hierarchical geometric, nanophotonic, and plasmonic light trapping techniques, all of which enable photocurrents approaching the theoretical limits in sub-micron film thicknesses of the active material.

9608-41, Session 9

Quantum confined semiconductor nanocrystals for use in high efficiency: low cost solar energy conversion strategies *(Invited Paper)*

Matthew C. Beard, National Renewable Energy Lab. (United States)

Nanoscale systems as opposed to bulk or thin film versions of the same compounds exhibit some profoundly different properties and have dramatically changed the picture of how solar cells convert sunlight into free energy. In general there are two broad approaches based on nanostructures that are being explored for PV; (1) significantly reduce material usage and/or associated final costs; and (2) target PV approaches that have a higher limiting efficiency than that determined by the Shockley-Queisser analysis. One approach to higher limiting efficiencies is the process of multiple exciton generation (MEG) where absorption of high-energy photons can lead to the production of multiple electron-hole pairs that can contribute to an enhanced photocurrent in solar cells. We have studied this process in a variety of semiconductor nanostructures and find that MEG increases with quantum confinement. I will discuss the MEG characteristics needed in order to make the largest impact on solar energy conversion technologies. We have incorporated QDs into solar cells and are developing new chemistries that can increase PLQYs and improve PV performance. I will discuss our recent progress in QD solar cells

9608-42, Session 9

Limiting efficiencies of photo-detection and solar energy conversion via internal emission of hot electrons and hot holes *(Invited Paper)*

Svetlana V. Boriskina, Jiawei Zhou, Wei-Chun Hsu, Bolin Liao, Gang Chen, Massachusetts Institute of Technology (United States)

Photo-detection and solar energy harvesting via photon absorption in metal nanostructures and collection of photo-generated hot electrons via the internal photoemission have been recently actively explored as promising alternatives to conventional semiconductor-based detectors and energy converters. Metals such as Au were considered as candidates for gapless photon absorbers that are potentially capable of infrared photon detection and full solar spectrum harvesting. However, the energy conversion efficiencies demonstrated to date have been extremely low, although successful photo-detection experiments have been reported. In this talk, I will discuss the efficiency and responsivity limits for infrared detection and full-spectrum harvesting of solar light that can be achieved with traditional metals such as gold, and will also introduce some alternative materials that potentially offer comparable or superior performance. In particular, I will discuss the efficiency and responsivity limits for hot electron extraction via the use of cheap, abundant and lightweight carbon-based materials such graphite and graphene. Overall, a promising photoactive material should simultaneously offer (1) high broadband photon absorption, (2) slow hot electron decay, and (3) electron density of states that yields a sizeable population of hot electrons (or hot holes) with the energies high enough to be collected across the potential barrier.

9608-43, Session 9

Nanomembranes and soft fabrication methods for high performance, low cost energy technologies *(Invited Paper)*

Ralph G. Nuzzo, Univ. of Illinois at Urbana-Champaign (United States)

The fabrication of high performance integrated circuits provides examples of the most sophisticated manufacturing methods, as well as the most high performance materials, used in any area of modern technology. The advanced functional systems they provide are ones that are generally characterized by a massive integration of circuit elements within compact, rigid and essentially planar form factor devices. New means of fabrication and enabling nanomembrane materials are beginning to provide a set of means through which it is possible to lift these constraints—doing so in ways that both retain capacities for high (or altogether new forms of) performance while enabling new opportunities in technology. Our collaborative research here at the University of Illinois is providing form factors for devices with interesting but what had been to date difficult to realize features. Examples include: light weight, large area, high performance electronics, optics, and photonics; electrooptical systems with curvilinear shapes and capacities for accommodating demanding forms of mechanical flexure; new device form factors for use in sensing and imaging that integrate responsive materials in 3D with demanding nanometer design rules; functional biomaterials, and hybrid systems for lighting, energy storage, and photovoltaic energy conversion that provide a potentially transformational approach to supplant current technologies with high performance, low cost alternatives. Taken together, the results recent research and commercialization efforts illustrate important opportunities for exploiting advances in materials in synergy within additive and physical means of patterning and fabrication. In this lecture I will explore several exemplary applications taken from this work, and specifically highlight scalable approaches to high performance integrated systems for low cost photovoltaic energy conversion.

9608-44, Session 9

New concept to break the intrinsic properties of organic semiconductors for optical sensing applications *(Invited Paper)*

Wallace C. H. Choy, The Univ. of Hong Kong (Hong Kong, China)

The space charge limit (SCL) effect is a universal phenomenon in semiconductor devices involving light emitting diodes, solar cells, and photodetectors. Typically, the SCL will exist in the condition of (1) unbalanced hole and electron mobility; (2) thick active layer; (3) high light intensity or dense photocarriers (electrons and holes) generation; and (4) moderate reverse bias. Through the study of plasmonic organic solar cells, we will show metallic nanostructures go beyond their optical functions to control recombination, transport, and collection of photocarriers generated from active organic materials. Through spatially redistributing light absorption at the active layer, the proposed plasmonic-electrical concept is fundamentally different from the hot carrier effect where photocarriers are generated from metallic nanostructures. The new plasmonic-electrical effect not only lays a physical foundation but also upgrades electrical properties for semiconductor devices [1]. We will also design different device structures to investigate and demonstrated how plasmonic-electrical [2] and plasmonic-optical [3] effects can be used to enhance device performances such as improving the light absorption of solar cells, increasing emission efficiency of light emitting devices, reducing dark current and enhancing sensitivity of photodetector as well as intensifying the surface enhanced Raman scattering for biosensor applications. Besides the optical (plasmonic) resonances from metal nanostructure, we will also use metal nanostructures to demonstrate electrical resonance which can be used for bistable and memory devices [4]. Consequently, exploiting both plasmonic-optical and plasmonic-electrical effects via metallic nanostructures will open up a more flexible and integrated way to design high-performance optoelectronic nanodevices.

9608-45, Session 9

Hot electron detectors and energy conversion in the UV and IR *(Invited Paper)*

Jeremy N. Munday, Univ. of Maryland, College Park (United States)

Semiconductor materials are well suited for power conversion when the incident photon energy is slightly larger than the bandgap energy of the semiconductor. However, for photons with energy significantly greater than the bandgap energy, power conversion efficiencies are low. Further, for photons with energy below the bandgap energy, the absence of absorption results in no power conversion. In this talk, I will discuss our recent results in photon detection and power conversion of both high energy and sub-bandgap photons using hot carrier effects. For the absorption of high-energy photons, excited electrons and holes have excess kinetic energy, which results in the generation of hot electrons and holes. Energy is typically lost through a thermalization process between the carriers and the lattice. However, collection of carriers before thermaliztion allows for reduced power loss. We have recently shown that transparent conductor – insulator – metal structures can be used to collect these hot carriers. Further, for photons with energy below the semiconductor bandgap energy, no electrons and holes are generated; however, hot carrier collection is still possible when a Schottky junction is formed at the semiconductor-metal interface. I will also discuss our recent work in IR detection based on sub-bandgap photon absorption.

9608-46, Session 9

2D materials for photon conversion and nanophotonics *(Invited Paper)*

Volker J. Sorger, Mohammad H. Tahersima, The George Washington Univ. (United States)

Recent investigations of semiconducting two-dimensional (2D) transition metal dichalcogenides have provided evidence for strong light absorption relative to its thickness attributed to high density of states. Stacking a combination of metallic, insulating, and semiconducting 2D materials enables functional devices with atomic thicknesses. While photovoltaic cells based on 2D materials have been demonstrated, the reported absorption is still just a few percent of the incident light due to their sub-wavelength thickness leading to low cell efficiencies. Here we show that taking advantage of the mechanical flexibility of 2D materials by rolling a molybdenum disulfide (MoS2)/graphene (Gr)/hexagonal boron nitride (hBN) stack to a spiral solar cell allows for solar absorption up to 90%. The optical absorption of a 1 um-long hetero-material spiral cell consisting of the aforementioned hetero stack is about 50% stronger compared to a planar MoS2 cell of the same thickness; although the volumetric absorbing material ratio is only 6%. We anticipate these results to provide guidance for photonic structures that take advantage of the unique properties of 2D materials in solar energy conversion applications.

9608-47, Session 10

Photothermal effects, hot plasmonic electrons and plasmonic photochemistry in hybrid nanostructures for light harvesting in the visible and infrared intervals *(Invited Paper)*

Alexander Govorov, Ohio Univ. (United States)

We investigate the effects of generation of heat and hot plasmonic carriers in metal nanostructures. The problem of heat release from optically-excited plasmonic nanocrystals is treated classically [1,2] whereas the hot electron problem is calculated using the quantum mechanical approach based on the equation of motion for the density matrix [3-5]. The energy distribution of optically-excited plasmonic carriers is very different in metal nanocrystals with large and small sizes. In large nanocrystals, most excited carriers have very small energies and the electron distribution resembles the case of a plasmon wave in bulk. For gold nanocrystal with smaller sizes (less than 20nm), the energy distribution of hot carriers becomes flat and has a large number of carriers with high energy [3-5]. Therefore, smaller nanocrystals are preferable for injection of plasmonic carriers into semiconductors or into molecules on the surface. The physical reason for the above behavior is non-conservation of momentum in a nanocrystal. The geometry, type of metal, and orientation of the external electric field are important to obtain high quantum efficiencies of generation and injection of plasmonic electrons [3-5]. Other important properties and limitations: (1) Intra-band transitions are preferable for generation of energetic electrons and dominate the absorption for relatively long wavelengths (approximately >600 nm), (2) inter-band transitions efficiently generate energetic holes in the d-band of gold and (3) the carrier-generation and absorption spectra can be significantly different [3-5]. The d-band hole generation can be used for efficient plasmonic photochemistry [6]. The results obtained in this study can be used to design a variety of plasmonic nanodevices based on hot electron injection for photo-catalysis, light-harvesting, and solar cells.

Refractory plasmonic metal nitrides for infrared spectral region *(Invited Paper)*

Vladimir M. Shalaev, Purdue Univ. (United States); Urcan Guler, Nano-Meta Technologies, Inc. (United States); Alexander V. Kildishev, Alexandra Boltasseva, Purdue Univ. (United States)

The use of plasmonic effects over a broad range of electromagnetic spectrum has been a challenge over the first few decades of research due to limited number of available materials. Recently, the efforts in the area has been concentrated on identifying and examining new material classes as the building blocks for optical technologies over a broader electromagnetic spectrum. Transition metal nitrides attract attention as plasmonic materials in the visible and infrared spectral regions with optical properties resembling gold. As refractory materials, nitrides can withstand heat-induced physical phenomena as well as aggressive chemical environment. Adjustable dielectric permittivity of plasmonic nitrides allows for fine-tuning of optical properties for selected applications. In addition to favorable optical, physical and chemical properties, transition metal nitrides provide

CMOS- and bio-compatibility. In this talk, novel designs and concepts based on refractory plasmonic materials for infrared applications will be presented. Furthermore, light confinement at the nanoscale with refractory plasmonic antennas, spectral engineering of absorption and emission with subwavelength-thin metasurfaces, and the use of colloidal solutions for a variety of applications will be discussed.

9608-49, Session 10

Enhancing selectivity of infrared absorbers and emitters through quality-factor matching *(Invited Paper)*

Peter Bermel, Purdue Univ. (United States)

It has recently been proposed that designing selective emitters with photonic crystals (PhCs) or plasmonic metamaterials can suppress low-energy photon emission, while enhancing higher-energy photon emission. In this presentation, we will consider multiple approaches to designing and fabricating nanophotonic structures concentrating infrared thermal radiation at energies above a critical threshold. These are based on quality factor matching, in which one creates resonant cavities that couple light out at the same rate that the underlying materials emit it. When this quality-factor matching is done properly, emissivities can approach those of a blackbody, but only within a selected range of thermal photon energies. One potential application is for improving the conversion of heat to electricity via a thermophotovoltaic (TPV) system, by using thermal radiation to illuminate a photovoltaic (PV) diode. In this study, realistic simulations of system efficiencies are performed using finite-difference time domain (FDTD) and rigorous coupled wave analysis (RCWA) to capture both thermal radiation and PV diode absorption. We first consider a 2D molybdenum photonic crystal with a commercially-available silicon PV diode, which can yield TPV efficiencies up to 26%. Second, a 1D-periodic erbium aluminum garnet emitter with a gallium antimonide PV diode is presented, which can yield efficiencies up to 34%. Finally, a 2D tungsten photonic crystal with a 1D integrated, chirped filter can yield efficiencies up to 49.3%; however, the fabrication procedure is expected to be more challenging. The advantages and disadvantages of each strategy will be discussed, and preliminary room-temperature characterization measurements will be presented.

9608-50, Session 10

Passive radiative cooling of terrestrial surfaces below ambient under direct sunlight *(Invited Paper)*

Aaswath P. Raman, Linxiao Zhu, Shanhui Fan, Stanford Univ. (United States)

Cooling is a significant end-use of energy globally and a major driver of peak electricity demand. At night, electricity-free cooling below ambient air temperature has been demonstrated using a technique known as radiative cooling or night-sky cooling, where one uses a device exposed to the sky to radiatively emit heat to outer space through a transparency window in the atmosphere between 8-13 μm. Peak cooling demand however occurs during the daytime. Daytime radiative cooling below ambient under direct sunlight has not previously been achieved because sky access during the day results in heating of the radiative cooler by the sun.

In this talk, we first highlight the theoretical requirements necessary for daytime radiative cooling and discuss the need for a photonic approach. We then present results of the first experimental demonstration of daytime radiative cooling, where we achieve a temperature of nearly 5°C below the ambient air temperature under direct sunlight. Using a thermal photonic approach, we design and fabricate an integrated photonic solar reflector and thermal emitter consisting of 7 layers of HfO2 and SiO2 that reflects 97% of incident sunlight while emitting strongly and selectively in the mid-infrared atmospheric transparency window. Even when exposed to direct solar irradiance of greater than 850 W/m2 on a rooftop, the photonic radiative cooler achieves an average of 4.9°C below ambient air temperature over, and has a cooling power of 40.1 W/m2 at ambient. Finally, we will briefly comment on related work on using thermal photonic approaches to passively maintain solar cells at lower temperatures, while maintaining their solar absorption.

9608-51, Session 10

Nanophotonics for energy applications *(Invited Paper)*

Marin Soljacic, Massachusetts Institute of Technology (United States)

Nanophotonics provides superb opportunities for tailoring the flow of light. This way, many novel physical phenomena can be enabled, as well as many important functionalities for novel energy applications. In order to make these phenomena useful for large systems, large-area nano-fabrication techniques have to be successfully implemented. In this talk, I will present some of our recent theoretical and experimental progress in exploring these opportunities.

9608-52, Session PWed

Estimation of urban surface emissivity based on sub-pixel classification of Landsat 8 imagery

Erdeneshoo Orolmaa, Mongolian Univ. of Science and Technology (Mongolia); Sanjaa Tuya, MUST (Mongolia); Jadamba Batbayar, Mongolian Univ. of Science and Technology (Mongolia)

Abstract— Information about the spatial distribution of urban surface emissivity is essential for surface temperature estimation. The latter is critical in many applications, such as estimation of surface sensible and latent heat fluxes, energy budget, urban canopy modeling, bio-climatic studies and urban planning. This study proposes an estimation of urban surface emissivity, which is primarily based on spectral mixture analysis. The urban surface is assumed to consist of three fundamental land cover components, namely vegetation, impervious and soil that refer to the urban environment. Due to the complexity of the urban environment, the impervious component is further divided into two land cover components: high-albedo and low-albedo impervious. Emissivity values are assigned to each component based on emissivity distributions derived from the Landsat 8. Following the proposed method, by combining the fraction of each cover component with a respective emissivity value, an overall emissivity for a given pixel is estimated. The methodology is applicable to visible and near infrared satellite imagery, therefore it could be used to derive emissivity maps from most multispectral satellite sensors. The proposed approach was applied to Landsat 8 multispectral data for the city of Ulaanbaatar, Mongolia. Emissivity, as well as land surface temperature maps in the spectral region of 10.6 - 11.2 ?m (Landsat8 band 10) and 11.5-12.5 (Landsat8 band 11) were derived.

9608-53, Session PWed

Intelligent image processing for vegetation classification using multispectral Landsat data

Stewart Rene Santos Arce, Jorge Luis Flores Nuñez, Guillermo Garcia-Torales, Univ. de Guadalajara (Mexico)

We propose an intelligent computational technique for analysis of vegetation imaging, which are acquired with multispectral scanner (MSS) sensor. This work is focuses on intelligent and adaptive artificial neural network (ANN) methodologies that allow segmentation and classification of spectral remote sensing (RS) signatures, in order to obtain a high resolution map, in which we can delimit the wooded areas and quantify

the amount of combustible materials present into these areas. This could provides information to prevent fires and deforestation of wooded areas. The spectral RS input data, acquired by the MSS sensor, are considered in a random propagation remotely sensed scene with unknown statistics for each Thematic Mapper (TM) band. Once performing high-resolution reconstruction and adding these spectral values with neighbor pixels information from each TM band, we can include contextual information into an ANN. The biggest challenge in conventional classifiers is how to reduce the number of components in the feature vector, while preserving the major information contained in the data, especially when the dimensionality of the feature space is high. Preliminary results show that this method is a promising and effective spectral method for segmentation and classification in RS images acquired with MSS sensor.

9608-54, Session PWed

Neurotransmitter identification Raman spectroscopy for sleep deprivation assessment

Raul Beltran, Univ. de Guadalajara (Mexico); G. Lopez-Armas, Ctr. de Enseñanza Técnica Industrial (Mexico); Guillermo Garcia-Torales, Verónica María Rodríguez Betancourtt, Jorge L. Flores, Univ. de Guadalajara (Mexico)

Insomnia is one of the most common sleep disorders in humans. Due to ethical and methodological difficulties involved in human research we use mice models to evaluate what has been called Paradoxical Sleep Deprivation (PSD) which is selective for Rapid eye movement (REM) sleep. By other hand brainstem cholinergic neurotransmission is involved in the generation and maintenance of rapid eye movement (REM) sleep. There is strong evidence that pontine cholinergic and cholinoceptive neurons, interacting in coordination, trigger and maintain REM sleep. So in this work we measure the content of acetylcholine and serotonin by Raman spectrophotometry and western blot technique in cerebral cortex.

9608-55, Session PWed

Terrestrial photograph spectral band analysis for shape and material by using remote sensing technique

Abdulrazak A. Mohammed, Ali Izzadin, Salahaddin Univ.-Hawler (Iraq)

One of the remote sensing technique is Photogrammetric grid system , which is the generation of processing system with an efficiency developed based on photographic spectral analysis and computer cluster parallel processing and the new development of photogrammetry has been applied on the traditional sample " Citadel -Gate of Erbil city".

9608-57, Session PWed

Recent progress of microscale IR thermography: a practical application to visual thermal analysis and microscale heat transfer

Junko Morikawa, Tokyo Institute of Technology (Japan)

As the performance of thermal detectors of infrared focal plane arrays (IR FPA), called micro-bolometers, has been developed, a practical application of microscale infrared (IR) thermography to a quantitative visual thermal analysis becomes more realistic with a smaller pixel pitch and larger pixel numbers of FPA obtaining NETD 50 mK and pixel size smaller than 17 ?m, with reducing the cost.

In order to realize the mobile type quantitative micro-scale thermography apparatus using a micro-bolometer, we presented the following proposals;

1. An achromatic lens design for a micro-scale image,
2. A video signal superimposed for the real time emissivity correction,
3. A pseudo acceleration of a timeframe.

The mobile type apparatus for a quantitative micro-scale thermography using a micro-bolometer was developed based on the above original techniques. The total size of the instrument was designed as it was put in the 17 cm x 28 cm x 26 cm size carrying box.

Our next stage is to expand the recent technique to the spectroscopic thermal imaging and the flying spot method.

Conference 9609: Infrared Sensors, Devices, and Applications V

Wednesday - Thursday 12–13 August 2015
Part of Proceedings of SPIE Vol. 9609 Infrared Sensors, Devices, and Applications V

9609-1, Session 1

Semi-insulating GaAs and Au Schottky barrier photodetectors for near-infrared detection (1280 nm)

Ahmad I. Nusir, Yahia Makableh, Omar Manasreh, Univ. of Arkansas (United States)

Schottky barriers formed between metal (Au) and semiconductor (GaAs) can be used to detect photons with energy lower than the bandgap of the semiconductor. In this study, photodetectors based on Schottky barriers were fabricated and characterized for detection of light at wavelength of 1280 nm. The device structure consists of three gold fingers with 1.75 mm long and separated by 0.95 mm, creating an E shape while the middle finger is disconnected from the outer frame. When the device is biased, electric field is stretched between the middle finger and the two outermost fingers.

The device was characterized by measuring the current-voltage (I-V) curve at room temperature. This showed low dark current on the order of 10^-10 A, while the photocurrent was higher than the dark current by four orders of magnitude. The detectivity of the device at room temperature was extracted from the I-V curve and estimated to be on the order of 4.2x10^10 cm.Hz^0.5.W^-1 at bias voltage of 5 V. The step response of the device was measured from time-resolved photocurrent curve at 5 V bias with multiple on/off cycle. From which the average recovery time was estimated to be 0.63 second when the photocurrent decreases by four orders of magnitude, and the average rise time was measured to be 0.897 second. Furthermore, the spectral response spectrum of the device exhibits a strong peak at wavelength of 1280 nm, which is attributed to the internal photoemission of electrons above the Schottky barrier formed between Au and semi-insulating GaAs.

9609-2, Session 1

Dependence on the depth of the arsenic implant in planar P+-on-n SWIR HgCdTe infrared detectors

Jonathan Schuster, U.S. Army Research Lab. (United States) and Boston Univ. (United States); Roger E. DeWames, Corbin Co. (United States); Enrico Bellotti, Boston Univ. (United States); Priyalal S. Wijewarnasuriya, U.S. Army Research Lab. (United States)

Recently there has been significant interest in utilizing planar P+-on-n HgCdTe detectors for applications in the short-wave infrared (SWIR) spectral band with detector cutoff wavelengths from 2.2-2.5 microns. Such cutoff wavelengths are well beyond the optimal cutoff wavelength of the closest competing technology which is InGaAs on InP. A key design feature of the Arsenic implanted planar P+-on-n HgCdTe detector design is the depth of the Arsenic implant. Normally, these detectors are designed such that the Arsenic implant extends into the narrow-gap absorber layer. This is done to facilitate the collection of photo-carriers from the absorber layer to the contact; however, this also results in a higher dark current. Alternatively, the implant could be designed such that it resides solely in the wide-gap cap layer. The detector performance is now especially dependent on the following sensitivity parameters: implant depth, layer doping, valence band offset between the narrow- and wide-gap layers, lifetime (specifically Shockley-Reed-Hall) and detector bias. The dark current and quantum efficiency due to these sensitivity parameters is determined by performing simulations using the finite element method which simultaneously solves the carrier continuity and Poisson equations on a finite element grid. The simulations reveal that by properly designing the depletion region the implant can be confined to the wide-gap cap layer, without reducing the quantum efficiency at small reverse bias. This is due to the significantly smaller valence band offset in HgCdTe, compared to InGaAs, which does not substantially prevent the collection of photo-carriers from the absorber to the contact.

9609-3, Session 1

Compositional control of the mixed anion alloys in gallium-free InAs InAsSb superlattice materials for infrared sensing

Heather J. Haugan, Frank Szmulowicz, Gail J. Brown, Krishnamurthy Mahalingam, Air Force Research Lab. (United States); Susan L Bowers, Air Force Research Lab (United States)

The objective of this work is to establish the molecular beam epitaxy (MBE) growth processes that can produce the high quality InAs/InAsSb type-II superlattice (SL) materials tailored for the maximum Auger suppression for a band gap of 207 meV. To accomplish this goal, several series of growth optimization studies were performed using a SL structure of 77 Å InAs/35 Å InAs0.7Sb0.3 to refine the MBE growth process and optimize growth parameters. Experimental results demonstrated that the SL structure we have chosen for the studies can produce an intended energy band gap, which is an important for the infrared sensing. However, there are other growth factors that also impact material properties of the SL materials. Since compositional control of the mixed anion alloys is essential to create the high quality strain-free SL structure that meets a specific wavelength requirement, the precise control of antimony composition was demonstrated through systematic study series by manipulating Sb/As flux ratios and deposition temperature. Optimization results are reported in the context of comparative studies on the influence of the deposition temperature on the crystalline quality and antimony composition performed under a variety condition of Sb/As flux ratios, InAs growth rates, and arsenic cracking temperatures. A quantitative analysis of the lattice strain, performed at the atomic scale by aberration corrected transmission electron microscopy, provided valuable information about compositional gradient at the InAsSb and the InAs layers, which was important for optimizing the mixed anion conditions.

9609-4, Session 1

An InGaAs p-i-n photodiode focal plane array with 360 degree field of view and 100% external quantum efficiency

Dejiu Fan, Kyusang Lee, Stephen Forrest, Univ. of Michigan (United States)

InGaAs focal plane arrays (FPAs) provide excellent performance for shortwave infrared (SWIR) range imaging. However, these SWIR FPAs have a planar structure, requiring complex and costly optical systems to reduce aberration while having only a limited field of view (FOV). Achieving a very wide FOV with a simplified optical system is possible if the image sensor arrays are made flexible to conform to the focal plane of the lens system. Here, we develop a method to transfer a thin-film InGaAs p-i-n photodiode FPA from its rigid and bulky InP substrate to a flexible and light-weight Kapton substrate using a combination of epitaxial lift-off (ELO) and cold-weld bonding technologies. Using these methods, we demonstrate a flexible 8 ? 100 detector FPA, which can be transformed into a cylinder to provide 360 degree FOV with ~99% fabrication yield. The array exhibits very high (~100%) external quantum efficiency (EQE) with a relatively thin InGaAs active layer by employing an integrated rear-side metal reflector that acts as a light trap. Under -1V bias, EQE = 82%, 99%, and 88% with a 5% estimated error at wavelengths of 980nm, 1300nm, and 1550nm, respectively. We also demonstrate 360 degree awareness of the array by imaging a rotating laser beam. These results suggest that flexible thin-film InGaAs p-i-n photodiode

FPAs can have improved performance compared to conventional substrate-based arrays. The unique features of this FPA integrated on the flexible or conformal structure provides a practical path for many imaging applications that will be discussed.

9609-5, Session 1

High-speed and high-saturation-current Si/Ge uni-traveling-carrier photodetector

Chong Li, Beijing Univ. of Technology (China)

A Ge-on-SOI uni-traveling carrier (UTC) photodetector was reported for high-power high-speed applications. The performances, in terms of dark-current, photocurrent responsivity and 3-dB bandwidth, were characterized for analog and coherent communications applications. The responsivity was 0.165 A/W at 1550 nm. The detector with a 15?m-diameter demonstrated an optical bandwidth of 10 GHz at -5V for 1550nm and dark current of 58nA at -1V. The -1dB compression photocurrent at 13GHz under -6V was about 16.2mA, the RF output power came to be 3.7 dBmw.

9609-6, Session 1

Enhancement of electron-injection detector performance by their special three-dimensional-geometry

Vala Fathipour, Hooman Mohseni, Northwestern Univ. (United States)

Sensitive short-wavelength infrared (SWIR) detectors with ultra-low noise levels and high signal-to-noise ratios are largely beneficial to a wide range of applications including astronomy, optical coherence tomography, and LIDAR. Absence of internal amplification in the mainstream InGaAs p-i-n detectors with extremely low noise levels, places stringent conditions on the read-out integrated circuit (ROIC) noise levels. Thus, a detector with a high internal amplification in addition to a low noise level could allow for ultimate sensitivity. Electron-injection detectors are based on a new single photon detection mechanism and address both above criterion. The large amplification in the detector takes advantage of the special three-dimensional geometry of the device that uses a large-scale absorbing volume and a small-scaled injector.

We have systematically studied the effect of the three-dimensional geometry on electron-injection detector's characteristics. Two different detector geometries were fabricated: Devices with same size injector and absorber diameters (type-A geometry) and devices with a smaller injector than the absorber diameters (type-B geometry). Analytical expressions were derived for the detector optical-gain to explain the significance of scaling the injector with respect to the absorber. Experimental measurement data together with our developed analytical model, confirm that the type-B device presents a larger optical-gain: ~ ten-times smaller injector area than the absorber, results in more than ten-times improvement in the optical gain. Furthermore, dark current of the type-B device is an order of magnitude lower than that of a type-A device with a similar mesa size.

9609-7, Session 1

Sensitivity advantage of using electron-injection detectors in ultra high speed 1060nm swept-source optical coherence tomography

Vala Fathipour, Hooman Mohseni, Northwestern Univ. (United States)

Optical coherence tomography (OCT) has recently become a powerful tool for non-invasive tomographic imaging in transparent and turbid specimens. Swept-source optical coherence tomography (SS-OCT) is emerging as one of the best methods within the OCT family as it has enabled higher frame-rate imaging, increased signal-to-noise ratio (SNR) and resolution.

Balanced detection is a commonly used detection method for suppression of the relative intensity noise (RIN) in SS-OCT systems. With today's swept-source lasers ~ 20-25 dB common-mode-rejection is needed by the balanced-detection method to reach shot noise limited SNR. A detector with no excess-noise-factor and with an internal amplification would be able to reach the shot-noise-limited performance at lower reference powers and reduce the RIN contribution. This would ultimately enable shot-noise-limited performance with a single detector, reducing the OCT system complexity and cost.

Electron-injection detectors are a new class of detectors with high internal avalanche-free amplifications (~2000 at -3V) together with an excess-noise-factor of unity. These characteristics make electron-injection detectors a potential candidate for an OCT system. To characterize the electron-injection detector for OCT application, we used a coupler to simultaneously send the interference signal to both the electron-injection detector and a commercial p-i-n detector. Despite the larger system input noise for the electron-injection detector, as a result of probing of the device, the internal-gain of the device results in SNRs in excess of 20 dB higher than a commercial p-i-n detector at measurement frequency of 22 MHz. Although the current device is not optimized for high speed, but even at the highest beating frequency of 250 MHz, 10 dB higher SNR was measured

9609-8, Session 1

A 16.4?m InGaAs/InAlAs quantum cascade detector

Shenqiang Zhai, Junqi Liu, Fengqi Liu, Zhanguo Wang, Institute of Semiconductors (China)

Very long wave infrared (VWIR) photodetectors, covering the spectral range from 14 to 20?m, are needed for a variety of space applications, such as atmospheric temperature profile and pollution monitoring, infrared astronomy and satellite mapping. However, the infrared detectors for this range are often limited to high dark current and low work temperature. As an alternative solution, quantum cascade detectors (QCDs), a new type of photovoltaic QWIPs, operating without bias are presented. They have clear advantages on the absence of dark current, low background noise, and high operation temperature. Therefore QCD is a very competitive technology for applications in very long wave range. In a QCD, the photon-generated electrons transferred from one period to another based on a carefully designed extraction cascade, which is adapted to the longitudinal optical (LO) phonon energy. However, for very long wave detection, only few cascade steps, namely quantum well (QW)/barrier pairs, are permitted due to the small detetction energy. This will induce strong coupling between adjacent active well ground states and the associated large noise current. In this work, we present a very long wave InGaAl/InAlAs quantum cascade detector operating at 16.4?m grown by solid source molecular beam epitaxy based on miniband based electron transport mechanism. The addition of miniband can suppress leakage current and increase device resistance, overcoming the challenge in constructing QCDs for very long wavelength detection. At 15K, we observed a responsivity of 10.6mA/W and a Johnson noise limited detectivity of 1.8?1010 Jones at 16.4?m.

9609-9, Session 1

Characterization on Geiger-mode operation of deep diffused silicon APDs

Erik B. Johnson, Xiao J. Chen, Mickel McClish, Richard Farrell, James F. Christian, Radiation Monitoring Devices, Inc. (United States)

Avalanche photodiodes (APD) manufactured at RMD are fabricated using deep diffusion processes, resulting in a thick reach-through APD with excellent performance characteristics. These include a high quantum efficiency (>50% for visible photons) and low excess noise (F ~ 2). Due to the structure of the APD, the devices have very low junction capacitance

(~0.7pF/mm2). These devices have been made as squares or hexagons on the order of 2-4" dimensionally and require >1000 V for operation. Due to the high operating bias, studies on the Geiger behavior were dismissed, yet this structure provides unique capability to improve upon existing silicon solid-state photomultipliers. The low capacitance is conducive to developing large-area devices, and the large drift region allows for charge steering toward the high breakdown field region. These results provide initial data on the performance characteristics of RMD's APDs when operated in Geiger mode. Due to the thickness of these devices, they provide a high gain-bandwidth product for near IR single photon counting. A small area (~1 mm2) APD was biased beyond the reverse bias breakdown voltage (~1640 V at -20 C), where the device showed typical Geiger-mode behavior with a low dark count rate (<1 kHz at an excess bias of 1 V). Data on the responsivity for different incident positions on the device area will be presented, as well as a measure of the efficiency as a function of excess bias beyond the breakdown voltage.

Determining the electrical mechanism of surface resistivity property of doped polyvinyl alcohol (pva) and pyroelectric properties of polyvinylidene difluoride (pvdf) films

Matthew E. Edwards Sr., Jemelia Polius, Padmaja Guggilla, Afef Janen, Michael Curley, Alabama A&M Univ. (United States)

Previously, we reported measurements of the temperature dependent surface resistivity of multi-wall carbon nanotube doped Polyvinyl Alcohol (PVA) thin films. In the temperature range from 22 0C to 40 0C, with a humidity control environment, we found the surface resistivity to decrease initially but to rise as the temperature continues to increases. Correspondingly, we have measured the temperature dependence of similarly doped PVDF thin films, as well, for their pyroelectric effect. While the physical mechanism of the pyroelectric phenomenon in thin films is better determined, that is not the case for surface resistivity of such films. Here, we address this concern by reporting the electrical mechanistic phenomena that contribute to surface resistivity of doped PVA thin films, and give resistivity surface effect detectivity D* and other relevant quality factor quality factor as sensors. Regarding pyroelectric effects of doped PVDF thin films, we give materials Figure of Merit for the values for our measurements. In addition, pyroelectric infrared sensors fundamentals, detector designs, unique and innovative techniques are presented. Finally, we report temperature dependent measure of surface resistivity measurements of single-wall carbon nanotube doped PVA thin film in comparison to that of the above multi-wall doped PVA thin films

9609-11, Session 2

Analytical model of avalanche photodiode based on "low-high-low" type heterostructure with separate absorption and multiplication regions

Viacheslav A. Kholodnov, Institute of Radio Engineering and Electronics (Russian Federation); Mikhail S. Nikitin, JSC "Shvabe-Photodevice" (Russian Federation); Igor D. Burlakov, Orion Research-and-Production Association (Russian Federation)

Traditional way to describe operation of avalanche photodiodes (APD) including avalanche heterophotodiodes with separate absorption and multiplication regions (SAM AHPD) is based on numerical calculation of well-known integral relations and it is very laborious. Traditional approach is not pictorial and very difficult in use for solving related problems. Our problem is calculation of tunnel current in SAM AHPD based on direct band semiconductors. In previous work, we have proposed analytical approach for description of SAM AHPD operation. Approach includes analytical expressions for avalanche breakdown electric field of p-n heterostructure and primary band-to-band tunnel current I(tun) in it, which defines minimum noise level of SAM APD based on direct band semiconductors. Main result obtained in previous consideration is strongly non-monotonic dependence I(tun) with minimum type extremum on dopant concentration N in multiplication layer. However, with increasing N, electric field at metallurgical boundary of p-n junction increases, that narrowing differential between coefficients of impact ionization of electrons and holes. This, in turn, increases avalanche noise-factor F. Therefore, to provide simultaneously low density of tunnel current and low value of avalanche noise-factor should be used heterostructure of "low-high-low" type. In such structures wide-gap layer consists of two sub-layers. First sub-layer, adjacent to metallurgical boundary of p-n junction is rather thick and low doped (up to i - type), and second layer, bordered with light absorber, is thin and heavily doped. Doping of light absorber can be mid-level.

9609-12, Session 2

Band structure and semiconductor to semimetal transition in InAs/GaSb nanostructure mid-infrared detector superlattice

Abderrazak Boutramine, Abdelhakim Nafidi, Driss Barkissy, Abdelkrim Hannour, Ahmed Saba, Thami El Gouti, Univ. Ibn Zohr (Morocco)

We report here theoretical investigation of the electronic properties for InAs (d1=25 Å)/GaSb(d2=25 Å) type II superlattice at 300 K with an experimental valence band offset ?=570 meV. Using the envelope function formalism, we calculated the energy E(kz) and E(kp), respectively, in the direction of growth and in plane of the superlattice. We studied the effect of the InAs layer thickness d1,?, and temperature on the band gap Eg (?)= E1-HH1, correspond to the optical transition of carriers from heavy-hole HH1 to conduction E1 bands, at the center ? of the first Brillouin zone. When d1 increases, the energy E(d1, ?, 300 K) shows that the band gap decreases to zero at d1c=61 ? accusing a semiconductor to semimetal transition and become negative with a semimetallic conduction behavior. In our case, d1=25 Å and Eg (?, 300K) = 230 meV. With increasing ? the band gap increases, presents a maximum of 600 meV at ?=-38.4 meV and switch from being positive to negative accusing a semimetallic conduction after ?c =920 meV. In the investigated temperature range, the cut-off wavelength 4.3 ?m ≤ ?c ≤ 5.4 ?m situates this sample as mid-wavelength infrared detector

(MWIR). These results agree well with the experimental data reported in literature.

9609-13, Session 2

Indirect-direct gap transition and electronic bands properties of GaAs/AlAs nanostructure superlattice for near infrared detection at room temperature

Driss Barkissy, Abdelhakim Nafidi, Abderrazak Boutramine, Hicham Charifi, Abdellatif Elanique, Ali Khalal, Univ. Ibn Zohr (Morocco)

We report here calculations of the electronic bands properties of GaAs(d1)/Ga1-xAlxAs(d2) for x=1 type I superlattice performed in the envelope function formalism as a function of the well layer thickness d1, the valence band offset ? at room temperature. The transition indirect to direct band gap, of (GaAs)m/(AlAs)4 SLs consisting of m GaAs monolayers (ML) and 4 ML of AlAs with 3 ≤ m ≤ 11 ML, takes place near m=5. The calculated fundamental band gap Eg (?)=E1-HH1 correspond to the optical transition of carriers from heavy-hole HH1 to conduction E1 bands. When the offset ? increases, this gap increases to a maximum near 1765 meV at ?=451 meV. After, it decreases parabolically. For each well thickness d1, the gap increases with the ratio d2/d1. For each ratio d2/d1, when d1 increases the gap decreases to the gap of GaAs (1424 eV at 300 K) for infinite d1. On the other hand, we have studied the temperature dependence of the direct band gap (m=9) of the GaAs (d1=2.52 nm)/AlAs (d2=1.16 nm) superlattice in the range of 6 K to 300 K. Eg decreases with temperature. Therefore, when d1 increases from 2 Å to 50 Å, Eg decreases and the corresponding cut-off wavelength ?c increases. These results are in agreement with the photoluminescence excitation (PLE) measurements of Lendentsov et al for a Kane energy Ep= 22.7 eV. In the investigated temperature range, the cut-off wavelength is 674 nm ≤ ?c ≤ 709 nm situates this sample as near infrared device.

9609-14, Session 3

Fabrication of resonator-QWIP FPA by inductively coupled plasma etching and projection printing

Jason N. Sun, Kwong Choi, Kimberley Olver, U.S. Army Research Lab. (United States)

Resonator-Quantum Well Infrared Photo detectors (R-QWIPs) are the next generation of QWIP detectors that use resonances to increase the quantum efficiency (QE). In order to improve thermal sensitivity, integration time, and operating temperature, a theoretical optimization of R-QWIPs has been performed. For 25 micron pitch, 10 Me- integrated charge, F/2 optics, and 9.2 micron cutoff, NETD can be 19 mK at Tint = 1.43 ms and T = 77 K. For 6 micron pitch, 6.8 Me- integrated charges, and F/1 optics, NETD = 19 mK at 4.0 ms and 77 K. To achieve the expected performance, the detector geometry must be produced in precise specification. In particular, the height of the diffractive elements (DE) and the thickness of the active resonator must be uniformly and accurately realized to within 0.05 ?m accuracy and the substrates of the detectors have to be removed totally to prevent the escape of unabsorbed light in the detectors. To achieve these specifications, two optimized inductively coupled plasma (ICP) etching processes are developed. Using these etching techniques, we have studied single detectors and fabricated FPAs with pixel pitches from 6 to 30 microns and formats from 256 x 256 to 1920 x 1080. Both contact and step and repeat projection systems were used to pattern the wafers. The detail of the FPA fabrication and their characteristics will be presented

9609-15, Session 3

High temperature operation In1-xAlxSb infrared focal plane

Yanqiu Lv, Luoyang Institute of Electro-Optical Equipment (China); Junjie Si, Xiancun Cao, Liang Zhang, Zhengyu Peng, Jiaxin Ding, Xiaolei Zhang, Luoyang Optoelectro Technology Development Ctr. (China); Valeriy Reobrazhenskiy, Institute of Semiconductor Physics (Russian Federation)

A high temperature operation mid-wavelength 128*128 infrared focal plane arrays (FPA) based on low Al component In1-xAlxSb was presented in this work. In1-xAlxSb materials were grown on InSb (100) substrates using MBE technology, which was confirmed by XRD and AFM analyses. We have designed and grown two structures with and without barrier. The pixel of the detector had a conventional PIN structure with a size of 50?m*50?m. The device fabrication process consisted of mesa etching, side-wall passivation, metallization and flip-chip hybridization with readout integrated circuit (ROIC), epoxy backfill, lap and polish. Diode resistance, imaging, NETD and operability results are presented for a progression of structures that reduce the diode leakage current as the temperature is raised above 80K, compared with a basic pin structure presented previously. These include addition of a thin region of InAlSb to reduce p-contact leakage current, and construction of the whole device from InAlSb to reduce thermal generation in the active region of the detector. An increase in temperature to 110K, whilst maintaining full 80K performance, is achieved. The responsivity spectra, I-V curves and blackbody current responsivity were measured at different temperature. Quantum efficiency, Pixel operability of the detector, non-uniformity, and the mean NETD values of the FPAs were measured at 110K. This gives the prospect of significant benefits for the cooling systems, including, for example, use of argon in Joule-Thomson coolers or an increase in the life and/or decrease in the cost, power consumption and cool-down time of Stirling engines by several tens of percent.

9609-16, Session 3

All optical modulator based on silicon resonator

Meir Danino, Moshe Sinvani, Zeev Zalevsky, Liron Bidani, Oded M. Baharav, Hadar Pinhas, Bar-Ilan Univ. (Israel)

In this paper we present an all-optical silicon modulator, where a silicon slab (450 μm) thick is coated on both sides to get a Fabry-Perot resonator for laser beam at wavelength of 1550nm. Most of the modulators discussed in literature, are driven by electrical field rather than by light. We investigate new approaches regarding the dependence of the absorption of the optical signal on the control laser pulse at 532 nm having 5nm pulse width. Our silicon based Fabry-Perot resonator increases the intrinsic c-Si finesse to >10, instead of the uncoated silicon with natural finesse of 2.5. The improved finesse is shown to have significant effect on the modulation depth using a pulsed laser. A modulation of 12dB was attained. The modulation is ascribed to two different effects - The Plasma Dispersion Effect (PDE) and the Thermo-Optic Effect (TOE). The PDE causes increase in the signal absorption in silicon via the absorption of the control laser light. On top of that, the transmission of the signal can decrease dramatically in high finesse resonators due to change in the refractive index due to TOE. The changes in the signal's absorption coefficient and in the refractive index are the result of incremental change in the concentration of free carriers. The TOE gives rise to higher refractive index as opposed to the PDE which triggers a decrease in the refractive index. Finally, tradeoff considerations are presented on how to modify one effect to counter the other one, leading to an optimal device having reduced temperature dependence.

9609-17, Session 3

Design of ultra-thin metallic grating based circular polarize for near infrared

DeJiao Hu, Ping Wang, Lin Pang, Sichuan Univ. (China)

The controlling of the polarization, which is crucial in applications such as signal sensing and processing, has attracted lots of attention. In this paper, we propose an ultra-thin metallic grating based circular polarizer, which can convert any polarization into circular polarization. The ultra-thin metallic grating, which is thinner than the skin depth and is half transparent for transverse electric (TE) wave, holds for high reflection for transverse magnetic (TM) incident wave. This anomaly is attributed to the Localized surface plasmon resonance (LSPR) of a single nano-strip in the grating. We found that the grating also has anomalous modulation property for the phase of transmission coefficient for TM illumination, which can be utilize to control the phase difference between TM and TE transmitted waves and realize a quarter-wave plate. Meanwhile, a linear polarizer formed by silicon grating is applied, ensuring that the light wave arriving the quarter-wave plate is linear polarization. The angle between the metallic grating wire and the silicon grating wire is designed so that the output wave behind the metallic grating is of specific circular polarization. The designing includes two steps. Firstly, realizing a quarter-wave plate with metallic grating. Secondly, optimizing the parameters of the silicon grating to ensure that the effective wavelength range contains the operation wavelength of the quarter-wave plate. We use COMSOL Multiphysics to calculate the phase difference between TM and TE transmitted waves from the ultra-thin metallic grating and choosing the parameters for the silicon grating. Our results show that the circular polarizer can convert any polarized into designed circular wave.

9609-18, Session 3

Comparison of a liquid crystal display and MEMS deformable mirror for adaptive optics compensation in a flood illuminating system

José Luis Magaña-Chávez, Sandra E. Balderas-Mata, Univ. de Guadalajara (Mexico); Gustavo Ramírez-Zavaleta, Luis Gabriel Valdivieso-González, Eduardo Tepichín-Rodriguez, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

Adaptive optics (AO) has been used in the last decades to compensate the aberrations of the atmosphere as well as those of the eye, i.e., static and dynamic aberrations. In ophthalmic instruments this technique has been used to improve the lateral resolution of the retinal images. Unfortunately, Deformable Mirror devices are still quite expensive. Recently, Liquid Crystal Display (LCD) devices has been analyzed to perform the compensation task because, these are less expensive; however, they need to be characterized to perform the aberration compensation task. In this work the comparison of the performance of a Liquid Crystal Display and a MEMS deformable mirror acting as adaptive optics devices in a flood illuminating fundus camera system is presented.

9609-26, Session PWed

Angle deviation correction for symmetric slant edges in linear imaging sensor MTF measurement

Ho-Lin Tsay, Ting-Ming Huang, Instrument Technology Research Ctr. (Taiwan)

Linear imaging sensors used in space instruments and industrial applications need a proof in various functions such as response linearity, signal-to-noise ratio, response non-uniformity, and modulation transfer function (MTF). For MTF test in imaging sensors, a tilted edge pattern was used to measure MTF in cross sensorline direction of these linear imaging sensors. Angle of tilting edge was demonstrated to be in certain range. And with knowledge of tilting angle, one can measure MTF curve convergently for different angles. In practice, we design one single tilting angle for measurement and develop signal processing algorithm for this specific angle. A misalignment between projected pattern and sensorline in relative orientation lead angle variation and therefore alter measuring result deriving by this algorithm. In this poster, we demonstrate the evolution of measuring result at different tilting angles, and development in correction of measuring result for angle misalignment.

9609-27, Session PWed

Study on electron escaping mechanism of multi-alkali photocathode in the Super Gen. II image intensifier

Xiao Feng Li, North Night Vision Technology Group Co., Ltd. (China)

By measuring the multi-alkali cathode spectral reflectance and transmittance of super gen.?image intensifier, the spectral absorption was obtained through calculating by the energy conservation law. Results shows that the multi-alkali cathode spectral absorption has a long wavelength absorption limit of 915 nm. During the electronic transition process of multi-alkali cathodes after the absorption of a photon, the energy increases of transition electron is less than the energy of the incident photons, i.e. there is an “energy loss”. The higher the photon energy and the higher transition electron’s energy level are, the greater the energy loss is. After Na2KSb cathode film of super gen.? image intensifier was activated by Cs, the peak wavelength of the fluorescence is shift toward blue, i.e. “blue shift” phenomenon was occurred. This indicated that transition electron energy levels of Na2KSb cathode film was promoted because of surface Cs activation.

9609-28, Session PWed

The fiber grating strain sensor using in high temperature environment

Qing Shi, Zhoulu Sun, Dongli Wang, Qingsong Chen, Jiachen Ning, Beijing Research Institute of Telemetry (China)

Fiber grating strain sensors often work in the high-temperature environment in many special industries. The temperature is even higher than 400 Celsius degrees.An increase in temperature corresponds to thermal expansion of the measured materials. The high temperature impacts not only the sensing element of the fiber grating sensor, but also the properties of the other materials in the fiber grating sensor except the sensing element. Moreover, the installation of the fiber grating strain sensor which need to work under high temperature become complicated. Fiber grating strain sensors getting the measurement precisely in the high temperature environment need several special designs.

Through lots of experiments, the influential factors impacted by the temperature are studied, and the fiber grating strain sensor working in the high temperature has been presented. Especially, we introduce the approaches and notices to design this kind of sensors.

9609-29, Session PWed

Welding pool measurement using thermal array sensor

Chia Hung Cho, Yi Chen Hsieh, Hsin Yi Chen, Industrial Technology Research Institute (Taiwan)

Selective laser melting (SLM) is an additive manufacturing (AM) technology that uses a high-power laser beam to melt metal powder in chamber of inert gas. Melting pool was formed by using laser irradiation on metal powders which then solidified to consolidated structure. In a selective laser melting process, the variation of melt pool affects the yield of a printed three-dimensional product. For three dimensional parts, the border conditions of the conductive heat transport have a very large influence on the melt pool dimensions. Therefore, melting pool is an important behavior that affects the final quality of the 3D object. To meet the temperature and geometry of the melting pool for monitoring in additive manufacturing technology. In this paper, we proposed the temperature sensing system which is composed of infrared photodiode array, band-pass filter, dichroic beam splitter and focus lens. Since the photodiode array look at the process through the 2D galvanometer scanner and f-theta lens, the temperature sensing system can be used to observe the melting pool at any time, regardless of the movement of the laser spot. In order to obtain a wide temperature detecting range, 100 °C to 2500 °C, the radiation from the melting pool to be measured is filtered into a plurality of radiation portions, and since the intensity ratio distribution of the radiation portions is calculated by using black-body radiation.

9609-30, Session PWed

Photothermal deflection of laser beam as means to characterize thermal properties of biological tissue: numerical study

Enoch Gutierrez-Herrera, Univ. Nacional Autónoma de México (Mexico) and Ctr. de Ciencias Aplicadas y Desarrollo Tecnológico (Mexico); Celia A. Sánchez Pérez, Carlos A. García-Cadena, Ctr. de Ciencias Aplicadas y Desarrollo Tecnológico (Mexico) and Univ. Nacional Autónoma de México (Mexico)

In the world, chronic diseases account for 60% of the rate of mortality. Chronic liver disease and cirrhosis (i.e. liver fibrosis) were the twelfth leading cause of death in 2010 in the U.S.A. Fibrosis refers to the accumulation of fibrous scar tissue, which is predominantly collagen. The gold standard of diagnosis for liver fibrosis continues to be biopsy sample and its corresponding histology assessment. A non-subjective and early diagnostic technique may improve clinical outcome by decreasing morbidity in patients and reducing medical costs. The build-up of collagen in the extracellular matrix of liver results in changes in density and thermal properties of tissue. We proposed to use the optical beam deflection method (OBDM) for characterization of tissue thermal properties. In this work, we evaluate numerically the feasibility of using the photothermal deflection of a laser beam that traverses a thermo-optic material in contact with liver to quantitate changes in thermal conduction. The ultimate goal is to develop an optical-integrated sensor for thermal characterization of tissue. We used the finite-difference method to model the heat transfer in liver for different fibrosis stages and to determine the refraction index gradient within an acrylic slab because of heat conduction. The response required from the optical-integrated sensor is assessed by calculating the photothermal deflection angle using ray trace. Numerical study shows the potential of the OBDM for developing an optical-integrated sensor as non-subjective diagnostic technique for liver fibrosis.

9609-19, Session 4

Remote road surface sensor using a single-wavelength light source

Chi Ruan, Yuntao Wang, Xi'an Institute of Optics and Precision Mechanics (China)

Road surface conditions are very important for traffic safety. According to statistics, the ratio of traffic accidents that occur on icy, wet and dry road surface is 4.2:1.6:1. A remote road surface sensor was developed in this paper which could identify the surface condition including dry, icy and wet, that may be vital for preventing traffic accidents. Traditionally, multiple wavelength light from 900nm to 1700nm would be used for road face sensor, which system is complex and expensive. Such non-invasive sensor based on detecting the reflection of road surface illuminated by a single wavelength light source with 1550nm wavelength is proposed. Under different surface conditions, the power of diffuse reflection varied with incident angle was plotted in curves, and by comparing the shape, the road condition could be identified. The relationship between the detected light power and incident angle has been studied, both theoretically and experimentally. The experiment and simulation results show that the curve of received power vs. incident angle possesses certain pattern under certain road surface conditions, when incident angle is within the range of zero to seven point three degree. By using these patterns of curve, the road surface condition could be identified.. Such road sensors was tested on No. G50 highway in Chongqing, China from May. 2013. Experiment results show that the system could meet the requirements well.

9609-20, Session 4

Series-coupled fiber double-ring in Mach-Zehnder interferometer for temperature sensing

Yundong Zhang, Yongfeng Wu, Xuenan Zhang, Hui Li, Ping Yuan, Harbin Institute of Technology (China)

In this paper, we theoretically investigate the properties of the series-coupled fiber double-ring resonator in a Mach–Zehnder interferometer as highly sensitive temperature sensor. We acquire transfer function of this system by transfer matrix theory, and numerically analyze transmission of this system. This structure can achieve sharp asymmetric line shapes by controlling phase difference between the reference arm and sensing arm of Mach–Zehnder interferometer. Sharp asymmetric line shapes result from the interference between the electromagnetically induced transparency beam propagating in the sensing arm and continuous beam propagating in the reference arm. By comparison of phase difference between two arms of Mach–Zehnder interferometer, we acquired suitable phase difference of 0.5ϖ between the reference arm and sensing arm for sharpest asymmetric line shape around the resonance wavelength. At the same time, sharpest asymmetric line shape can achieve maximum sensitivity for sensing. We also analyze the effect of parameters of this sensing system on the sensitivity and the detection limit by measuring the intensity change at a fixed wavelength. For the 30dB signal/noise system, the temperature sensitivity and the temperature detection limit can achieve 21.689/°C and 0.461?10?4°C, respectively. Furthermore, we discuss the relationship between the temperature sensitivity and the temperature detection range, which obtain the inverse relationship between the temperature sensitivity and the temperature detection range. These results indicate that this structure is suitable for highly sensitive, compact and stable sensors.

9609-21, Session 4

Integrated multi-color illumination source for lab-on-a-chip fluorescence analysis

Abdullah J. Zakariya, CREOL, The College of Optics and Photonics, Univ. of Central Florida (United States); Ishaq Mulla, Ministry of Electricity & Water (Kuwait)

We propose an integrated microfluidic optical system device design for a monolithic integration of blood plasma analysis in a single step using microfluidic channels on a tri wavelength LED source emitting wavelengths in ultraviolet, infrared and visible. The device is a miniature disposable Lab-on-a-Chipas small as 6x 1.5mm with a blood plasma reservoir volume of 2?l providing instantaneous results. The device is fabricated using minimal lithographic fabrication steps and consists of a microfluidic Polydimethylsiloxane (PDMS) layer on top of a quantum well (QW) structure. The PDMS layer has three 100?m thick microfluidic channels connected to the 2?l reservoir where the blood plasma is injected. The three microfluidic channels pass over the QW substrate which is micro fabricated

to produce three LEDs that emit light in three different wavelengths on a single structure. The LEDs emit light in UV, infrared and visible and can be controlled individually for specific plasma testing or can emit light simultaneously depending on the application. To operate the device, first current is injected into the LEDs to turn on light emission. Light travels within the LED structure and at the same time light is emitted through the surface. Light can be either collected from the top of the device or the output facets by focusing the channels output on a spectrometer to collect the spectra of the device and analyze the output. The device is compact in size and provides fast, low power consumption and cost effective point of care devices with minimal heat output.

9609-22, Session 4

Mechanically induced long period fiber gratings on single mode tapered optical fiber for structure sensing applications

María G. Pulido-Navarro, Sigifredo Marrujo-García, José A. Álvarez-Chávez, Jesús S. Velázquez-González, Fernando Martínez-Piñón, Ctr. de Investigación e Innovación Tecnológica (Mexico); Ponciano J. Escamilla-Ambrosio, Ctr. de Investigación en Computación (Mexico)

The modal characteristics of tapered single mode optical fibers and its tension sensing characteristics by using mechanically induced long period fiber gratings are presented in this work. Both LPG and fiber tapers are fiber devices that couple light from the core fiber into the fiber cladding modes. The mechanical LPG is made up of two plates, one flat and the other grooved. For this experiment the grooved plate was done on an acrylic slab with the help of a computer numerical control machine. The manufacturing of the tapered fiber is accomplished by applying heat using a butane flame burner and stretching it, where the protective coating has been removed. Then, a polymer-tube-package is added in order to make the sensor sufficiently stiff for the tests. The induced MLPG is accomplished by putting the tapered fiber in between the two plates, so the taper acquires the form of the grooved plate slots. Using a white light the transmission spectrum showed a large peak transmission attenuation of around -40 dB. The resultant attenuation peak wavelength in the transmission spectrum shifts with changes in tension showing a strain sensitivity of 2pm/μ?. This reveals an improvement on the sensitivity for structure monitoring applications compared with the use of a standard optical fiber. In addition to the experimental work, the supporting theory and numerical simulation analysis are also included.

9609-23, Session 4

PET and PVC separation system based on optical sensors

Grethell Georgina Pérez-Sánchez, Univ. Autónoma Metropolitana (Mexico); José A. Álvarez-Chávez, Ctr. de Investigación e Innovación Tecnológica (Mexico); José R. Pérez-Torres, Tecnológico de Estudios Superiores de Coacalco (Mexico); Armando Gómez-Vieyra, Univ. Autónoma Metropolitana (Mexico)

In this work experimental results of a separate PET and PVC bottles machine using optical sensors are shown.

Two aligned pump lasers diodes working at 810 nm wavelength emission and 1 Watt output power where used.

At the end of each laser a lens is allocated for generating a perpendicular line with respect to the laser emission, with this we cover a 50 cm length over a band where the plastic bottles are transported.

In the receptor, four photodetectors were used for the opto-electronic conversion, the output signal is filtered for noise reduction and amplified for later pass through an analog to digital converter.

When a PET bottle is transported, the signal is transmitted and detected, and when a PVC bottle pass, the photodetector doesn't receive a signal, then an alarm is activated in the control stage where the signal is processed for activating the electrovalves which send the PVC bottles to a second container.

The sensor design and the experimental results of the system are shown in the full article.

9609-33, Session 4

Design and development of wafer-level short wave infrared micro-camera

Ashok K. Sood, John W. Zeller, Yash R. Puri, Magnolia Optical Technologies, Inc. (United States); Harry Efsthadiatis, Pradeep Haldar, Univ. at Albany (United States); Nibir K. Dhar, U.S. Army Night Vision & Electronic Sensors Directorate (United States); Jay S. Lewis, DARPA/MTO (United States)

Low cost IR Sensors are needed for a variety of Defense and Commercial Applications as low cost imagers for various Army and Marine missions. SiGe based IR Focal Planes offers a low cost alternative for developing wafer-level shortwave infrared micro-camera that will not require any cooling and can operate in the Visible-NIR band. The attractive features of SiGe based IRFPA's will take advantage of Silicon based technology, that promises small feature size and compatibility with the low power silicon CMOS circuits for signal processing.

SiGe technology offers a low cost alternative for developing Visible-NIR sensors that will not require any cooling and can operate from 0.4- 1.7 microns. The attractive features of SiGe based IRFPA's will take advantage of Silicon based technology that can be processed on 12-inch silicon substrates, that can promise small feature size and compatibility with the Silicon CMOS circuit for signal processing.

In this paper, we will discuss the design and development of Wafer-Level Short Wave Infrared (SWIR) Micro-Camera. We will discuss manufacturing approaches and sensor configurations for short wave infrared (SWIR) focal plane arrays (FPAs) that significantly reduce the cost of SWIR FPA packaging, optics and integration into micro-systems.

9609-36, Session 4

Mid-infrared GeTe4 waveguide on silicon with ZnSe isolation layer

Vinita Mittal, James S. Wilkinson, Ganapathy S. Murugan, Univ. of Southampton (United Kingdom)

Integrated photonic devices for mid-infrared biosensing need highly sensitive planar optical waveguides for efficient and reproducible interaction of analytes with photons. GeTe4/ZnSe waveguides were designed and fabricated on silicon substrates for 2-14 μm band of the mid-infrared spectrum. Silicon is a convenient and cheap substrate to deposit and fabricate optical waveguides. GeTe4 has a refractive index of 3.3 and it needs a lower refractive index isolation layer between the silicon substrate and the GeTe4 core to realise low loss optical waveguides. Numerical modelling was carried out to calculate the thickness of the isolation layer (ZnSe, refractive index ~2.4) required on high refractive index silicon substrate to achieve low loss waveguides. For a monomode slab waveguide of GeTe4 with a loss between 0.1 and 0.01dB/cm due to the underlying silicon, it was found that ~ 3 μm thick ZnSe film is required at 6.5 μm wavelength. ZnSe films about 3 μm thickness were deposited on silicon and were characterised for its structure and morphology by XRD and SEM, and surface roughness was measured by AFM. Photolithography was used to fabricate channel patterns on ZnSe films using a lift-off resist and GeTe4 was deposited on the patterned sample and finally photoresist removed to form channel waveguides of various widths. Optical characterization of these waveguides is underway and the results will be presented at the conference.

9609-24, Session 5

Long-term infrared background compensation for faint objects and variable backgrounds: a feasibility study

Paul D. LeVan, Air Force Research Lab. (United States); Mark Stegall, Greg Pierce, SE-IR Corp. (United States)

One class of Focal Plane Array (FPA) drive and data acquisition electronics (the "SE-IR System", working with the CamIRaTM software package), has successfully operated 100s of FPA types over the years. Many of these have been configured with different types of optical systems that gather spectral images, collect high spatial resolution bandpass images, or perform other novel functions.

An emerging capability exists for an infrared camera mounted on a commercial tracking platform. These platforms, popular with amateur astronomers, now offer high levels of pointing control and include a "guider port" that accepts pulse width modulation (PWM) error signals generated by centroiding of a bright source. A variation on the use of the guider port to "dither" the tracking platform in synchronization with the continuous collection of infrared images would effectuate highly efficient background subtraction, even when spatial gradients and temporal drifts are present in the background.

We describe an embodiment of the SE-IR system that provides the dither signal to the tracking platform and tags the imagery with the polarity of the dither, to distinguish between source & background, and background-only images. Such a capability would result in high performance background subtraction over long (hours) timeframes, realizing increases in SNR for very faint (in some cases, fractional A-to-D LSB) sources.

9609-25, Session 5

High-performance near-infrared spectrally encoded microscopy by using a balanced detector

Jluling Liao, Wanrong Gao, Nanjing Univ. of Science and Technology (China)

Spectrally encoded microscopy (SEM) is a new microscopic imaging technique in which a grating is used to illuminate different positions along a line on the sample by distinct wavelengths. The size of system and the imaging time can be dramatically reduced which replaced rapid scanning by spatial spectral encoding. In this paper, a SEM device is described which is based on a swept source and a balanced detection. A near-infrared wavelength is used in our system?which central wavelength is 1302.5 nm, and the available bandwidth is over 94 nm. A fixed gain balanced detector (BD) was employed in imaging test to detect the low sample light without amplifier. Compared to conventional SEM detection method, our BD-SEM device has two significant advantages, one is its capability of suppressing common-mode noise and thermal noise, resulting in the lateral resolution is better than directly detection, the other is that it can amplify the signal intensity which is particularly helpful for tissue reflectance imaging. With the purpose of testing the actual performance of BD-SEM, the lateral resolution was measured by imaging a USAF resolution target. The images of onion cells showed that the signal noise ratio was increased. The data showed that both the lateral resolution and signal noise ratio are better than non-BD method. The method presented in this work is helpful for developing miniature endoscopic probe for in vivo tissue visualization with high acquisition speed and high imaging quality.

9609-31, Session 5

Metal bonding to enable contact to three-dimensional antenna-coupled intersubband detectors

Robert L. Brown, Alan Selewa, Sung Jun Jang, Alireza Bonakdar, Mohsen Rezaei, Hooman Mohseni, Northwestern Univ. (United States)

III-V semiconductor-based mid- and long-wave infrared detectors are desirable due to their relatively low-cost and mature fabrication technology compared to the state-of-the art. However, these detectors are fundamentally limited by their weak absorption due to their intersubband mechanism and can never approach the performance of Mercury-Cadmium-Telluride detectors in a traditional arrangement. However, these limits can be overcome when coupling a small-volume of intersubband detector with an antenna. The small volume will greatly reduce dark current and thus noise. The antenna-coupling can effectively increase the optical area relative to the electrical area as well as boosting (or at least compensating for) quantum efficiency. Due to the prevalence of non-radiative processes in the recombination rate, the increase in local-density of states (LDOS) is negligible for this configuration.

However, the integration of a significantly small absorber with an efficiently-coupled antenna is not trivial and requires novel 3D processes. Previous attempts at this have had multiple problems including: large distance between antenna and absorber, inefficient antenna, complex wafer-transfer process, dead-space, and incompatibility with an FPA arrangement. We recently proposed an embedded antenna structure that would overcome these issues, but had difficulty making contact to these 3D structures. We propose the use of metal-to-metal bonding to directly integrate metal contacts or potentially antenna structures with infrared detectors. This offers two advantages over a once-chip solution: 1) Multiple processing steps can be done on the second substrate, eliminating some complexity. 2) Device contacts and antennas can be on a rigid surface instead of "floating" as previously proposed.

9609-34, Session 5

Development of high gain avalanche photodiodes for UV imaging applications

Ashok K. Sood, John W. Zeller, Roger E. Welser, Yash R. Puri, Magnolia Optical Technologies, Inc. (United States); Mi-He Jee, Russell D. Dupuis, Georgia Institute of Technology (United States); Nibir K. Dhar, U.S. Army Night Vision & Electronic Sensors Directorate (United States); Jay S. Lewis, DARPA/MTO (United States)

High resolution imaging in UV band has a lot of applications in Defense and commercial applications. The shortest wavelength is desired for spatial resolution which allows for small pixels and large formats. UVAPD's have been demonstrated as discrete devices demonstrating gain. The next frontier is to develop UV APD arrays with high gain to demonstrate high resolution imaging.

We will discuss model that can predict sensor performance in the UV band using APD's with various gain and other parameters for a desired UV band of interest. SNR's can be modeled from illuminated targets at various distances with high resolution under standard atmospheres in the UV band and the solar blind region using detector arrays with unity gain and with high gain APD's.

We will present recent data on the GaN based APD's for their gain, detector response, dark current noise and the 1/f noise. We will discuss various approaches and device designs that are being evaluated for developing APD's in wide band gap semiconductors. The paper will also discuss state of the art in UV APD and the future directions for small unit cell size and gain in the APD's.

9609-35, Session 5

Large format MBE HgCdTe on silicon detector development for astronomy

Brandon J. Hanold, Donald F. Figer, Joong Y. Lee, Kimberly E. Kolb, Iain Marcuson, Rochester Institute of Technology (United States); Elizabeth Corrales, Jonathan Getty, Lynn Mears, Raytheon Co. (United States)

The Center for Detectors at Rochester Institute of Technology and Raytheon Vision Systems (RVS) are leveraging RVS capabilities to produce large format, short-wave infrared HgCdTe focal plane arrays on silicon (Si) substrate wafers. MBE grown HgCdTe on Si can reduce detector fabrication costs dramatically, while keeping performance competitive with HgCdTe grown on CdZnTe. Reduction in detector costs will decrease a dominant expense for telescopes. This paper presents the characterization of 2.5μm cutoff MBE HgCdTe/Si detectors including pre- and post-thinning performance. Detector characteristics presented include dark current, read noise, spectral response, persistence, linearity, crosstalk probability, and analysis of material defects.

9610-1, Session 1

Site suitability evaluation for ecotourism potential areas using remote sensing (RS) and geographic information system (GIS): a case study of Wadi Wurayah, Fujairah, United Arab Emirates *(Invited Paper)*

Ali Abou-Elnour, Ajman Univ. of Science & Technology (United Arab Emirates); Ahmad Abouelnour, Varkki Pallathucheril, American University of Sharjah (United Arab Emirates)

UAE views sustainable development as the best way to provide stability and security for all peoples of the world. One of the main approaches to achieve sustainable development was adopted by the UAE by preserving environmental sustainability and integrating environmental preservation into national planning for a diversified economy. Tourism is one of the major sector that UAE depends on to diversify and grow the economy sustainably. Based on the World Travel and Tourism Council (WTTC) in 2012 the estimated total value added generated by the UAE travel and tourism sector approximately accounting for a 14.3% share of GDP. The UAE travel and tourism sector value-added percentage share is expected to register an average annual growth rate of 5% and to reach about 16.4% of the total by 2023. As UAE features some of the most stunning landscapes and beautiful natural attractions in the region, it has been named among the top 10 fastest growing tourism hotspots in 2013, according to the United Nations World Tourism Organization (UNWTO) report. However, UAE is always dedicated to develop low-impact, eco-friendly tourism across the country, so visitors can take in the natural majesty that stretches across the country while leaving the landscape pristine and untouched.

Ecotourism helps drive conservation efforts, protecting wildlife for generations to come. The UAE includes more than 5036.24 km2 of protected area which represents 6.044 % of its total area. These protected areas are distributed in Abu Dhabi, Dubai, Sharjah, Ajman, and Fujairah. In 2006, the Government of Fujairah, Emirates Wildlife Society (EWS), and World Wide Fund (WWF) for Nature joined forces to begin conservation efforts for Wadi Wurayah in Fujairah. After three years of assessment and research, on March 16, 2009, Wadi Wurayah officially became the UAE's first protected mountain area in the United Arab Emirates in order to protect fresh water springs, pools and streams that provide its unique wildlife with a renewable and safe drinking resource. In 2010, Ramsar Convention, which is an intergovernmental treaty which commits member countries to maintaining the ecological character of their Wetlands, listed Wadi Wurayah as a Wetland of International Importance for its important freshwater catchments, which provide sustenance for a number of native species as well as migratory birds. In January 2013, the Fujairah government appointed EWS-WWF to lead the development of a management plan of Wadi Wurayah National Park and ensure environmental protection according to best international standards. In 2014, after declaring the Wadi as the UAE's first National Park, the area was also closed to the public to allow the ecosystems to revive without any interference. The current developments in Wadi Wurayah are set to take things forward to ensure active protection of the rich biodiversity and the natural and cultural resources of the area and, to deliver a unique model of how environment conservation can be economically viable.

In the last decade, Geographic Information Systems (GIS) is efficiently used in tourism as a decision supporting tool for sustainable tourism planning and tourism site selection. The aim of the present work is to identify and prioritize the potential ecotourism sites in Wadi Wurayah, Fujairah, UAE using GIS. The present work assesses the potential suitable areas for ecotourism based on bio-physical characteristics of the land ecosystems and socio-economic data. The characteristics are landscape or naturalness like visibility and land use or cover, the topography like elevation and slope, the accessibility like distance from roads, and community characteristics like settlement size. These criteria and factors were selected according to the professional expert's opinions.

After developing the list of ecotourism criteria, GIS techniques were used to measure the ranking of different sites according to the set criteria and thus identify those with the best potential. Subsequently, the land suitability map for ecotourism was created. The degree of suitability of each factor was classified as highly suitable, moderately suitable, marginally suitable, and not suitable for ecotourism. Based from the suitability map, the areas of highly ecotourism potential are located in protected areas. These areas can be used for education as well as conservation. It could serve as main ecotourism attractions but with the use of certain limitations and guidelines. The areas of moderately ecotourism potential can be developed as ecotourism destination by facilitating proper ecotourism infrastructure and services and can still be considered for ecotourism attractions. The marginally suitable areas are suitable for tourism development in general. However, the not suitable areas for ecotourism have several effects of development and degraded environment. As concerns theirs utilization, they may have some environmental problems but these are controllable. The methodology proposed was useful in identifying ecotourism sites by linking the criteria deemed important with the actual resources of the province. This study result helped to identify optimal use of the land for tourism facilities development and ecotourism resource utilization within Wadi Wurayah province in near future. GIS Additionally, it may also serve as a starting point for more complex studies in the future.

9610-2, Session 1

Evaluations of cropland representations in CMIP5 simulations *(Invited Paper)*

Min Xu, Forrest Hoffman, Oak Ridge National Lab. (United States)

Cropland is possibly the sector among earth system most affected by climate change and is the major source of carbon lost to the atmosphere and contribute directly to emissions of greenhouse gases. There is, however, large potential for cropland to reduce its carbon flux to the atmosphere and sequester soil carbon through soil and crop managements including no-tillage, perennial and/or deep root crops, irrigation, and organic fertilization etc. But these estimations over cropland remain largest uncertain among all other terrestrial biomes. In most models in CMIP5, the cropland is generally treated similarly as grassland without accounting for realistic crop phenology and physiology processes, and the managements. In this study, we will evaluate how well cropland is represented in CMIP5 simulations and how to improve the representations and reduce the uncertainties over cropland. We will compare the modeled biogeochemical variables against multiple observational data including various remote sensing products and in-situ data.

9610-3, Session 1

UV irradiance products from combined TOMS-OMI satellite and UVMRP ground measurements across the continental U.S. *(Invited Paper)*

Zhibin Sun, John Davis, Wei Gao, Colorado State Univ. (United States)

Increasing surface ultraviolet (UV) irradiance has been a global concern as it is harmful to humans and agriculture. There are agencies monitoring the UV irradiance by providing observational products to the public. All such products have different temporal and spatial resolutions. So far only some comparisons among them have been conducted. This study combines optimally two kinds of surface UV irradiance observations, TOMS-OMI and UVMRP (Ultraviolet-B Monitoring and Research Program), based on data

fusion methodology. The final product takes advantage of both sources, wide coverage from TOMS-OMI and more accurate ground measurement from UVMRP. Besides the four wavelengths from TOMS-OMI, the product can provide the daily surface UV irradiance across the continental U.S. for any wavelengths between 305nm and 380nm, which can be accessed for public or scientific usage.

9610-4, Session 1

Mapping the lawn in urban area using airborne LIDAR and aerial visible images

Hongbo Su, Florida Atlantic Univ. (United States); Ni-Bin Chang, Univ. of Central Florida (United States)

According to a recent study, 36 states in US anticipate local, regional or statewide water shortage. Homeowners in USA usually use 30%-70% of their water outdoor if the house doesn't use a Xeriscape landscaping design. One example is golf course which is not considered an environmental friendly land use. To get an accounting of water consumed by the lawn irrigation and to understand the ecological consequences of the lawn care, it is necessary to measure the lawn size and map their locations accurately for urban areas where we see more active anthropogenic activities. In this study, remote sensing technology and image fusion techniques are used to achieve that goal, based on the high resolution airborne Lidar images and aerial images in visible bands.

Experiments shows that using then aerial images alone is not sufficient to accurately map the lawns due to the contamination of shadow and cloud, although its spatial resolution is as high as 0.5 feet per pixel. To improve the mapping of lawn, the airborne Lidar images with an elevation accuracy of 15cm and a spatial resolution of 1.5 meter are employed in combination with the aerial visible images. A new image fusion technique based on hue-saturation-intensity (HSI) transforms is developed to merge the Lidar and visible images to retrieve the lawn information. In this study, Palm Beach County in south Florida is chosen as the study area, since it is a place with a high density of golf courses which raises a concern on their environmental impact.

9610-5, Session 1

Continuous evaluation of land cover restoration of tsunami struck plains in Japan by using several kinds of optical satellite image in time series

Hideki Hashiba, Nihon Univ. (Japan)

The Mw 9.0 earthquake that struck Japan in 2011 was followed by a large-scale tsunami disaster in the Tohoku region. The damage situation of coastal plane was extensively reported by many satellite images, and ongoing evaluation of the restoration process is requested to many kind of satellites. Especially, an effective long-term monitoring is demanded for reconstructing the urban land cover and the recovering farmland, grassland and coastal forest that collapsed under the large tsunami. Moreover, modeling of changing trend of the land cover dynamics in plains after disaster using time series satellite data can be effectively used for measures at large-scale tsunami disaster of the future. However, remote satellite capture of long-term restoration processes is compromised by accumulating spatial resolution effects and seasonal influences. It is necessary to devise the data selection and the construction of data set for these reasons. In this study, the restoration process three years following the disaster in a part of Sendai plain located in northeast region in Japan was deduced from same season satellite images acquired by different optical sensors. The coastal plains struck by the tsunami were evaluated by land cover classification processing using clustering method. The changes in land cover were analyzed from time series optical images acquired by the Landsat 5/TM, 7/ETM+, 8/OLI, EO-1/ALI, and ALOS/AVNIR2 satellites. The study revealed several characteristics of the change in the inundation area and signs of artificial and natural restoration.

9610-6, Session 1

In situ hyperspectral data analysis for chlorophyll content estimation of an invasive species spartina alterniflora based on PROSAIL canopy radiative transfer model

Jinquan Ai, East China Normal Univ. (China); Wei Gao, Colorado State Univ. (United States); Runhe Shi, East China Normal Univ. (China); Zhibin Sun, Colorado State Univ. (United States); Wenhui Chen, Fujian Normal Univ. (China); Chao Zhang, Pudong Liu, Yuyan Zeng, East China Normal Univ. (China)

An accurate quantitative estimation of invasive species chlorophyll content is of great importance for monitoring ecosystem health and estimating biomass or carbon stock change by alien invasion species. This paper aims to analyze the capabilities and limitations for retrieving chlorophyll content of wetland vegetation at the canopy level. The hyperspectral reflectance of an invasive species Spartina alterniflora was measured using a Spectroradiometer with spectral range of 350-2500 nm in late autumn in a sub–tropical estuarine marsh. We used the PROSAIL canopy radiative transfer model to estimate chlorophyll content. Frist, sensitivity analysis was done to determine input parameters change and simulate canopy reflectance. Then, the best vegetation index for estimating chlorophyll content was selected from a series of hyperspectral vegetation indices. The results showed that the PROSAIL model was able to predict canopy leaf chlorophyll content of S. alterniflora with reasonable accuracy later in the growing season.

9610-7, Session 1

Monitoring forest biodiversity using imaging spectroscopy based on leaf biochemical variations in subtropical forest

YuJin Zhao, Yuan Zeng, Bingfang Wu, Qianjun Zhao, Dan Zhao, Institute of Remote Sensing and Digital Earth (China)

Forest biodiversity is a key element in the provision of ecosystem service, function and stability. Monitoring forest biodiversity is essential to the conservation and management of forest resource.In the past two decades, imaging spectrometry technique has been widely applied in forest biodiversity mapping or tree species identification. A new method called "spectranomics" that maps forest species richness based on leaf chemical and spectroscopic traits using imaging spectroscopy, has been developed. In this paper, this method would be used for detecting the relationship among the spectral, biochemical and taxonomic diversity of tree species based on 20 dominant canopy species collected in the Shennongjia National Forest Nature Reserve.Firstly, sixteen leaf biochemical components including pigments, water, Specific Leaf Area (SLA), nitrogen, phosphorus,cellulose,lignin and trace elements are standardized to indicate the unique combinations for each species. The hierarchical cluster analysis based on spectral reflectance signatures in 400-2400nm are applied to divide forest species to different clusters. Furthermore, the Constrained Partial Least Squares(PLS-PRESS) regress analysisisused to establish the relationship between biochemical and spectral signatures. Finally, a Monte-Carlo simulation model is used to find the species richness changes caused by the biochemical and spectral properties. The results show that the biochemical components could be well quantified by spectral signatures ($R2>0.43$, $P<0.01$; excluding the trace elements) for identifying the subtropical forest species richness.

9610-8, Session 1

Detecting response of rice phenology to cold and heat damages using time series analysis of MODIS images

Shenbin Yang, Shuanghe Shen, Nanjing Univ. of Information Science & Technology (China); Chunlin Shi, Jiangsu Academy of Agricultural Sciences (China)

This paper focuses on the evaluation of the capability of MODIS-EVI time series to detect the response of rice phenology to cold and heat damages during single rice season in the middle and lower reaches of Yangtze River Plain. Field experiment data and MODIS-EVI time series of 2012 and 2013 were used. At first, the slops of MODIS-EVI time series at increasing phase were analyzed with accumulated hot temperatures, and slops at decreasing phase were analyzed with accumulated cold temperatures. Then, empirical relationships were constructed by taking the accumulated cold and hot temperatures as a function of slops, respectively. Obtained empirical relationships were also classified according to the seriousness of cold and heat damages to rice phenology. Finally, based on the classification and application of the empirical relationships to all rice pixels in the study area in 2012 and 2013 respectively, the regional response of rice phenology to heat damages before flowering and cold damages after flowering were obtained. The result showed that heat damages shorten the phenology and lead to higher slops, while cold damages extend the phenology and lead to lesser slops. The estimated regional patterns of the adverse temperature damages were well consistent with the real situation, with different color representing different level of influences. Large discrepancies could be for the reason of different rice paddy management and difference in rice species. In addition, mixed rice pixels may have unpredictable results, since the changes of the slops are somehow determined by other land types instead of rice paddy. In conclusion, MODIS-EVI time series are able to detect the influence of cold and heat damages to rice phenology, but more validations have to be performed.

9610-10, Session 2

Seasonal urban heat island effect in Tampa Bay under the varying hydrological patterns *(Invited Paper)*

Ni-Bin Chang, Univ. of Central Florida (United States); Kaixu Bai, Univ. of Central Florida (United States) and East China Normal Univ. (China); Wei Gao, Colorado State Univ. (China)

Urban heat island effect exhibits some fundamental features of complex self-organizing systems with seasonality effect regulated by some hydrological patterns. For instance, as soil moisture is affected by both water and energy balances in the soil-vegetation-atmosphere system, it involves many complex processes in the nexus of water and thermal cycles at the surface of the urban environment. Yet soil moisture is modulated by precipitation, stormwater runoff, vegetation cover, and evapotranspiration (ET) in urban regions associated with different land use and land cover. But how these hydrological patterns affect the land surface thermal fluxes have not yet been fully explored. The advent of urban hydrology and remote sensing technologies opens new and innovative means to undertake event-based assessment of hydrological effects in urban regions. In this study, remote sensing images related to land use and land cover, soil moisture, precipitation, ET, the Enhanced Vegetation Index (EVI), and Land Surface Temperature (LST) have been pieced together to investigate the profound impact of seasonal urban heat island effect and identify the hot spots and hot moments over time. Maximum Covariance Analysis was used to explore the spatiotemporal interactions among those relevant hydrological and geographical factors relative to LST. These designated patterns above were performed for Tampa Bay area on the 2 km x 2km grid in Florida. Finally the Extreme Learning Machine was applied to simulate the complex relationships between those associated factors and LST in urban regions as well as quantify the relative contribution of each factor to seasonal variations of LST.

9610-11, Session 2

Incorporation of crop growth models into climate weather research and forecasting model: biophysical feedbacks of maize growth to regional climate *(Invited Paper)*

Xin-Zhong Liang, Min Xu, Xuesong Zhang, Univ. of Maryland, College Park (United States); Wei Gao, Colorado State Univ. (United States)

A regional Climate-CROP coupled modeling system was established by implementing crop growth models with comprehensive phenology and physiology processes to the Climate Weather Research and Forecasting (CWRF) model (hereafter denotes CWRF-CROP) The crop growth models from the Crop Environmental Resource Synthesis (CERES) maize and wheat, and the GOSSYM cotton, and the Decision Support System for Agrotechnology Transfer (DSSAT) soybean growth models were reengineered following FORTRAN90 module and data structures and then incorporated into the CWRF-CROP coupled system. In this study, we will preliminary evaluate the biophysical feedbacks of maize growth in U.S. Midwest Corn Belt to present and future regional climates and future climate changes using CWRF-CROP driven by the CCSM4 global simulations under historical and future RCP8.5 emission scenarios. The key biophysical parameters including leaf and stem area index (LAI and SAI), canopy height and width, and root length density are dynamically simulated by the CERES-maize module of CWRF-CROP and are returned to the CWRF land surface component to calculate the land-atmosphere fluxes and feedbacks of crop growth to regional climate. Preliminary results indicate that the feedbacks of maize growth to regional climate are substantial, especially for surface climate, including surface air temperature, humidity, and precipitation. In future, further study will be conducted on the impacts of crop growth on regional hydrology and the mitigations of crop managements in responses to anticipated climate changes.

9610-12, Session 2

Land cover fraction estimation with global endmembers using collaborative SUnSAL

Uttam Kumar, Cristina Milesi, NASA Ames Research Ctr. (United States); S. Kumar Raja, EADS Innovation Works, Airbus Engineering Ctr. (India); Ramakrishna Nemani, NASA Ames Research Ctr. (United States); Sangram Ganguly, NASA Ames Research Ctr. (United States) and Bay Area Environmental Research Institute (BAERI) (United States); Weile Wang, California State Univ. (United States) and NASA Ames Research Ctr. (United States)

Land cover (LC) refers to the physical state of the Earth's surface such as soil, vegetation and water, etc. However, most LC features occur at spatial scales much finer than the resolution of the primary remote sensing satellites. In this paper, we explore the possibility of Collaborative Sparse Unmixing for estimation and quantification of LC classes at subpixel level to obtain abundance maps in both the unconstrained and constrained forms (with abundance nonnegativity and abundance sum-to-one constraints imposed).

Firstly, computer simulated noise-free and noisy data (Gaussian noise of different noise variance: 2, 4, 8, 16, 32, 64, 128 and 256) were unmixed with a set of global endmembers (substrate, vegetation and dark objects) in the NASA Earth Exchange. In the second set of experiments, a spectrally diverse collection of 11 cloud free scenes of Landsat-5 TM data representing an agricultural set-up in Fresno, California were unmixed and validated using ground vegetation cover. Finally, Landsat TM data for an area of San Francisco (an urbanized landscape) were used to assess the algorithm and compared with the fractional estimates of World View 2 data (2 m spatial resolution) for validation. The results were evaluated by using descriptive statistics, correlation coefficient, RMSE, probability of success, boxplot and bivariate distribution function. With computer simulated data,

both unconstrained and constrained solutions gave excellent results. For an agricultural setup mean absolute error (MAE) of vegetation fraction between actual and estimated values was 0.08 for both unconstrained and constrained case and for the urban landscape, the MAE was 0.72 (unconstrained) and 0.07 for the constrained solution.

9610-13, Session 2

Effects of errors in solar radiation inputs on ecosystem model performance

Shinichi Asao, Zhibin Sun, Wei Gao, Colorado State Univ. (United States)

Solar radiation inputs drive many processes in terrestrial ecosystem models. The processes (e.g. photosynthesis) account for most of the fluxes of carbon and water cycling in the models. It is thus clear that errors in solar radiation inputs cause key model outputs to deviate from observations, parameters to become suboptimal, and model predictions to loose confidence. However, errors in solar radiation inputs are unavoidable for most model predictions since models are often run with observations with spatial or / and temporal gaps. As modeled processes are non-linear and interacting with each other, it is unclear how much confidence most model predictions merits without examining the effects of those errors on the model performance. In this study, we examined the effects, using a terrestrial ecosystem model, DayCent, parameterized for a shortgrass prairie of US. Using observed solar radiation values, we introduced both bias and random noise to simulate the errors in solar radiation inputs. Resulting deviations in model outputs were analyzed for their relationship with the bias and the noise. The results show that biases less than 20% produced much smaller deviation in model outputs, but the deviations varied inter-annually, depending on different parameterization and environmental factors. Even a small deviation in daily fluxes accumulated to large deviation in pool sizes in long-term simulations. We conclude that small errors in solar radiation inputs reduce confidence by only a little for short-term predictions, but greatly for long-term predictions and for parameterization and application elsewhere.

9610-14, Session 2

Visualization of remote sensing image positioning uncertainty

Jiao Weili, Saiguang Ling, Yiqing Yu, Tengfei Long, Guojin He, Institute of Remote Sensing and Digital Earth (China)

It is inevitable to bring about uncertainty during the process of data acquisition. The traditional method to evaluate the geometric positioning accuracy is usually by the statistical method and represented by the root mean square errors (RMSEs) of control points. It is individual and discontinuous, so it is difficult to describe the error spatial distribution. Visualizing uncertainty is a representation method of the data quality. The purpose is to help users probe the uncertainty of original data for better understanding and using. In this paper the uncertainty range of each control point is deduced, and the uncertainty spatial distribution model between the control point and each arbitrary point is established. The distance between control points is introduced to evaluate the geometric accuracy of remote sensing image, and compared with the traditional method of RMSE. Then several visualization methods are studied to describe the geometric uncertainties of the remote sensing image, and kriging is used to visualize the geometric uncertainties as the spatial interpolation method. The uncertainties at any point in different directions are represented clearly by the contour lines and three-dimensional visualization map. The experiments show that the visualization methods can effectively and objectively represents the image geometric quality, and also can help users probe the reasons of bringing the image uncertainties.

9610-15, Session 2

Using artificial neural network and satellite data to predict rice yield in Bangladesh

Kawsar A. Akhand, The City Univ. of New York (United States); Mohammad Nizamuddin, Leonid Roytman, The City College of New York (United States); Felix Kogan, Mitch Goldberg, Ctr. for Satellite Applications and Research (United States)

Rice production in Bangladesh is a crucial part of the national economy and providing about 70 percent of an average citizen's total calorie intake. The demand for rice is constantly rising as the new populations are added in every year in Bangladesh. Due to the increase in population, the cultivation land decreases. In addition, Bangladesh is faced with production constraints such as drought, flooding, salinity, lack of irrigation facilities and lack of modern technology. To maintain self sufficiency in rice, Bangladesh will have to continue to expand rice production by increasing yield at a rate that is at least equal to the population growth until the demand of rice has stabilized. Accurate rice yield prediction is one of the most important challenges in managing supply and demand of rice as well as decision making processes. Artificial Neural Network (ANN) is used to construct a model to predict rice yield in Bangladesh. Advanced Very High Resolution Radiometer (AVHRR)-based remote sensing satellite data vegetation health (VH) indices (Vegetation Condition Index (VCI) and Temperature Condition Index (TCI)) are used as input variables and Rice yield is used as target variable for ANN prediction model. The result obtained with ANN method is encouraging and the error of prediction is less than 10%. Therefore, prediction can play an important role in planning and storing of sufficient rice to face in any future uncertainty.

9610-16, Session 2

Sensitivity analysis of canopy model parameters by EFAST method

Pudong Liu, Runhe Shi, Hong Wang, Wei Gao, East China Normal Univ. (China); Zhibin Sun, Colorado State Univ. (United States)

Abstract: Sensitivity analysis of plant canopy parameters basing on remote sensing model is a prerequisite for the inversion. As the limitation of local sensitivity analysis without considering the coupling effect among the parameters, the EFAST(Extended Fourier Amplitude Sensitivity Test) as a global sensitivity analysis method can be used not only the sensitivity of each parameter, but also the interacted influence among them. Based on PROSAIL model, the paper made a concentration to analyze the parameters' sensitivity by using EFAST method and simulated data so as to improve the inversion precision and develop the performance of model

9610-18, Session 2

A study on China's LUCC and carbon sink response with remote sensing

Zhiqiang Gao, Xiangyu Zheng, Jicai Ning, Yantai Institute of Coastal Zone Research (China); Wei Gao, Colorado State Univ. (United States)

Land use / land cover change (LUCC) is a core issue of global change research, which can not only influence regional and global climate change, but also is an important impact factor of carbon cycling. LUCC research is of great significance to expand national carbon emission space. Based on SPOT VEGETATION NDVI time-series data, multi-phase China's land use / land cover (LULC) data were extracted in this study, where land use degree method and land dynamic degree method were used to analyze the spatial and temporal change characteristics of China's land use / land cover data in the latest decade. Moreover, bookkeeping model was applied to analyze the response of China's carbon sink to vegetation cover change.

9610-19, Session 3

Long-term precipitation forecasting based on teleconnection signal propagation across North America *(Invited Paper)*

Ni-Bin Chang, Sanaz Imen, Univ. of Central Florida (United States); Kaixu Bai, Univ. of Central Florida (United States) and East China Normal Univ. (China)

Global sea surface temperature (SST) anomalies have a demonstrable effect on precipitation patterns throughout the continental U.S., which can be determined by statistical relationships between hydrological variables and the atmospheric-oceanic variables separated by large distances called 'hydroclimatic teleconnection'. However, the existence of non-stationary signals makes the identification of teleconnection complicated at a local scale. This means that it can hardly be analyzed by only relying on linear analysis across a wide region at sub-continental scale, and weak signals can be masked by anthropogenic effects. To address this need, this study aims to develop a method to assess the non-stationary teleconnection signals at a local scale using non-linear spectral wavelet analysis and remote sensing technology. To specify oceanic regions which have statistically significant contribution on precipitation pattern at a local scale, the pixel-wise linear correlation was applied to determine the correlation between the localized variation of wavelet power and dominant modes of the Atlantic and Pacific SST and precipitation variability. After removing noisy signals from the identified teleconnection signals, nonlinear models were simulated to forecast precipitation utilizing the reconstructed signals with the aid of extreme learning machine (ELM). The developed ELM forecasting methodology on a monthly scale was applied for three sites in the Northeast, the Northwest, and the Southwest United States. This method can improve the understanding and projections of the impacts of climate change at a local scale, and reveal the contribution of the Atlantic and Pacific SST on precipitation variability over three regions in the U.S.

9610-20, Session 3

Climate change impacts on the U.S. agricultural economy *(Invited Paper)*

Xin-Zhong Liang, You Wu, Robert G. Chambers, Univ. of Maryland (United States); Daniel L. Schmoldt, U.S. Dept. of Agriculture (United States); Chao Sun, Univ. of Maryland (United States)

Past records have shown that climate variations play a major role on U.S. crop yields. There has been, however, a lively debate about the potential impact of climate change on the overall economic growth of U.S. agriculture. A vital measure of an agricultural economy's growth is its rate of total factor productivity (TFP) that measures aggregate output produced per unit of aggregate input used. This study will present a comprehensive analysis using the U.S. national TFP records and observed high-resolution climate (precipitation and surface air temperature) geographic maps during 1950-2010. We will demonstrate that TFPC interannual variations strongly depend on climate conditions over distinct regions of intensive agricultural productions. We will then develop a statistical model to show that future U.S. agricultural productivity will be significantly altered by substantial climate changes projected over these regions.

9610-21, Session 3

Temporal variation (seasonal and interannual) of vegetation indices of corn and soybeans across multiple years in central Iowa

John H. Prueger, Jerry L. Hatfield, Agricultural Research Service (United States)

Remotely sensed reflectance parameters from corn and soybean surfaces can be correlated to crop production. Surface reflectance of a typical Upper Midwest corn /soybean region in central Iowa across multiple years reveal subtle dynamics in vegetative surface response to a continually varying climate. From 2006 through 2014 remotely sensed data have been acquired over production fields of corn and soybeans in central IA, U.S.A. with the fields alternating between corn and soybeans. The data have been acquired with ground-based radiometers with 16 wavebands covering the visible, near-infrared, and shortwave infrared wavebands and combined into a series of vegetative indices. These data are collected on clear days with the goal of collecting data at a minimum of once per week from prior to planting until after the fall tillage operations. Within each field, five sites were established and sampled during the year to reduce the spatial variation and allow for an assessment of the changes in the vegetative indices during the growing season. Ancillary data collected for each crop included the phenological stage at each sampling date with biomass collected at the onset of the reproductive stage and at physiological maturity. Evaluation of the vegetative indices for the different years revealed that patterns were related to weather effects on corn and soybean growth. Remote sensing provides a method to evaluate changes within and among growing seasons to assess crop growth and development as affected by differences in weather variability.

9610-22, Session 3

Two-stage reference channel calibration for collocated UV and VIS Multi-Filter Rotating Shadowband Radiometers

Maosi Chen, John Davis, Zhibin Sun, Wei Gao, Colorado State Univ. (United States)

Multi-Filter Rotating Shadowband Radiometer (MFRSR) and its UV version (UV-MFRSR) are ground-based instruments for measuring solar UV and VIS radiation. They are usually deployed together in field at USDA UV-B Monitoring and Research Program (UVMRP) sites. The Langley Analysis (LA) is applied on (UV-) MFRSR channels individually to generate calibration factors at all channels. It is observed that the performance of LA varies with channels and sites. We attribute it to the monotonically changing total optical depths (TOD) in the cloud screened points. Since (1) aerosol is main source of TOD variation at the 368nm channel and (2) UV-MFRSR measures direct normal and diffuse horizontal simultaneously, we use the Radiative Transfer Model (i.e. MODTRAN) to create the look-up table (LUT) of the ratio of direct normal and diffuse (DDR) with respect to aerosol optical depth (AOD) and solar zenith angle. The LUT is used to evaluate the quality of the Langley Offset (VLO) by giving lower weights to VLO generated from points with monotonic variation in AOD. With the 368nm channel and other calibrated channels as Reference Channels (RC), the most stable points in RC are selected and LA is applied to the adjacent un-calibrated channel (TC) on those points to generate VLO in TC. The test of this method on the UVMRP site at Homestead, Florida shows that (1) The long-term trend of the original LA VLO is impacted by the monotonic changing in AOD at 368nm channel; and (2) more clustered VLO at shorter wavelength are generated compared with the original LA method.

9610-23, Session 3

Water stress detection of lilac leaves using a polarized laser

Songxin Tan, A. S. M. K. Khan, South Dakota State Univ. (United States)

Vegetation stress detection is of great importance to many agricultural and ecological studies. Vegetation water stress is commonly encountered in many areas. The accurate detection of water stress may not only save the vegetation from dying, but also may enable more efficient use of limited water resource.

Plant leaf water content is one of the primary factors indicating vegetation health condition. In this study, a linearly polarized Nd:YAG laser at 532-

nm was used in the lab to study water stress from plant leaves. Leaf samples were collected and brought into the lab for measurement. An optical measurement system was built. Polarimetric measurements of the backscattered laser light were conducted as the leaf samples continued to lose water in the lab. The same measurement procedures were repeated several times until the leaf samples were almost completely dry. Preliminary study indicates that depolarization ratio is a good indicator of water stress in the studied case. In addition, an overall increasing trend of depolarization ratio under water stress condition was also observed.

9610-24, Session 3

Raman spectroscopy for the control of the atmosphere bioindicator

Elena V. Timchenko, Larisa A. Zherdeva Taskina, Nikolay V. Tregub, Pavel E. Timchenko, Ludmila A. Shamina, Samara State Aerospace Univ. (Russian Federation)

In view of ability to accumulate pollutants, plant facilities are effective markers of the ecological state of the atmosphere, which in contrast to traditional methods for measuring concentrations of pollutants express resistive functions of the biological environment to external influence, including the multiple factors and types of pollutants.

Experimental studies of the optical parameters of various bioindicators of the atmosphere (woody plants and soil types) using the method of Raman spectroscopy were presented. Changes in the optical parameters were studied for objects, under the direct influence of light, so for objects in the shadows, as well as age-appropriate bio-indicators.

The spectral characteristics of the samples were studied using experimental stand implementing the Raman method and includes a high-resolution digital spectrometer Shamrock sr-303i with a built-in cooling camera DV420A-OE, fiber-optic probe for Raman spectroscopy RPB785, combined with laser module LuxxMaster LML-785.0RB-04 (power of 150 mW, wavelength 785 nm).

The research resulted in produced the following conclusions:

- Tthe spectral characteristics of different types of biological indicators, depending on the level of illumination, experimentally established.

Shown that the ratio of the intensities of Raman wavenumbers at 730 cm-1 and 1600 cm-1 does not depend on the level of illumination for two bio-indicators - dandelion (Taraxacum) and silver birch (Betula pendula);

- Established that the statistical scatter parameters for optical bio-indicators wood ranged from 9% to 14%, and for the plant - from 4% to 8.7%.

- On the basis of the results obtained as a bio-indicator of atmospheric emissions was chosen dandelion (Taraxacum).

9610-25, Session 3

Study of emissivity changes presented by inorganic and organic soil under drying at ambient temperature

Carlos Villaseñor-Mora, Arturo Gonzalez-Vega, Haydee Hernández-Arellano, Univ. de Guanajuato (Mexico); Pablo Martinez-Torres, Univ. Michoacana de San Nicolás de Hidalgo (Mexico)

In this work, it is investigated the applicability and suitability of infrared thermography to study the degree of moisture of different kinds of soils. This technique could be applied to measure soil water content in a fast way, which could be helpful in both agricultural and environmental fields. In the first part of this study, the emissivity of the dry soils, with different and controlled content of organic matter, were characterized using an infrared camera and an integrating sphere, the emissivity was measured indirectly by reflection and absorption for the sample. To perform the experiments to measure the emissivity of the wet soils as a function of water loss, first the samples were wetted to field capacity, then, it was acquired a sequence of thermal images in time to follow the different stages of drying of the studied samples. The content of humidity was monitored by conventional method. These measurements were compared with the infrared thermography procedure developed, and it was observed that the wet soils show different thermal emissivity behaviors when they are losing humidity. This behavior is strongly influenced by the percentage of organic matter content in the soil studied. Also, if the organic matter is predominant in the soil, the emissivity varies inversely proportional to the moisture content in the soil, however, if the soil is completely inorganic, the behavior of the emissivity is directly proportional to the moisture content in the soil.

9610-26, Session 3

Accurate extracting of moso bamboo from Landsat TM based on a constrained linear least square method

Yixiang Wang, Zhejiang Agriculture & Forestry Univ. (China) and Colorado State Univ. (United States); Zhibin Sun, Colorado State Univ. (United States); Shangbin Bai, Zhejiang Agriculture & Forestry Univ. (China) and Colorado State Univ. (United States)

Accurate extracting of moso bamboo is important for accounting its carbon sink, evaluating its expansion and predicting its implication management. Landsat TM image have been widely used for moso bamboo extracting because it covers large areas more efficiently than the traditional inventory. Using different bands from satellite data, this study applied an optimization method, constrained linear least square, to extract all moso bamboo forest image grids in Tianmu Mountain National Natural Reserve in Southern China. Ground truthing of the bamboo forest was performed by randomly locating 100 grids. Field surveys using GPS confirmed all of the grids were moso bamboo forest in this region and the bamboo distribution map was drawn for further research. This algorithm can also be applied to extract other forest types in satellite images.

9610-28, Session PWed

Rapid urban sprawl stimulated by increasing GDP and rising urban land price in east China coast from 2000 to 2009

Qingshui Lu, Yantai Institute of Coastal Zone Research (China)

Cities in east China coast have grown explosively in both number and size during the past several decades. Mapping results from satellite images indicated a vibrant urban sprawl from 2000 to 2004 with a growth rate of 74% while the expansion has slowed down to 40% from 2004 to 2009. Average urban land price in our study areas has increased 5 times during the same time period. Results of correlation and linear regression analyses suggested that rapid increase in GDP in our study area led to accelerated urban expansion, which was further promoted by the rising urban land price. Urban encroachment of agricultural land would potentially threat China's food security as eastern coastal region is one of the most productive agriculture regions in China. Wise policies are thus needed to better curtain urban development in east China coast.

9610-29, Session PWed

Evaluation of WRF physics and cumulus parameterization schemes in simulating convective precipitation over Yangtze River Delta

Yu Kan, Chaoshun Liu, Yan-an Liu, East China Normal Univ.

(China)

In order to study the impact of the parameterization schemes in the WRF model on rainstorm

simulations, a heavy rainfall on 13 September 2013 in Yangtze River Delta, China is simulated.The study was carried out with three cumulus parameterization schemes (KF, BMJ, and GD) and three physics parameterization schemes (Lin et al, WSM5 and WSM6 scheme) under a horizontal resolution of 4km. The results indicated that the Lin et al scheme, coupled with the Beetts-Miller-Janjie(BMJ) scheme, can accurately simulate the location and intensity of the heavy rainfall. The results of an analysis of temperature ,humidity and wind speed also indicated that this scheme can accurately simulate the reality of the rainfall.Generally, when coupled with the Beetts-Miller-Janjie(BMJ) scheme, this scheme is more accurate in simulating rainstorms in Yangtze River Delta.

9610-30, Session PWed

A soil heavy metal source apportionment method based on GIS

Cheng C. Fu, Chinese Academy of Sciences (China); Zhiqiang Gao, Bo H. Zhang, Shui Q. Lu, Institute of Geographic Sciences and Natural Resources Research (China)

It's an important work to analysis the soil heavy metal sources accurately and quantitatively to control and prevent heavy metal pollution in soil. In this study, a new method of soil heavy metal source apportionment based GIS was raised and discussed. The investigation of 109 soil samples was carried out in 2012 in Zhetang Town, Nanjing, and then As, Cr, Cu, for Hg, Ni and Zn was analyzed in laboratory. Using spatial-temporal variation and pollution assessment data, taking artery, river, factory and town as the most influential factors, the sources of soil heavy metals was obtained by GIS spatial analysis technology. In order to verify its feasibility, the mathematical analysis method was also carried out. The result showed that: the contribution of four factors of As were: 28%, 7%, 21% and 45%; the contribution of four factors of Cr were: 22%, 0%, 77% and 1%; the contributions of four factors of Cu were: 28%, 11%, 38% and 23%; the contributions of four factors of Ni were: 23%, 7%, 46% and 24%; the contributions of four factors of Zn were: 27%, 9%, 53% and 11%. The two methods drew a consistent conclusion, so the soil heavy metal source apportionment method based GIS is reliable and feasible.

9610-31, Session PWed

A tool for NDVI time series extraction from wide-swath remotely sensed images

Zhishan Li, Runhe Shi, Wei Gao, East China Normal Univ. (China)

Normalized Difference Vegetation Index (NDVI) is one of the most widely used indicators for monitoring the vegetation coverage in land surface. And its time series features are capable of reflecting dynamic changes of various ecosystems. Calculating NDVI via Moderate Resolution Imaging Spectrometer (MODIS) and other wide-swath remotely sensed images provide an important way to monitor large-scale NDVI spatially and temporally. However, there are some difficulties for ecologists to extract such information correctly and efficiently because of several professional processes on the original remote sensing images such as radiometric calibration, geometric correction, multiple data composition and curve smoothing. In this study, we develop an efficient and convenient online toolbox for non-remote sensing professionals who want to extract NDVI time series with a friendly graphic user interface. It is based on Java Web and Web GIS technically. Moreover, Struts, Spring, and Hibernate frameworks (SSH) are integrated in the system for the purpose of easy maintenance and expansion. Latitude, longitude and time period are the key inputs a user need to provide. Then NDVI time series are calculated automatically.

9610-32, Session PWed

Detecting harmful algal blooms using geostationary ocean color imager (GOCI) data in Bohai Sea, China

Mingzhu Xu, Institute of Geographic Sciences and Natural Resources Research (China) and Univ. of Chinese Academy of Sciences (China); Zhiqiang Gao, Institute of Geographic Sciences and Natural Resources Research (China)

Bohai Sea is a semi-enclosed inland sea with serious environmental problems. Harmful algal blooms (HABs) in Bohai Sea happen almost every year since the new century with the characteristics of pretty large area and long duration. Detecting the range of HABs in time can largely reduce economic losses and assure human safety. Remote sensing technology has the characteristics of large-scale, synchronized, rapid monitoring which is a main means to detect HABs. GOCI is the world's first Geostationary Ocean Color Imager with outstanding temporal resolution and high spatial resolution whose monitoring range include Bohai Sea. Its continuous observations increase the chance of obtaining valid data. As the red tide happens, ocean color, sea surface temperature (SST) and water-leaving radiance(LW) will changed distinct from normal sea water. So we try to use chlorophyll-a concentration, SST and several spectral indexes derived from GOCI as indicators of red tide, to find out which are better ones. Thresholds will be defined through history red tide cases studying in Bohai Sea. Valid indicators will be integrated to construct an algorithm to detect HABs. We validate the algorithm with new red tide cases in Bohai sea. Results derived from GOCI are also compared to those derived from MODIS.

9610-33, Session PWed

Spatial-temporal variability of the continental coastline in Bohai Rim

Ning Xu, Zhiqiang Gao, Yantai Institute of Coastal Zone Research (China)

Abstract

This paper is mainly focused on the continental coastline changes of Bohai Rim with a time span from 1980 to 2010. Remote sensing images of Landsat MSS, TM and ETM in the year of 1980, 1990, 2000 and 2010 were processed to extract coastlines and land use in the gap of coastline changes. Based on Remote Sensing and GIS spatial analysis techniques, the spatial and temporal changes of coastline were analyzed and the fractal dimensions of the coastlines were calculated by box-counting method. The result show that during the research period, the coastline length of the study area increased progressively and the most significant change in coastline length was found in Bohai Bay. Especially after 2000, the coastline length entered a period of rapid growth. Comparing the three sub period of the research span, a coastal reclamation is mainly focused on an urban construction and a maritime transport in the later period while focuses on aquiculture in the earlier period; the changes of continental coastline in Bohai Rim show significant temporal and spatial heterogeneity. Moreover, the fractal dimension of the coastline in Bohai Rim was increasing during the research period, however, large scale project such as ports construction, reduced tortuous degree of the coastline.

9610-34, Session PWed

Salinity and soil moisture retrieval algorithms in western Jilin province of China using passive microwave remote sensing data

Haoyang Fu, Lingjia Gu, Ruizhi Ren, Jilin Univ. (China)

Land surface features such as area, degree of salinity, soil moisture and

salinity are mainly concerned in the observation of soil salinization. Although the field measurement of land surface features may provide more accurate results, it consumes a significant amount of manpower and time. That is a limitation on monitoring the soil salinization over a large area. Spectral remote sensing data is often used to observe the saline-alkali land and further obtain the information of its area and distribution. However, it is unable to detect soil moisture and salinity of saline land using spectral remote sensing data due to its spectral properties. Passive microwave remote sensing data reflects the dielectric properties of different land surfaces. Meanwhile, permittivity has high sensitivity to changes of soil moisture and salinity. As a result, passive microwave remote sensing data can be used for retrieval of surface soil moisture and salinity of saline land. Combined with the field sample data and passive microwave data, Western Jilin Province of China was selected as the study area in this paper. Through researching and analyzing the relationships between passive microwave brightness temperature, surface permittivity, soil moisture and salinity, effective retrieval algorithms of surface soil moisture and salinity of saline land was proposed.

9610-35, Session PWed

Dynamic analysis on coastline and sea reclamation in the efficient ecological economic zone of the Yellow River Delta based on 30-years satellite data

Xiangyu Zheng, Yantai Institute of Coastal Zone Research (China); ZhiQiang Gao, Jicai Ning, Qingshui Lu, Yantai Institute of Coastal Zone Research (China)

Coastline change and coastal reclamation change is one of the major environmental geological problems in the Highly Effective Ecologcal Zone of the Yellow River Delta. Grasp the changes and characteristics of evolution has important significance to implement the strategy of sustainable development. For this reason, the Highly Effective Ecologcal Zone of the Yellow River Delta's coastline and coastal reclamation change information were extracted by the means of visual interpretation and the artificial vector method, which four remote sensing images from the 1980 to 2010 period and the coastal survey data were used. On this basis,we have drawn a deep analysis to the evolution process and driving factors.The result show that: (1) The Highly Effective Ecologcal Zone of the Yellow River Delta's coastline showed an increasing trend in this 30 years. The change direction of it's coastline is promoting to the ocean and it was mainly induced by the deposition of sediment in the Yellow River and human factors. (2) The maximum increased of it's coastline was found during the period of 2000 to 2010 and it is espically obvious in The Yellow River Delta.(3) Coastal reclamation was mainly used for the construction of port and the breeding pool. Natural and social factors together determine the evaluation of coastal reclamation.

Snow depth retrieval algorithm of saline-alkali land in western Jilin province of China using passive microwave remote sensing data

Mingbo Sun, Lingjia Gu, Ruizhi Ren, Haoyang Fu, Jilin Univ. (China)

Snow has extremely important influence to the natural environment and human activities. The research of snow depth retrieval has practical significance to the study of climate change. Jilin Province is located in the central part of Northeast China. It has a continental monsoon climate, winter is long and cold with heavy snowfall. The western region of Jilin Province is an important part of fragile ecological environment in Northeast China where the land salinization problem is particularly obvious. With the improvement of passive microwave remote sensing techniques, passive microwave data has become an important mean to retrieve snow depth. In this paper, the western Jilin province was selected as the study area. Furthermore, the two snow depth retrieval algorithms, including Chang algorithm and FY3B operational retrieval algorithm, were validated and analyzed in the study area using FY-3B/MWRI passive microwave remote sensing data. The main research focused on the analysis of the snow depth covered on saline-alkali land and the common land. Through the observation data for five consecutive years, the snow depth change trend of saline-alkali land and common land were analyzed. The effect of salinity on snow depth was further discussed. This research provides important information to evaluate the snow depth retrieval algorithm of saline-alkali land.

The application of geo-information TuPu in coastline change study: taking coastland of Shandong province as an example

Xiangyang Liu, Zhiqiang Gao, Jicai Ning, Qingshui Lu, Yantai Institute of Coastal Zone Research (China)

With 4 periods of remote sensing images as data sources, based on Geo-information TuPu analysis method, costaline change information mapping of Shandong province during the past 30 years is established using ArcGIS software, and then this kind of information was studied deeply. The conclusions are as follows: 1) During the past 30 years, costaline of Shandong province shows an incresing trend; the centre of increasing shifts eastward gradully; different areas have different increasing situations. 2) During the past 30 years, costaline change degree of Shandong province is basically stable, change fiercely areas concentrate on the Yellow River estuary while Zhaoyuan, Penglai and Longkou have a rather slow drgree. 3) From 1980 to 1990, costaline of Shandong province retreats to land quickly, draws back slowly from 1990 to 2000 while advances to sea rapidly entering into 21st century; Dongying has a backward trace for 30 years, Zhaoyuan and Laiyang have been basically unchanged, Yantai, Rizhao and Jiaonan have a obvious trend of advancing to sea.

Analysis of scaling effect on the estimation of chlorophyll content using narrow band NDVI based on radiative transfer models

Hong Wang, Runhe Shi, Pudong Liu, East China Normal Univ. (China)

This study used particular narrow band normalized difference vegetation indices(NDVIs) to compare the estimations of chlorophyll contents at foliar level and canopy level, through a large number of simulated canopy reflectance spectra with different chlorophyll contents run on PROSPECT model and SAIL model. 10 narrow band NDVIs were selected at the identified ranges that can effectively assess foliar chlorophyll content. We firstly, analyzed the sensitivities between canopy chlorophyll contents and narrow band NDVIs, and then research the indices' resisting interferences to other parameters, aiming to evaluate the adaptation of the 10 narrow band NDVIs used in assessing the canopy chlorophyll content.

Retrieving aerosol optical depth over Beijing based on Landsat8 OLI data

Lu Zhang, Runhe Shi, Long Li, East China Normal Univ. (China)

Aerosol is a significantly important factor in climate change and environmental quality, and remote sensing makes it feasible for us to do large scale aerosol monitoring. Using Operational Land Imager (OLI) images of landsat8, Aerosol Optical Depth (AOD) was retrieved over Beijing, China,

on May 15, September 4 and October 6, 2014. Look-up tables of blue and red channel were built with 6S atmospheric radiative transfer model, and the linear relationships between AOD, TOA reflectance and surface reflectance were investigated by multiple regression analyses. The AOD of dark pixels were got from OLI images by applying the regression models. After that, the spatial distribution of AOD over Beijing was figured out by using kriging interpolation method. The retrieved results were compared with AODs from ground-based measurements of AERONET. The differences between them were analyzed. It showed that when retrieved AOD using the regression models, the errors were related to the values and ranges of AOD input in the LUT. The middle values of the input AOD would have the minimum errors. From the retrieved AOD, we can find that AOD values were higher over the city areas in the middle of Beijing and lower over the forest in the northern and western Beijing. The OLI images, which have a higher resolution, can be used to reflect the detailed distributions of AOD over Beijing.

Comparative analysis of land surface emissivity (LSE) retrieval methods and the impact on the land surface temperature based on Landsat-8 thermal infrared data

Zenghui Kan, Chaoshun Liu, Wei Gao, East China Normal Univ. (China)

With the deep application of remote sensing?several algorithms have been put forward for land surface temperature retrieval?However?land surface emissivity?which is one of the significant parameters in temperature retrieval?can be calculated in various ways?In this paper, two methods for estimating LSE based on TM data were introduced, one is Van's empirical formula method and the other is the mixed pixels decomposing method. The accuracy of the results are compared by 0.01 MODIS LSE product. Based on the detailed introduction to Van's empirical formula and the mixed pixels decomposing method in computing surface emissivity , Landsat-8 thermal infrared data and the radiative transfer equation method were used to obtain the land surface temperature in Taihu region?In this paper , atmospheric parameters based on real-time atmospheric profile , which reduce the LST error brought by the atmosphere profile .Two figures were acquired?which represented the LST_RTE_JYGS and the LST_RTE_HHXY respectively . The relationship between land surface temperature and land cover was also studied. It is shown that when the two surface emissivities obtained by the algorithms above are applied to the radiative transfer equation method ?the general trend is approximately the same for the two surface temperature retrieval results .

Assessing the potential and actual productivity of winter wheat in the North China Plain by WOFOST model

Jialin Yang, Chaoshun Liu, East China Normal Univ. (China); Wei Gao, East China Normal Univ. (China) and Colorado State Univ. (United States)

This study simulated the potential and water limited yield of winter wheat in the North China Plain from 1993 to 2013 by using WOFOST model. The yield gaps between the actual and potential production in this region were analyzed at the same time. The aims are to reveal the yield potential and its spatial and temporal variation, identify the limiting factors affecting the growth process of winter wheat. The site simulated yield data of winter wheat were interpolated spatially to map the spatial distribution. The results showed that WOFOST model is applicable for simulating yield of Winter Wheat in the North China Plain. It describes crop photosynthesis in detail and is good at simulating crop potential growth. The potential production in North China Plain is about 8000kg/hm2 while present production achieves only about 60%~70% of this. So it is urgent to improving the way of management to increase the yield of Winter Wheat in the North China Plain.

9610-42, Session PWed

Validation of the OMI-TOMS and OMI-DOAS total ozone column data using ground-based observations over China

Ming-Liang Ma, Runhe Shi, Wei Gao, East China Normal Univ. (China)

Analysis of the accuracy and variability of total ozone columns (TOC) has been conducted by many studies. However, the differences between the TOC derived from Total Ozone Mapping Spectrometer (TOMS), the Ozone Monitoring Instrument (OMI), and the Total Ozone Unit on board the Chinese Feng Yun-3A, also the differences between the TOC of space-based sensors and ground-based sensors such as Brewer and Dobson in the recent ten years. The data of four Brewer and Dobson observation sites: Xianghe, Kunming, Waliguan and Longfengshan are analyzed. In this study, the accuracy of data from the ground-based observation sites and the satellite sensors are evaluated. The spatial and temporal variation trends of the total ozone columns in different areas of China are discovered.

Remote estimation of GPP in temperate grassland: implications of the uncertainty in GPP estimation in grassland using MODIS data

Shishi Liu, Huazhong Agricultural Univ. (China); Yi Peng, Wuhan Univ. (China); Nathaniel Brunsell, University of Kansas (United States); Qingfeng Guan, China Univ. of Geosciences (China)

Many studies have pointed out that remote-sensing-based GPP models provided less accurate estimations under water stress. This study analyzed grassland GPP estimated by the Temperature and Greenness (TG) model and the MODIS algorithm along the mean precipitation gradient. The evaluation of the uniform TG model and MODIS algorithm for each site/year demonstrated the variations of the accuracy of GPP estimates among different sites and years. GPP were overestimated at the driest site among three study sites, and during the dry years of the other semiarid site. Both models provide more accurate GPP estimates for the wet site and during the wet and normal years of the semiarid sites. Calibrating both models for each site/year showed that the parameters of both models varied among sites and years, especially for the TG model. The relationship between flux-tower GPP observations and (scaled EVI *scaled LST) for the TG model and the relationship between flux-tower GPP observations and (fPAR*PAR*Tmin scalar*VPD scalar) for the MODIS algorithm were different during green-up and dry-down period of grassland during the dry years at semiarid sites. This result implied that different relationships at different growing stages might be one of the major reasons for the overestimation of GPP by the TG model and the MODIS algorithm for semiarid grassland where water is a limiting resource. Both TG model and MODIS algorithm should be used with caution in the arid and semiarid grassland regions, particularly when grassland experiences drought events.

Simulation and analysis of NDVI performance based on vegetation canopy radiative transfer model

Yuyan Zeng, Runhe Shi, Pudong Liu, Jinquan Ai, Wei Gao, East China Normal Univ. (China)

this paper uses PROSAIL model to simulate vegetation canopy reflectance under different chlorophyll contents and LAI. The changes of NDVI with different LAI and chlorophyll contents are analyzed. A simulated spectral dataset was built by using PROSIAL vegetation radiative transfer model with various vegetation chlorophyll concentrations and leaf area index. Based on the dataset, the responses of NDVI to LAI were quantitatively analyzed. A sensitivity analysis indicated that NDVI had a close relationship with LAI under different chlorophyll contents. It is concluded that the vegetation canopy biochemical parameters can be estimated efficiently by using the simulated spectrum with PROSAIL model.

Changes on albedo after a large forest fire in Mediterranean ecosystems

Carmen Quintano, Univ. de Valladolid (Spain); Alfonso Fernández-Manso, Victor Fernández, Univ. de León (Spain); Elena Marcos, Leonor Calvo, Univ. de León (Spain)

Fires are one of the main causes of environmental alteration in forest Mediterranean ecosystems. Albedo varies spatially and evolves seasonally based on solar illumination. It is greatly influenced by changes on vegetation: vegetation growth, cutting/planting forests or forest fires. This work analyzes albedo variations due to a large forest fire which occurred on 19–21 September, 2012 in Northwestern Spain. From this area, a 1-year series of six albedo images were generated from Landsat 7 Enhanced Thematic Mapper (ETM+) data. Specifically we considered the total shortwave albedo, total-, direct-, and diffuse-visible, and near-infrared albedo. Nine to twelve weeks after fire, 111 field plots were measured (27 unburned plots, 84 burned plots). The relationship between albedo values and thematic class burned/unburned was evaluated by a one-way analysis de variance. Our results demonstrate that albedo changes were related to burned/unburned variable with statistical significance, indicating the importance of forestry areas as regulators of land surface energy fluxes and revealing the potential of immediately post-fire albedo for assessing burned areas. Future research, however, is needed to evaluate the persistence of albedo changes. Albedo is greatly influenced by changes on vegetation: vegetation growth, cutting/planting forests or forest fires. This work analyzes albedo variations due to a large forest fire which occurred in Northwestern Spain. A 1-year series of six albedo images were generated from Landsat 7 Enhanced Thematic Mapper data. 111 field plots were measured (27 unburned plots, 84 burned plots). The relationship between albedo values and thematic class burned/unburned was evaluated by a one-way analysis de variance. Our results demonstrate that albedo changes were related to burned/unburned variable with statistical significance, revealing the potential of immediately post-fire albedo for assessing burned areas.

Linear fractional-based filter as a pre-classifier to map surface coal mining affected area

Carmen Quintano, Univ. de Valladolid (Spain); Alfonso Fernández-Manso, Univ. de León (Spain); Eduardo Cuesta, Univ. de Valladolid (Spain)

Surface coal mining techniques extract multiple coal seams by removing an area of many square kilometers and creating serious environmental problems. Information about mining activities location and dimensions is essential for environmental applications. In this work a linear fractional-based filter is considered as pre-classifier for surface coal mining affected area estimation in three study areas in Spain. Two vegetation indexes (Normalized Difference Vegetation Index, NDVI, and Modified Soil-Adjusted Vegetation Index, MSAVI) and three reflectance bands from Landsat 7 Enhanced Thematic Mapper (ETM+) data were used as input for the proposed filter. The filtered images were classified and the accuracy of the estimates was computed by K statistic. Surface coal mining affected area perimeters measured on the ground by Global Positioning System (GPS) were used as reference truth. The results showed that the non-local filter, used as pre-classifier, allowed higher accuracy than the same inputs without filtering. A McNemar's test confirmed that such accuracy improvement had statistical significance. Surface coal mining affected areas in Spain were accurately mapped when the linear fractional-based filter proposed here was used as a pre-classifier.

Data fusion of CO2 retrieved from GOSAT and AIRS using regression analysis and fixed rank kriging

Cong Zhou, Runhe Shi, East China Normal Univ. (China)

This paper proposes an improved statistical method for fusing carbon dioxide (CO2) data retrieved from two major instruments, the Greenhouse gases Observing SATellite (GOSAT) and the Atmospheric Infrared Sounder (AIRS). These two datasets were fused to obtain CO2 concentrations near the surface, which is a region that is especially important for studies on carbon sources and sinks. Overall, the CO2 monthly average values from GOSAT are all lower than those from AIRS from 2010 to 2012. The datasets show the similar seasonal cycles of carbon dioxide and show an increasing trend with a determination coefficient of 0.45. The analysis of the relationship between the climatic factors and the CO2 reveals that wind is the most significant contributing factor. A strong correlation was determined by adding the climatic factors as independent variables for regression analysis. The correlation coefficients between the CO2 values from AIRS and GOSAT significantly increased in response. The true CO2 data processes were then predicted using the fixed rank kriging method. This showed that the data-fusion CO2 product provides more reasonable information and that the corresponding mean squared prediction errors are smaller than those from the single GOSAT CO2 dataset.

Study on relationship between concentration of air pollution and meteorological factor in Shanghai from 2013-2014

Jing Wang, Runhe Shi, East China Normal Univ. (China)

To explore relationship of concentrations of SO2, NO2 and PM10 in the air with temperature, air pressure and relative humidity. The correlated relationship of concentration of atmospheric pollutant with meteorological element was analyzed by multiple stepwise regression.

The air concentration of SO2 was associated with the daily max atmospheric pressure,the increasing air pressure was profit to the increasing concentration of SO2,The changes of SO2 showed significantly associated with relative humidity. The air concentration of NO2 revealed to be significantly positive association with the daily max atmospheric pressure, while negative association with the daily max air temperature and the daily average relative humidity. The air concentration of PM10 showed positive correlation with the daily average atmospheric pressure, while negative association with daily average relative humidity and and the daily min relative humidity.

Optical methods for control of aquatic plants under pollutant effect

Elena V. Timchenko, Larisa A. Zherdeva Taskina, Pavel E. Timchenko, Anna A. Asadova, Samara State Aerospace Univ. (Russian Federation)

Monitoring of aquatic plants by the action of various pollutants such as synthetic surface active agents (surfactants), heavy metals and agricultural emissions (different types of fertilizers) using the methods of Raman spectroscopy (RS) and confocal fluorescence microscopy was carried out.

Stand of Raman spectroscopy is made on the basis of high-resolution digital spectrometer Shamrock sr-303i with a built-in cooling camera DV420A-OE. Confocal fluorescence microscopy was performed on the basis of an inverted microscope Olympus IX71, confocal scanner Yokogawa CSU-1 with camera EMCCD iXon Andor.

The dependence of the optical parameters of aquatic plants on the concentration of pollutants experimentally established. Shown, that the under the action of pollutants changes the intensity of the Raman wavenumber at 740 cm-1 and 1522 cm-1, which are associated with a change in the concentration of chlorophyll and carotenoids.

Shown, that the under the influence of pollutants on plant tissue occurs Raman intensity decrease by 70% at wavenumber 740 cm-1, 1522 cm-1, responsible for the C=C stretching vibration in chlorophylls and carotenoids.

This feature corresponds to the “washout pigments” from plant cells and changes in the concentration of chlorophyll and carotenoids.

Introduced optical factor that determines the impact of pollutants on plants, defined as the ratio of the intensities of the Raman scattering at wave numbers 740 cm-1, 1522 cm-1 and 1435 cm-1, corresponding to a change in the concentration of chlorophyll, ν(C = C) in b-carotene and arginine.

Microscopically, it is proved that the mechanism of degradation of chlorophyll in the presence of surfactants associated with the solubilizing of membrane proteins and the change of its permeability.

Retrieval of water and heat flux based on fusion of LANDSAT TM/ETM+ and MODIS data

Jicai Ning, Yantai Institute of Coastal Zone Research (China); Zhiqiang Gao, Yantai Institute of Coastal Zone Research, Chinese Academy of Sciences (China)

The Moderate Resolution Imaging Spectroradiometer (MODIS) data has a high temporal resolution, which, at present, is an ideal data source in simulative monitoring of regional-scale changes in surface energy and water. However, the spatial resolution of its thermal infrared band is relatively low (1 km). The Landsat TM/ETM+ data have a high spatial resolution, but their single thermal infrared bands can lead to the fact that the inversion accuracy for the surface temperature is not high, and that the time resolution is low. This limits its application in the surface evapotranspiration (ET) monitoring. Combining TM/ETM + visible wave band with MODIS thermal infrared wave band, this paper discusses a multi-scale remote sensing method to estimate regional surface ET. On the basis of space enhancement method, the vegetation index estimated by TM/ETM + enhances the surface temperature scale with the inversion of MODIS to a 30 m resolution, which aims to improve the estimation accuracy of ET in the non-uniform surface mixed-pixel. The results show that this method has a higher accuracy of ET estimation compared with the method of only using MODIS or ETM+ data. Moreover, it can obtain a more obvious effect on scale correction in the uneven land surface or various surface covering types, and the corrected ET is close to the observation result.

9611-1, Session 1

Compact wide swath imaging spectrometer (CWIS): alignment and laboratory calibration

Byron E. Van Gorp, Pantazis Mouroulis, Robert O. Green, Daniel W. Wilson, Jose I. Rodriguez, Elliot Liggett, Jet Propulsion Lab. (United States)

The Compact Wide Swath Imaging Spectrometer (CWIS) is a pushbroom imaging spectrometer for the solar reflected spectrum (380-2500 nm) with wide swath (1600 elements), fast optical speed (F/1.8), and high uniformity (≥95%). CWIS is currently under development at the Jet Propulsion Laboratory and is intended to address the need for high signal to noise ratio compact imaging spectrometer systems for the visible short wave infrared wavelength range. We give an overview of the instrument functionality, describe progress in spectrometer alignment and system integration and report laboratory data that include spatial, spectral and radiometric calibration.

9611-2, Session 1

Snow and water imaging spectrometer (SWIS): opto-mechanical and system design for a CubeSat-compatible instrument

Holly A. Bender, Pantazis Mouroulis, Byron E. Van Gorp, Jet Propulsion Lab. (United States); Christopher D. Smith, ATK Aerospace Systems (United States); Michael Eastwood, Ernesto Diaz, Colin H. Smith, Jet Propulsion Lab. (United States)

The Snow and Water Imaging Spectrometer (SWIS) is a fast, high-uniformity, low-polarization sensitivity imaging spectrometer and telescope system designed for integration in a 6U CubeSat. Operating in the 350-1700nm spectral region with 5.7nm sampling, SWIS is intended to address critical science in two localized regions of the Earth: coastal zones and snow/ice covered mountains. We discuss progress in the SWIS opto-mechanical design, thermal analysis, and mission plan. We also describe an on-board calibration system capable of addressing the stringent radiometric stability and knowledge these missions require. The spectrometer will feature a new Teledyne CHROMA array, optimized for high temperature operation, with a linear variable anti-reflection coating to enhance quantum efficiency and minimize backscatter.

9611-3, Session 1

Technical developments toward the pre-processing and quality assessment of the upcoming EnMAP space-based hyperspectral data

André Hollstein, Karl Segl, Christian Rogass, Luis Guanter, Helmholtz-Zentrum Potsdam Deutsches GeoForschungsZentrum GFZ (Germany)

EnMAP is a German imaging spectroscopy satellite mission with the declared goal to investigate the Earth's surface with a so far surpassing quality. The key scientific questions to which EnMAP will contribute are related to climate change impacts, land cover changes and processes, natural resources, biodiversity and ecosystems, water availability and quality, geohazards and risk management.

During the current mission preparation phase, technical developments at the GFZ Potsdam (EnMAP's scientific principal investigator) are going in two separate directions. On the one hand, several ground based validation activities are planed which will allow to assess the EnMAP instrument by technical means alternative to those considered in the Ground Segment calibration and monitoring plans. In particular, a program for the quantitative evaluation of EnMAP radiance and reflectance data and their spatial accuracy along the commissioning phase and the normal mission operation period is presented. This plan proposes ground- and scene-based techniques for product evaluation to derive characteristic deviation figures for the final EnMAP products and includes the assessment of technical parameters such as spectrometer co-registration, keystone or smile.

On the other hand is the development of pre-procseeing tools, among which is a research driven atmospheric correction scheme which allows for supervision and inclusion of additionally measured atmospheric parameters by potential end-users. This scheme will be based on the latest spectroscopic databases and accurate radiative transfer including the coupling of gaseous absorption and multiple scattering by various aerosol types and cirrus clouds. It will be made available to end-users trough the EnMAP-Box software.

9611-4, Session 1

Effect of entangled PSF/ISRF of imaging spectrometers on the retrieval of low signals over spectrally contrasting features: a case study for remote sensing of chlorophyll fluorescence

Luis Alonso, Univ. de València (Spain); Francisco Pinto, Uwe Rascher, Forschungszentrum Jülich GmbH (Germany); Jose Moreno, Univ. de València (Spain)

Imaging spectrographs records the signal by means of a bi-dimensional sensor where the spatial information is collected in one dimension while spectra is captured along the other dimension. Ideally, a monochromatic point source should produce a single pixel response. In real systems this is not the case, and the resulting signal spreads along and across the sensor matrix and the PSF and ISRF responses get entangled into a 2D monochromatic point spread function (MPSF).

Smooth spectral signals are not significantly affected. However, when spectra present neighboring bands with contrasting values, e.g. when absorption features or narrow emission peaks are resolved, the result is a transfer of energy between them that causes the high signal to decrease and the low signal to increase distorting the shape and the values.

Moreover, in regions around target edges, due to the diagonal terms in the MPSF, high signal in a band of one surface can be transferred to a neighboring band on an adjacent surface. Even very weak contributions in the PSF, in the order of 1E-4, can result in a noticeable effect that might be usually negligible, turns relevant for application where the objective is to discriminate weak signals such as vegetation's chlorophyll fluorescence.

This work presents a quantification of this effect through a theoretical analysis, a correction by means of an iterative deconvolution process and its application to the real case of HyPlant airborne hyperspectral imager for fluorescence retrieval.

9611-5, Session 1

Mapping pigment distribution in mud samples through hyperspectral imaging

Mehrube Mehrübeoglu, Cosmina Nicula, Shane W. Smith, Dustin K. Smith, Elizabeth S. Shanks, Paul V. Zimba, Texas A&M Univ. Corpus Christi (United States)

Mud samples collected from lakes and other bodies of water reveal information about the distribution of microorganisms in the local sediments. The pigment distribution associated with microorganisms can then be correlated to water and other environmental quality, which is a continuing research challenge. In this project hyperspectral imaging has been investigated as a technology to identify phototropic organisms living on sediments collected from the Texas Coastal Bend area. Hyperspectral data cubes offer both spatial and spectral data that can be used to examine organisms based on their spectral pigment profiles and spatial arrangement. High-performance Liquid Chromatography (HPLC) has been used as the ground truth for pigment content of microalgae living on the mud surface. The top pigment profiles identified through HPLC have been correlated with spectral signatures extracted from the hyperspectral data cubes of mud using Fast Fourier Transforms. Spatial distributions have also been investigated using 2D hyperspectral image processing. 2D pigment distribution maps have been created based on the highest correlation with pigments. Pigments identified using HPLC include chlorophyll (ch) a, chl b, and chl c2 in addition to the carotenoids fucoxanthin, diadinoxanthin, zeaxanthin, ?-? carotene, and lutein. Diatoms had the most abundant source of spectral signal, as indicated by the carotenoid fucoxanthin. Cyanobacteria (blue-green algae) were present as indicated by zeaxanthin and green algae by chl b and lutein.

9611-6, Session 1

Long-wavelength infrared hyperspectral data “mining” at Cuprite, NV

Steven M. Adler-Golden, Patrick F. Conforti, Lawrence S. Bernstein, Robert Sundberg, Spectral Sciences, Inc. (United States)

In recent years long-wavelength infrared (LWIR) hyperspectral imagery has significantly improved in quality and become much more widely available, sparking interest in a variety of applications involving remote sensing of surface composition. This in turn has motivated the development and study of LWIR-focused algorithms for atmospheric retrieval, temperature-emissivity separation (TES) and material detection and identification. In this paper we evaluate some algorithms for atmospheric retrieval, TES, endmember-finding and rare material detection for their utility in characterizing mineral composition in SEBASS hyperspectral imagery taken near Cuprite, NV. Atmospheric correction results using the In-Scene Atmospheric Correction (ISAC) method are compared with those from the first-principles, MODTRAN©-based FLAASH-IR method. Our covariance-whitened endmember-finding methods are observed to be very sensitive to image artifacts and cultural clutter. However, with clean data and all-natural terrain they can automatically locate and distinguish many minor mineral components, with especially high sensitivity to varieties of calcite. Not surprisingly, the major scene materials, including silicates, are best located using unwhitened techniques. Minerals that we identified in the data include calcite, quartz, alunite and kaolinite.

9611-7, Session 1

Baffling for high performance thermal imaging spectroscopy

William R. Johnson, Jonathan Mihaly, Simon J. Hook, Bjorn T. Eng, Jet Propulsion Lab. (United States)

The Hyperspectral Thermal Emission Spectrometer (HyTES) has flown on successful science and application campaigns since 2012. It currently flys on a Twin Otter aircraft at low altitude (1000m to 3000m AGL). HyTES utilizes a challenging optical design in practice, since it operates at cryogenic temperatures and has a small form factor compared to other designs. It utilizes a state-of-the-art Dyson optical configuration. The Dyson design uses a concave diffraction grating coupled to a 2-pass monolithic relay to disperse the light. It captures a 50-degree field of view in the cross track direction with 256 spectral channels between 7.5$ mu $m to 12.0$ mu $m. The instrument sensitivity per spectral channel is 0.2C. This is enough sensitivity to discriminate trace gas plumes at ambient temperature.

Recent modifications have improved the instrument performance considerably. This includes optimal cold operational alignment, improved thermal stability/control, and advanced calibration techniques. This paper describes these improvements in brief and explores secondary baffling techniques which we’ve found eliminate out-of-field radiometric gradients which contaminate the cross track imagery under subtle (~few degrees) roll maneuvers. Simulation results are shown as well as actual flight data.

9611-8, Session 1

Performance status of the AIRS instrument thirteen years after launch

Denis A. Elliott, Thomas S. Pagano, Jet Propulsion Lab. (United States)

The Atmospheric Infrared Sounder (AIRS) is a hyperspectral infrared instrument on the EOS Aqua Spacecraft, launched on May 4, 2002. AIRS has 2378 infrared channels ranging from 3.7 ? m to 15.4 ? m and a 13.5 km footprint at nadir. The AIRS is a “facility” instrument developed by NASA as an experimental demonstration of advanced technology for remote sensing and the benefits of high resolution infrared spectra to science investigations. AIRS, in conjunction with the Advanced Microwave Sounding Unit (AMSU), produces temperature profiles with 1K/km accuracy on a global scale, as well as water vapor profiles and trace gas amounts for CO2 , CO, SO2 , O3 and CH4. AIRS data are used for weather forecasting, climate process studies and validating climate models. The AIRS instrument has far exceeded its required design life of 5 years, with nearly 13 years of routine science operations that began on August 31, 2002. While the instrument has performed exceptionally well, with little sign of wear, the AIRS Project continues to monitor and maintain the health of AIRS, characterize its behavior and improve performance where possible. Radiometric stability has been monitored and trending shows better than 16 mK/year stability. Spectral calibration stability is better than 1 ppm/year. At this time we expect the AIRS to continue to perform well into the next decade. This paper contains updates to previous instrument status reports, with emphasis on the last three years.

9611-9, Session 2

Retrieved products from simulated hyperspectral infrared observations of a hurricane

Joel Susskind, NASA Goddard Space Flight Ctr. (United States)

This research uses Observing System Simulation Experiments (OSSEs) to assess the impact of higher spatial and temporal resolution soundings on hurricane forecast accuracy. The simulation experiments use as truth surface and atmospheric parameters obtained from an NOAA AOML OSSE GCM model. The model, called the nature run, was run with a 1km x 1km spatial resolution and sampled every 10 minutes over a moving limited area following the track of a severe Atlantic storm. Nature run products were sampled and averaged over sounder footprints for three instrument configurations, corresponding to 15kmx15km footprints in LEO orbit, 2kmx2km footprints in LEO, and 5kmx5km footprints sampled every hour in GEO. These colocated truth files were each used to simulate radiances for an IR instrument with AIRS spectral and radiometric characteristics. We analyzed the simulated radiance data using the AIRS Science Team Version-6 retrieval algorithm. This algorithm employs empirical Neural-Net first guess coefficients trained using observed AIRS radiances. These empirical coefficients, trained using real AIRS data, worked well using our simulated AIRS radiances, even under very cloudy conditions. Accuracy of retrievals obtained using simulated AIRS radiances with a 15 km footprint was similar to that obtained using real AIRS data. Retrieval results will be shown for all three sounding scenarios. Our simulated retrievals are currently being assessed by NOAA AOML in an OSSE study to determine the impact of advanced hyperspectral infrared sounders on hurricane forecast

improvement and assess whether this impact increases with higher spatial and/or temporal resolution.

9611-10, Session 2

Observing system simulation experiments to evaluate the potential impact of new remote sensing instruments on hurricane track and intensity forecasting

Robert M. Atlas, National Oceanic and Atmospheric Administration (United States)

Observing System Simulation Experiments (OSSEs) are an important tool for evaluating the potential impact of proposed new observing systems, as well as for evaluating trade-offs in observing system design, and in developing and assessing improved methodology for assimilating new observations. Detailed OSSEs have been conducted at NASA/ GSFC and NOAA/AOML in collaboration with Simpson Weather Associates and operational data assimilation centers over the last three decades. These OSSEs determined correctly the quantitative potential for several proposed satellite observing systems to improve weather analysis and prediction prior to their launch, evaluated trade-offs in orbits, coverage and accuracy for space-based wind lidars, and were used in the development of the methodology that led to the first beneficial impacts of satellite surface winds on numerical weather prediction. In this paper, we will summarize the NOAA Hurricane OSSE system and present results from experiments to evaluate hyperspectral data from polar and geostationary orbit as well as the application of GNSS and lidar data to hurricane prediction.

9611-11, Session 3

Design of a satellite end-to-end mission performance simulator for imaging spectrometers and its application to the ESA's FLEX/Sentinel-3 tandem mission

Jorge Vicent, Neus Sabater, Carolina Tenjo, Univ. de València (Spain); Juan Acarreta, Elecnor Deimos Space S.L.U. (Spain); María Manzano, GMV Aerospace & Defence (Spain); Juan Pablo Rivera, Univ. de València (Spain); Raffaella Franco, European Space Research and Technology Ctr. (Netherlands); Jose Moreno, Univ. de València (Spain)

The performance analysis of a satellite mission requires specific tools that can simulate the behavior of the platform; its payload; and the acquisition of scientific data from synthetic scenes. These software tools, called End-to-End Mission Performance Simulators (E2ES), are promoted by the European Space Agency (ESA) with the goal of consolidating the instrument and mission requirements as well as optimizing the implemented data processing algorithms. Nevertheless, most developed E2ES are designed for a specific satellite mission and can hardly be adapted to other satellite missions. In the frame of ESA's FLEX mission activities, an E2ES is being developed based on a generic architecture for passive optical missions. FLEX E2ES implements a state-of-the-art synthetic scene generator that is coupled with dedicated algorithms that model the platform and instrument characteristics. This work will describe the flexibility of the FLEX E2ES to simulate complex synthetic scenes with a variety of land cover classes, topography and cloud cover that are observed separately by each instrument (FLORIS, OLCI and SLSTR). The implemented algorithms allows modelling the sensor behavior, i.e. the spectral/spatial resampling of the input scene; the geometry of acquisition; the sensor noises and non-uniformity effects (e.g. stray-light, spectral smile and radiometric noise); and the full retrieval scheme up to Level-2 products. It is expected that the design methodology implemented in FLEX E2ES can be used as baseline for other imaging spectrometer missions and will be further expanded towards a generic E2ES software tool.

9611-12, Session 3

Best practices for performance modeling of imaging spectrometers

Louis Zellinger, Raytheon Space and Airborne Systems (United States)

This paper provides best practices for the spectral, spatial, and radiometric performance modeling of imaging spectrometers. We propose a set of standard terminology to use when modeling imaging spectrometers. The difference between resolution and sampling is discussed for both spatial and spectral dimensions. We also outline the calculation of various radiometric sensitivity metrics and their contrast counterparts. Modeling approaches are described for both solar reflected and thermally emitted bands. Finally, we apply our approach to an example hyperspectral sensor.

9611-13, Session 3

Analysis of a LWIR HSI design concept to mitigate the impact of optical distort

Pierre V. Villeneuve, Exelis, Inc. (United States); Eric M. Moskun, Joseph G. Shanks, John F. Silny, Raytheon Space and Airborne Systems (United States); Alan D. Stocker, DRS Sensors & Targeting Systems, Inc. (United States)

This report is a summary of a recent effort to quantify the relationship between LWIR spectral distortion and data utility. A representative model scene was generated from a high-fidelity terrain material database and a MODTRAN-predicted atmosphere. An optical distortion model was derived from a notional system design concept, specifying distortion as a 2D function across the FPA surface. A signal-processing framework was developed and used to propagate scene radiance through the system model (at high spatial resolution and high spectral resolution), one frame of data at a time. The output of this initial processing framework is a prediction of sensed radiance for a given prescription of optical distortion, with data sampled onto a representative FPA native-

pixel grid. The penultimate step is to (optionally) correct for the known spectral distortion by resampling the spectral signal at each spatial element onto consistent spectral grid. The final step is then to apply 2x2 spatial-spectral binning prior to recording to disk. This 2x2 binning step is critically important for feasibility of spectral resampling. The trade-off is between a more expensive, higher-resolution detector array versus the ability to perform signal processing data correction as part of standard on-board calibration. Final analysis results are presented as RMS spectral error (microflicks) illustrating the degree to which spectral distortion can be mitigated as part of an on-board data processing chain.

9611-14, Session 4

Experimental measurement and analysis of wavelength-dependent properties of the BRDF

Samuel D. Butler, Stephen E. Nauyoks, Michael A. Marciniak, Air Force Institute of Technology (United States)

The Bidirectional Reflectance Distribution Function (BRDF) is a quantity relating reflected radiance to incident irradiance and is dependent on incident angle, outgoing angle, and wavelength. Popular BRDF models include the microfacet model and the more complex linear systems diffraction model. The microfacet model is preferred in many applications, as it is a closed form approximation to the BRDF that is relatively straightforward to use. However, the microfacet model has the disadvantage of excluding the wavelength scaling almost entirely, other than in a Fresnel term; this does not agree with experimental measurements of the BRDF. In this paper, HeNe, CO2, and tunable quantum cascade lasers were

used to measure the BRDF at multiple incident angles and for multiple materials at several wavelengths between 3.39 μm and 10.6 μm, using a Schmitt Industries Complete Angle Scatter Instrument®. These BRDF results are compared with microfacet models and a linear wavelength scaling approximation. Results from the BRDF measurements quantify the dramatic change in the specular peak and surrounding region for a variety of materials, even after accounting for differences in Fresnel reflectance as a function of wavelength, and even for surface reflecting materials such as nickel that are resistant to oxidation. These experimental results suggest that it is necessary to modify the microfacet probability distribution function as a function of wavelength, instead of only an overall linear wavelength scaling. These results are an important step toward applying the BRDF to hyperspectral remote sensing, where wavelength dependent attributes may affect the quality of material identification.

9611-15, Session 4

Comparative study of spectral diffuse-only and diffuse-specular radiative transfer models and field-collected data in the LWIR

Dimitar M. Stoyanov, Michael A. Marciniak, Air Force Institute of Technology (United States); Joseph Meola, Air Force Research Lab. (United States)

The sensitivity of hyper-spectral remote sensing to the directional reflectance of surfaces was studied using both laboratory and field measurements. Namely, the effects of the specular- and diffuse-reflectance properties of a set of eight samples, ranging from high to low in both total reflectance and specularity, on diffuse-only and diffuse-specular radiative transfer models in the long-wave infrared (LWIR, 7-14-micron wavelength) were studied. The samples were measured in the field as a set of eight panels, each in two orientations, with surface normal pointing toward zenith and tipped at 45° from zenith. The field-collected data also included down-welling spectral sky radiance at several angles from zenith to the horizon, ground spectral radiance, panel spectral radiances in both orientations, infragold® spectral radiances in both orientations near each panel location, and panel temperatures. Laboratory measurements included spectral hemispherical, specular and diffuse directional reflectance (HDR, SDR and DDR) for each sample for several reflectance angles with respect to the surface normal. The diffuse-only radiative transfer model used the HDR data, while the diffuse-specular model used the SDR and DDR data. Both calculated spectral reflected and self-emitted radiances for each panel, using the field-collected sky radiance data to avoid uncertainties associated with atmospheric models. The modeled spectral radiances were then compared to the field-collected values to quantify differences in moving from an HDR-based model to an SDR/DDR model in the LWIR for a variety of surface-reflectance types.

9611-16, Session 4

Snapshot spectral imaging for gas cloud sensing and quantification

Nathan A. Hagen, Robert T. Kester, Ryan P. Mallery, Rebellion Photonics (United States)

While the design and performance of snapshot spectral imaging systems have undergone steady development over the last two decades, it is only recently that these systems have begun to find use in commercial applications. In the case of gas cloud imaging, snapshot collection has converted an application that was previously too light starved to be commercially viable into one that has demonstrated commercial success. We provide a summary of gas cloud imaging, how the snapshot advantage transforms the problem, and provide examples of gas quantification measurements and gas cloud detection videos.

9611-17, Session 4

Improved modeling of multiple scattering in hyperspectral BRDF of coastal sediments

Charles M. Bachmann, Rochester Institute of Technology (United States)

Approximate solutions to the Radiative transfer equation for granular media have been developed [1]. To apply these models to coastal sediments, modifications are needed to account for observed phenomenology. Laboratory studies [2] using a hyperspectral goniometer in the principal plane demonstrate that the degree of optical contrast between coastal sand constituents determines whether these models accurately predict the observed bi-directional reflectance distribution function (BRDF) as geophysical parameters such as density are varied. In [2] highly contrasting constituents (translucent quartz and opaque magnetite) lead to greater reflectance as density decreased, exactly the opposite of what is observed for more uniform sand. Field measurements using a hyperspectral goniometer have demonstrated results consistent with the laboratory measurements [3] as well as with CASI-1500 airborne hyperspectral measurements. Our study uses a new highly portable hyperspectral goniometer, the Goniometer of the Rochester Institute of Technology (GRIT), that can be used in both field and laboratory settings to provide data to examine the validity of and propose alternatives to earlier model assumptions [1] concerning multiple scatter.

9611-18, Session 4

Determining the bilirubin concentration in bruises of human skin using spectral imaging

Marta Lange, Inga Saknite, Janis Spigulis, Univ. of Latvia (Latvia)

The aim of this research is to determine bilirubin concentration difference in the bruises of human skin, to estimate it in order to define when exactly the bruise was made or how old it is. It is very important aspect in forensic medicine where usually the assessment of the victim is done only with visual methods and experience by the medical doctor.

The instruments used in the study are multi-spectral camera and specially custom-made device with RGB optical radiation and later MatLab program to analyze the images of the bruises to assess bilirubin concentration in time.

The idea is based on the fact that image cube of the bruise is captured at different light wavelengths, taking into account that the bilirubin absorption peak is from 400..500 nm. Then the image stack is analyzed using an algorithm where the image of the healthy skin is used as a reference and the maps of chromophores of human skin: oxyhemoglobin, deoxyhemoglobin, melanin and bilirubin are calculated and imaged.

The acquired data gives a great investment in bilirubin concentration statistical estimation, taking into account that more than 400 images of bruises were taken and analyzed of various parts of the body where the properties of bruising differ. After the analysis it is possible to conclude the age of the bruise.

This research mainly will benefit forensic medicine where currently in Latvia

the only non-invasive method for bruise assessment is the visual assessment method by the medical doctor or an expert.

9611-19, Session 4

A comparative study of three vision systems for metal surface defect detection

Mehrube Mehrübeoglu, Petru-Aurelian Simionescu, Shawn Robinson, Texas A&M Univ. Corpus Christi (United States); Lifford McLauchlan, Texas A&M Univ.-Kingsville (United States)

Identifying metal surface defects requires technologies that can detect surface anomalies while maintaining the parts intact. We present a comparative analysis of three vision systems to predict defects on the surfaces of aluminum castings: a hyperspectral imaging system, thermal imager, and digital color camera have been used to inspect the metal surfaces. Hyperspectral imaging provides both spectral and spatial information. Each material produces specific spectral signatures which are also affected by surface texture. The thermal imager detects infrared radiation whereby hotspots can be investigated to identify possible trapped inclusions close to the surface, or other superficial defects. Finally, digital color images show apparent surface defects that can also be viewed with the naked eye but can be automated for fast and efficient data analysis. The surface defect locations are analyzed and predicted using the three systems, and verified by tensile testing. Tensile testing results in the breakage of the aluminum castings, thus identifying the defective or weakest areas in the metal. This paper provides a comparative analysis of results and benefits of the three technologies.

9611-20, Session 4

Relating water absorption features to soil moisture characteristics

Jia Tian, William Philpot, Cornell Univ. (United States)

Spectral reflectance of three soil samples – selected to represent a range of particle size distribution, texture, and drying characteristics – was monitored as the samples progressed from fully saturated to air dry. Band depths of water absorption features in the near and shortwave infrared were then used as indicators of the surface water content. The change in band depth at 1930 nm reached a maximum coincident with the transition from a constant to a slowing evaporation rate and coincided with a trace amount of water in the pore spaces, consistent with the transition in drying rates.

9611-21, Session 4

Application of imaging spectrometer in gas analysis by Raman scattering

Duluo Zuo, Anlan Yu, Zhe Li, Xingbing Wang, Huazhong Univ. of Science and Technology (China); Youhui Xiong, Wuhan Cubic Optoelectronics Co., Ltd. (China)

Spontaneous Raman scattering is an effective technique in the analysis of gas composition, but the detection of minor components is difficult because of the low signal level and the usually existed background. Imaging spectrometer can provide highly spatial resolved spectra, so it should be much easier to pick up Raman signal of minor components from the Raman/fluorescence background of the sample cell and transporting optics compared with the widely used fiber-coupled spectrometers. For this reason, an imaging spectrometer was constructed from transmitting volume holographic gratings, camera lens and CCD detector. When it was used to analyze the gas sample in silver-plated capillary, which is a sample cell believed with 100-fold higher enlargement of Raman signal, the background was compressed obviously. When it was used to analyze the gas sample in a sample cell including a parabolic reflector, only weak background signal was observed, as the wide separation between the gas-signal-collecting area (the focus spot of the detecting laser beam) and the wall of sample cell benefitted in the analysis by imaging spectrometer. By using the last sample cell, the signal from CO2 in ambient air can be observed in an exposure time less than 200 sec, and the signal from minor gas component in the level of 10 ppm can also be observed in a longer exposure. These results show that an imaging spectrometer paired with a well-arranged sample cell will lower the detecting limit effectively.

9611-22, Session 5

Predicted and measured properties of single-blaze and dual-blaze diamond-ruled Offner gratings for VIS-SWIR

Mohammad A. Saleh, Patrick Woodman, Lovell E. Comstock, Richard L. Wiggins, Corning Incorporated (United States)

The Offner spectrograph is a popular choice for hyperspectral imaging systems because of its wavelength simultaneity, excellent spatial-spectral resolution, ruggedness, and unmatched reproducibility. The quality of the data from Offner spectrographs is highly dependent on the quality of the convex diffraction grating. The grating is the primary driver of optical transmission, spectral resolution, and signal linearity. Mechanical ruling, holography, and e-beam lithography have all been used in attempts to make Offner gratings with ideal merit functions.

We relate the Offner optical transmission to the grating groove profile and optical coating. We examine theoretical diffraction efficiency for single-blazed, dual-blazed and phase-step gratings and compare to as-manufactured groove profiles and grating diffraction efficiency measurements from Corning's grating test stations. We present data for both aluminum and protected silver coatings. Coating reliability data is included.

We connect signal linearity to the surface figure and finish of the grating. Data includes surface roughness measurements, figure measurements, and the measured optical scatter transfer function. Data from dual-blaze and single blaze gratings is compared.

9611-23, Session 5

Standing wave integrated Fourier transform spectrometer for imaging spectrometry in the near infrared

Gaël D. Osowiecki, Ecole Polytechnique Fédérale de Lausanne (Switzerland); Mohammadreza Madi, Edoardo Alberti, Micos Engineering GmbH (Switzerland); Toralf Scharf, Hans Peter Herzig, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

We show the miniaturization and parallelization of a standing wave spectrometer with a long term goal of creating a compact imaging spectrometer. In our standing wave integrated Fourier transform spectrometer, light is injected with micro-lenses into several optical polymer waveguides having a mode field diameter of around 3-4 microns. A piezo actuated mirror located at the waveguide end-facet is completing the experimental setup. The spatial distribution of the standing wave intensity inside the waveguide is scattered out of the plane by a periodic metallic grating located in the evanescent field of the wave. Electron beam lithography is used for the fabrication of these metallic scattering elements. The periodic metallic grating is imaged with a CCD camera which is recording a sampled intensity of the standing wave. By moving the mirror at the end of the waveguide the sampling frequency of the intensity of the standing wave can be increased, thus a larger spectrum can be recorded. We show how this is achieved for six adjacent waveguides simultaneously at a wavelength of 794nm.

9611-24, Session 5

Straylight analysis of a hyperspectral spectrometer using non sequential ray tracing

Jinsuk Hong, Samsung Thales Co., Ltd. (Korea, Republic of)

The designed hyperspectral spectrometer consists of two spectral channels, which are VNIR and SWIR. Both of the channels share same entrance slit, beam splitter and fore optics. Due to the co-registration requirement of the system, Slit length and width are slightly different according to the channel. Also, manufactured grating also can generate unwanted ray path. We investigate the straylight effect to evaluate the possibility to degrade the system performance. We confirmed the straylight effect and designed the baffle to minimize the effect.

9611-25, Session 5

Bae systems small form factor long wave infrared hyperspectral imager

John MacEachin, Michael J. Russo, BAE Systems (United States)

BAE Systems has developed a Small Form Factor (SFF) Long Wave Infrared (LWIR) Hyper-Spectral Imager (HSI). The Offner-based imager, developed through Internal Research and Development (IRAD) funding, incorporates design features that result in a substantially reduced Size, Weight, Power and Cost (SWaP-C) system that can be hosted on a wide variety of platforms. Predicted performance of the environmentally robust system is comparable to the most advanced LWIR HSI systems operating today and is achieved through a careful design approach. The optics project a nearly spatial and spectral distortion-free image onto a specially-designed Focal Plane Assembly (FPA). In addition, the mechanical configuration effectively limits background emission from noise sources, crucial to imaging in spectral clutter-limited conditions, yet avoids being overly complex as some competing technologies.

9611-26, Session 5

Smart CMOS sensor for wideband laser threat detection

Craig R. Schwarze, OPTRA, Inc. (United States); Sameer Sonkusale, Tufts Univ. (United States)

The proliferation of lasers has led to their widespread use in applications ranging from short range standoff chemical detection to long range Lidar sensing and target designation operating across the UV to LWIR spectrum. Recent advances in high energy lasers has renewed the development of laser weapons systems. The ability to measure and assess laser source information is important to both identify a potential threat as well as determine safety and nominal hazard zone (NHZ). Laser detection sensors are required that provide high dynamic range, wide spectral coverage, pulsed and continuous wave detection, and large field of view. OPTRA, Inc and Tufts have developed a custom ROIC smart pixel imaging sensor architecture and wavelength encoding optics for measurement of source wavelength, pulse length, pulse repetition frequency (PRF), irradiance, and angle of arrival. The smart architecture provides dual linear and logarithmic operating modes to provide 8+ orders of signal dynamic range and nanosecond pulse measurement capability that can be hybridized with the appropriate detector array to provide UV through LWIR laser sensing. Recent advances in sputtering techniques provide the capability for post-processing CMOS dies from the foundry and patterning PbS and PbSe photoconductors directly on the chip to create a single monolithic sensor array architecture for measuring sources operating from 0.26 – 5.0 microns, 1 mW/cm2 – 2 kW/cm2.

9611-27, Session 5

Propagation of spectral characterization errors of imaging spectrometers at level-1 and its correction within a level-2 recalibration scheme

Jorge Vicent, Neus Sabater, Univ. de València (Spain); Christophe Miesch, Airbus Defence and Space (France); Stefan Kraft, European Space Operations Ctr. (Germany); Jose Moreno, Univ. de València (Spain)

The uncertainties in the knowledge of the Instrument Spectral Response Function (ISRF), barycenter of the spectral channels and bandwidth / spectral sampling (spectral resolution) are important error sources in the processing of satellite imaging spectrometers within the narrow atmospheric absorption bands. The exhaustive laboratory spectral characterization is a costly engineering process that differs from the instrument configuration in-flight given the harsh space environment and harmful launching phase. The retrieval schemes at Level-2 commonly assume a Gaussian ISRF, leading to uncorrected spectral stray-light effects and wrong characterization and correction of the spectral shift and smile. These effects produce inaccurate atmospherically corrected data and are propagated to final Level-2 mission products. Within ESA's FLEX satellite mission activities, we have analyzed the impact of the ISRF knowledge error and spectral calibration at the Level-1b products and its propagation to the Level-2 retrieved chlorophyll fluorescence. A spectral recalibration scheme has been implemented at Level-2 reducing the spectral calibration errors in the Level-1b products down to 1-2% within the Oxygen absorption bands and enhance the quality of the retrieved products. The work presented here will show how the minimization of the spectral calibration errors requires an effort both from the laboratory characterization and from the implementation of specific algorithms at Level-2.

9611-28, Session 5

The CHROMA focal plane array: a large-format, low-noise detector optimized for imaging spectroscopy

Bradley Jones, Steven G. Bernd, Jason Herring, Jianmei Pan, Ryan S. Ries, Brian Starr, Donald L. Lee, James W. Beletic, Teledyne Imaging Sensors (United States); Elliott Liggett, Jet Propulsion Lab. (United States)

The CHROMA (Configurable Hyperspectral Readout for Multiple Applications) is an advanced Focal Plane Array (FPA) designed for visible-infrared imaging spectroscopy. CHROMA has been delivered for use in several airborne imaging spectroscopic instruments and is planned in many instrument and mission proposals. CHROMA has a pixel pitch of 30 microns and is available in array formats ranging from 320?480 to 1600?480 pixels with a range of full well sizes that allow CHROMA to be used for VSWIR, MWIR and LWIR applications. Users typically install CHROMA in pushbroom slit spectrographs and disperse spectra down the 480 pixel-length columns with the cross-scan (spatial) direction spread over the n?160 pixel-length rows, where n=2, 4, 8, 10. The CHROMA readout integrated circuit (ROIC) has correlated double sampling (CDS) in pixel, and generates its own internal bias signals and clocks. There is one analog output port, operating at 10 MHz, for every 160 columns of the array. The full frame (480 rows) readout rate is 125 Hz with 250 Hz frame rate achieved for the 240 row readout that is typical of VSWIR applications.

This paper presents the latest performance results of the CHROMA array including results of recent radiation tests. In addition, the paper will discuss progress made in additional features including: FPA (focal plane array) packaging, linear variable anti-reflection (LVAR) coating, lower noise focal plane electronics, and the potential of a future digital CHROMA with analog-to-digital converters (ADCs) on-chip.

9611-29, Session 5

Advanced space Cryocoolers for imaging spectrometry

Ted Conrad, Brian Schaefer, Lowell A. Bellis, Ryan Yates, Michael Barr, John F. Silny, Raytheon Space and Airborne Systems (United States)

Over the last several years, Raytheon has made significant advances on two long-life cryocoolers suitable for future imaging spectrometer missions. The first is the Low-Temperature Raytheon Stirling / Pulse Tube 2-stage (LT-RSP2) hybrid cryocooler, which is capable of providing simultaneous cooling at 55 K and 10 K nominal first and second stage temperatures. The LT-RSP2 also has the unique ability to shift cooling capacity between its stages, allowing it to adjust to changing load conditions and independently control both of its stage temperatures without hardware modifications or the addition of trim heat. The second cryocooler is the Raytheon Advanced Miniature (RAM) cryocooler, a robust single stage pulse tube cooler intended for VNIR and SWIR focal planes. It is an efficient, compact and robust cryocooler designed for long life and low exported vibration. Additionally, it incorporates mechanical, thermal, and electrical interfaces specifically designed to ease integration into optomechanical systems. In this paper, aspects of both the LT-RSP2 and RAM mechanical and thermodynamic designs will be presented as well as information regarding their capabilities and performance.

9611-30, Session 6

Measurement and modeling of longwave infrared directional downwelling spectral radiance

Nathan P. Wurst, Joseph Meola, Air Force Research Lab. (United States); David L. Perry, General Dynamics Corp. (United States)

Exploitation of longwave infrared hyperspectral imagery often requires atmospheric compensation (AC) in order to retrieve intrinsic material emissivity properties. For materials possessing subtle spectral features and those with lower emissivity, downwelling radiance plays an important role in the atmospheric compensation process. Most AC algorithms use an estimate of the total downwelling radiance integrated over the hemisphere. However, for tilted surfaces and non-nadir imaging scenarios, directional downwelling radiance information may be required. This work examines collection of directional downwelling radiance measurements using a Fourier transform infrared (FTIR) spectrometer. Specifically, work is done to determine a minimum number of angles to measure for which the remainder of the directional estimates can be estimated with minimal error through the use of simple data fitting models.

9611-31, Session 6

Nonnegative matrix factorization for efficient hyperspectral image projection

Alexander S. Iacchetta, James R. Fienup, Univ. of Rochester (United States); David T. Leisawitz, Matthew R. Bolcar, NASA Goddard Space Flight Ctr. (United States)

Hyperspectral imaging for remote sensing has prompted development of hyperspectral image projectors that can characterize hyperspectral imaging cameras and techniques in the lab. One such emerging astronomical hyperspectral imaging technique is wide-field double-Fourier interferometry. NASA's current state-of-the-art, wide-field imaging interferometry testbed (WIIT) has been characterized by NASA's calibrated hyperspectral image projector (CHIP), but test scenes of complicated polychromatic astronomical sources have yet to be measured with WIIT, needed to provide a more complete understanding of wide-field double-Fourier interferometry. Given enough time, CHIP can precisely synthesize a projected field containing numerous spectrally varying targets; however, it would require a very lengthy data collection process. For accurate but time-efficient projection of complicated hyperspectral images with CHIP, the field must be decomposed both spectrally and spatially in a way that provides a trade-off between accurately projecting the image and the duration of data collection. We apply nonnegative matrix factorization (NMF) to decompose hyperspectral astronomical fields into so-called eigenspectra and eigenimages that allow time-efficient projection with CHIP. Included is a brief analysis of NMF parameters that affect accuracy, including the number of eigenspectra and eigenimages used to approximate the hyperspectral image to be projected. For the chosen field, the normalized mean squared synthesis error is under 1% with just 8 eigenspectra. NMF of hyperspectral astronomical fields better utilizes CHIP's capabilities, providing time efficient and accurate representations of astronomical scenes to be imaged with WIIT.

9611-32, Session 7

Comparison of hyperspectral change detection algorithms

Michael L. Pieper, Dimitris G. Manolakis, MIT Lincoln Lab. (United States); Thomas W. Cooley, Air Force Research Lab. (United States); Michael S. Brueggeman, Andrew J. Weisner, John Jacobson, National Air and Space Intelligence Ctr. (United States)

There are a multitude of civilian and military applications for the detection of anomalous changes in hyperspectral images. Anomalous changes occur when the material within a pixel is replaced. Environmental factors that change over time, such as illumination, will affect the radiance of all the pixels in a scene, despite the materials within remaining constant. The goal of an anomalous change detection algorithm is to suppress changes caused by the environment, and find pixels where the materials within have changed.

Anomalous change detection is a two-step process. Two co-registered images of a scene are first transformed to maximize the overall correlation between the images, and then an anomalous change detector is applied to the transformed images. The transforms maximize the correlation between the two images to attenuate the environmental differences that distract from the anomalous changes of importance. Several categories of transforms with differing optimization parameters are discussed and compared.

We apply one of two types of anomalous change detectors to the transformed images. The first anomaly (AD) uses the difference of the two transformed images. The second concatenates the spectra of two images and uses an aggregated AD. A comparison of the two anomaly detection methods and their effectiveness with the different transforms is done for the first time.

9611-33, Session 7

Ultrafast high accuracy radiative transfer modeling of cloudy atmosphere in solar spectral region

Qiguang Yang, Xu Liu, NASA Langley Research Ctr. (United States); Wan Wu, Science Systems and Applications, Inc. (United States); Ping Yang, Chenxi Wang, Texas A&M Univ. (United States)

An ultrafast radiative transfer model has been developed at NASA Langley research center for simulating the radiance and relfectance at top of atmosphere (TOA). Both thermal and solar contributions are included in our model in the wavenumber range from 1800 cm-1 to 3000 cm-1. We are expanding our results to visible and UV wavelength range. The scattering properties of the cloud have been obtained using 52-stream DISORT and stored in a 3.3 GB lookup table (LUT) and three smaller LUTs. To efficiently

use these data we compressed them to less than 1% of its original size using our recently proposed algorithm. These very small LUTs were used to simulate the radiance detected by satellite. Billions of simulations indicate that the accuracy in the TOA reflectance is excellent. Compared to 52-stream DISORT, 93.3% of the over one billion off grid cases have an error in TOA reflectance smaller than 0.001. The maximum error of 0.0337 occurred at the back scattering direction. The simulation is ultrafast, it takes only about 6 ms to simulate the infrared atmospheric sounding interferometer (IASI) radiance data from 645 cm-1 to 2760 cm-1 at fixed solar and satellite angles. The solar part alone takes only 0.52 ms. The high accuracy as well as the ultrafast nature of our algorithm make it very useful for hyperspectral remote sensing.

9611-34, Session 7

Phase correction algorithms for a snapshot hyperspectral imaging system

Victoria C. Chan, The Univ. of Arizona (United States); Michael W. Kudenov, North Carolina State Univ. (United States); Eustace L. Dereniak, The Univ. of Arizona (United States)

We present image processing algorithms that improve spatial and spectral resolution on the Snapshot Hyperspectral Imaging Fourier Transform (SHIFT) spectrometer. A 10x10 lenslet array superimposes a two-dimensional (2D) interferogram onto 100 sub-images of the scene. By arranging the sub-images in increasing optical path difference, a three-dimensional (3D) interferogram cube is formed. Phase corrections are applied to the interferogram cube. Final measurements are stored in a 3D datacube containing the scene's spatial and spectral information. We discuss calibration procedures, review post-processing methods, and present preliminary results from proof-of-concept experiments.

9611-35, Session 7

Characterizing intimate mixtures of materials in hyperspectral imagery with albedo-based and kernel-based least squares and approaches

Robert S. Rand, Ronald G. Resmini, National Geospatial-Intelligence Agency (United States); David W. Allen, National Institute of Standards and Technology (United States)

Linear mixtures of materials in a scene often occur because the pixel size of a sensor is relatively large and consequently they contain patches of different materials within them. This type of mixing can be thought of as areal mixing and modeled by a linear mixture model with certain constraints on the abundances. However, there are more complex situations, such as scattering that occurs in mixtures of vegetation and soil, or intimate mixing of granular materials like soils. Such multiple scattering and microscopic mixtures within pixels have varying degrees of non-linearity. Often enough, scenes may contain cases of both linear and non-linear mixing on a pixel-by-pixel basis. This study considers two approaches for un-mixing pixels in a scene. The methods are motivated by earlier studies that indicate non-linear mixtures in reflectance space are approximately linear in albedo space. The first method converts reflectance to single-scattering albedo (SSA) according to Hapke's theory assuming bidirectional scattering at nadir look angles and uses a constrained linear model on the computed albedo values. The second method is motivated by the same idea, but uses a kernel that seeks to capture the linear behavior of albedo in non-linear mixtures of materials. The behavior of the kernel method is dependent on the value of a parameter, gamma. Both methods are dependent on the endmembers and on error metrics. This study compares the two approaches and pays particular attention to these dependencies. Both laboratory and aerial collections of hyperspectral imagery are used to validate the methods.

9611-36, Session 7

Improved atmospheric retrievals of hyperspectral data using geometric constraints

Kenneth Ewald, Ball Aerospace & Technologies Corp. (United States); Emmett J. Ientilucci, Rochester Institute of Technology (United States); John Jacobson, National Air and Space Intelligence Ctr. (United States); Alan T. Buswell, Ball Aerospace & Technologies Corp. (United States)

Under complex illumination conditions, such as urban environments or targets along a tree line, LIDAR data can be used to improve hyperspectral surface reflectance retrievals by accounting for per-pixel geometric effects, such as shadowing, surface tilt, and partial sky occlusions. The impact of individual surface illumination factors, including atmospheric transmission, path radiance, and direct solar and downwelled sky radiance, can vary based on a pixel's geometry. Therefore, it is important to accurately estimate each atmospheric term used to convert calibrated radiance to surface reflectance when including geometric effects in retrievals. This paper discusses techniques to use in-scene radiance data and LIDAR scene geometry to iterate on atmospheric parameters for improved reflectance retrievals using MODTRAN.

A Lambertian material's reflectance is invariant to illumination changes across the scene. Therefore, any instance of that material's retrieved reflectance should be equivalent when atmospheric and geometric considerations are properly taken into account. When incorrect atmospheric parameters are applied, the same material will exhibit differences in retrieved reflectance as a function of illumination. This is an important consideration, as requiring the reflectance of similar materials to be equivalent provides an additional constraint on which to solve for individual atmospheric parameters. These parameters can be iterated upon until the difference between the retrieved reflectivity for a material found under multiple unique illumination conditions is minimized. The overall improvements in retrieved reflectance will be evaluated, and the impacts of scene geometry assumptions and uniqueness of solution for the retrieved optimal atmospheric parameters will be investigated.

9611-37, Session 7

Hyperspectral band selection using the total dependence metric

Seyed Enayat Hosseini Aria, Massimo Menenti, Ben Gorte, Technische Univ. Delft (Netherlands)

One of the objectives of dimensionality reduction of hyperspectral images is to minimize the dependency among a selected bandset. It means that from a hyperspectral dataset a number of bands should be selected in such a way that a new bandset has the least redundant information. Band selection techniques, despite the feature extraction ones, prevent the original data from being compromised or distorted by a transformation such as PCA. However, the problem of selecting the most independent bands is the lack of a unique metric revealing the dependency in hyper-dimensional spaces. The common way for the selection is to compute the dependence between each pair of bands, making a dependency matrix, categorizing the bands, and selecting a representative band from each category. Eventually, as there has been no single metric to show the most independent bandset so far, classification accuracy has been used to assess the independent bandsets.

In this paper, a newly developed metric of dependency in hyper-dimensional spaces is introduced to show which band selection technique determines the best independent bandset. This measure, named Total Dependence (TD), is a function of the greatest eigenvalue derived from the absolute correlation matrix of the original dataset. Using TD, it is feasible to compare different bandsets with respect to dependence. In addition to the comparisons, TD is also used to select a bandset with the lowest dependence. Primary results over a hyperspectral vegetation scene show five selected bands using TD has much lower dependence than a well-known band selection method.

9611-38, Session 7

A novel anomaly detection approach based on clustering and decision-level fusion

Shengwei Zhong, Ye Zhang, Harbin Institute of Technology (China)

In hyperspectral image processing, anomaly detection is a valuable way of searching targets whose spectral characteristics are not known, and the estimation of background signals is the key procedure. On account of the high dimensionality and complexity of hyperspectral image, dimensionality reduction and background suppression is necessary. In addition, the complementarity of different anomaly detection algorithms can be utilized to improve the effectiveness of anomaly detection. In this paper, we propose a novel method of anomaly detection, which is based on clustering of Artificial Searching Swarm Algorithm (ASSA) and decision-level fusion. In our proposed method, bands with similar features are firstly clustered using the optimized k-means method based on ASSA. Secondly, dimensionality reduction is conducted using principle component analysis to reduce the amount of calculation. Then, to increase the accuracy of detection and decrease the false-alarm ratio, both Reed-Xiaoli (RX) and Kernel RX algorithm are used on processed image. Lastly, a decision-level fusion is processed on the detection results. A simulated hyperspectral image and a real hyperspectral one are both used to evaluate the performance of our proposed method. Visual analysis and quantative analysis of receiver operating characteristic (ROC) curves show that our algorithm can achieve better performance when compared with other classic approaches and state-of-the-art approaches.

9611-39, Session 7

An improved full automated endmember extraction algorithm based on endmember independence

Yiran Wang, Shengwei Zhong, Ye Zhang, Harbin Institute of Technology (China)

Current algorithms of endmember extraction generally need to determine the number of endmembers manually. However, the number of endmembers is unknown in practical application, so an automated and iterative endmember extraction algorithm is put forward in this paper to solve the problem. Firstly, due to the spectral information of endmember is similar with its neighbors but noise is independent with others, we analyze the relevance between pixels and endmember in the concentric sliding window centered at each test endmember in order to eliminate the influence of noise. Then, due to the independence among endmembers, a candidate set formed of endmembers which have been extracted is constructed. We compute the correlation between the new endmember and the candidates in the set each time, if the largest correlation is small; the new one is added to the set. If the new one fails to join the set directly, we can take it to replace the existed in the set to increase the distance among endmembers. Finally, if the endmembers in the set remain unchanged in a few times, the iteration stops. The experiment shows that the improved algorithm have a near accuracy of endmember extraction with the traditional algorithm, meanwhile it weakens the influence of noise on the endmember extraction.

9611-40, Session PWed

Random projection-based dimensionality reduction method for hyperspectral target detection

Weiyi Feng, Nanjing Univ. of Science and Technology (China)

Dimensionality reduction is a frequent preprocessing step in hyperspectral image analysis. High-dimensional data will cause the issue of the “curse of dimensionality” in the applications of hyperspectral imagery. In this paper, a dimensionality reduction method of hyperspectral images based on random projection (RP) for target detection was investigated. In the application areas of hyperspectral imagery, e.g. target detection, the high dimensionality of the hyperspectral data would lead to burdensome computations. Random projection is attractive in this area because it is data independent and computationally more efficient than other widely-used hyperspectral dimensionality-reduction methods, such as Principal Component Analysis (PCA) or the maximum-noise-fraction (MNF) transform. In RP, the original high-dimensional data is projected onto a low dimensional subspace using a random matrix, which is very simple. Theoretical and experimental results indicated that random projections preserved the structure of the original high-dimensional data quite well without introducing significant distortion. In the experiments, Constrained Energy Minimization (CEM) was adopted as the target detector and a RP-based CEM method for hyperspectral target detection was implemented to reveal that random projections might be a good alternative as a dimensionality reduction tool of hyperspectral images to yield improved target detection with higher detection accuracy and lower computation time than other methods.

9611-41, Session PWed

Analysis of active oxygen species kinetics

Andrey Pershin, Samara State Aerospace Univ. (Russian Federation)

Reactive oxygen species play an important role in atmospheric processes, combustion in oxygen plasma, into the active environments of lasers, etc. Pulse laser photolysis of ozone used for the electronically excited molecular oxygen, oxygen atoms and vibrationally excited ozone is often. In post-photolysis zone runs a lot of chemical and energy exchange processes involving reactive oxygen species. The paper is composed kinetic scheme of these processes and the related system of nonlinear differential equations. Obtained by both analytical and numerical solutions of the equations, which are in good agreement with the experimental dependences. The ratio of the reaction channel to a relaxation for the reaction of vibrationally excited ozone and atomic oxygen.

9611-42, Session PWed

Development and testing of an image-guided FT-IR Instrument for field spectroscopy

Xiaobing Dai, State Key Lab. for Multi-Spectral Information Processing Technologies (China) and Huazhong Univ. of Science and Technology (China); Xiangyan Liu, Huazhong Univ. of Science and Technology (China)

Standoff detection, identification and quantification of chemicals require sensitive spectrometers with calibration capabilities. We have developed a compact novel instrument that can not only provide imaging capability, bust also one that provides spectral capability of the field of view (FOV) center under the image-guided. The system employs a Fourier transform infrared (FT-IR) spectrometer, coupled with chalcogenide glass optical fiber, and a specially designed infrared optic lens. A special kit provided by Bruker Optics is connected on the spectrometer to focus the infrared beam from the lens at the entry of the fiber. Its spectral range covers the infrared band from 1870cm-1 to 5000cm-1 and its spectral resolution could be chosen among five selected values 1, 2, 4, 8, 16, 32cm-1. This paper will address the issues of image-guided spectroscopy and will show how an instrument designed for specifically imaging applications can dramatically improve the performance of the system and quality of the data acquired. The benefit of these technologies in spectroscopy can be demonstrated with a system optimally designed for detecting spectral characteristics of moving targets.

Conference 9612: Lidar Remote Sensing for Environmental Monitoring XV

SPIE. OPTICS+ PHOTONICS OPTICAL ENGINEERING+ APPLICATIONS

Wednesday - Thursday 12–13 August 2015

Part of Proceedings of SPIE Vol. 9612 Lidar Remote Sensing for Environmental Monitoring XV

9612-19, Session PWed

Parameterization of a geometrical reaction time model for two beam nacelle LIDARs

Thorsten Beuth, Maik Fox, Wilhelm Stork, Karlsruher Institut für Technologie (Germany)

The reaction time model is briefly reintroduced as published in a previous publication to explain the restrictions of detecting a horizontal homogenous wind field by two beams of a LiDAR placed on a wind turbine's nacelle that measure the line-of-sight velocity v_l and v_r in the distance l_m between an opening angle of 2?. The wind vector length V and wind angle ? can be reconstructed by ?=arctan?((f-1)/((f+1) tan??)) and V=√(u^2+v^2) with the relationship between the measured wind speeds f=v_l/v_(r) and the orthogonal components u=(v_l+v_r)/(2?cos??) and v=(v_l-v_r)/(2?sin??). In the model, the distance l_r is estimated as the minimum distance that a homogenous wind front with an angle of ? in comparison to the yaw angle has to travel between the second measuring point of a two beam nacelle LiDAR and the tip of the rotor. In a next step, this model is parameterized to get more general statements for a beneficial system design concept. This approach is based on a parameterization towards the rotor disc radius R. All other parameters, whether they are distances like the measuring length l_m or velocities like the cut-out wind speed v_co, can be expressed by the rotor disc radius R. With the consideration of the measuring frequency of the system, the computation time of the controller and the actuator reaction time, an overall reaction time can be estimated. This reaction time leads to a minimum measurement distance that the LiDAR system has to have. In the end, the requirements are matched against the commercially available LiDARs to show the necessity to advance these systems to suit the upcoming challenges of gust regulation.

9612-1, Session 1

NASA's future earth science technology capabilities: challenges and opportunities *(Keynote Presentation)*

George J. Komar, NASA Headquarters (United States)

A decade of technology investments has contributed to the current missions and the measurements for Earth Science, and these investments are based upon active sensing technologies, such as lasers and radars. The mid and far term measurement concepts and the technology developments supporting the science measurement capabilities are highlighted.

9612-2, Session 2

Progress in developing the CO2 sounder Lidar as a candidate for the ASCENDS Mission *(Invited Paper)*

James B. Abshire, Haris Riris, NASA Goddard Space Flight Ctr. (United States); Graham R. Allan, Sigma Space Corp. (United States); Jeffrey R. Chen, Anthony W. Yu, Xiaoli Sun, NASA Goddard Space Flight Ctr. (United States); Anand K. Ramanathan, Univ. of Maryland, College Park (United States)

The lidar on NASA's planned ASCENDS mission will measure atmospheric CO2 and O2 column absorption and range, allowing calculation of the atmospheric CO2 mixing ratio needed for flux estimates. The lidar approach for ASCENDS will permit, for the first time, accurate atmospheric CO2 concentration measurements to be made globally over a wide range of conditions. These include at night, at high latitudes during all seasons, through hazy and thin cloud conditions and to cloud tops. None of these are possible using passive sensors.

The CO2 Sounder team has made significant progress in developing of the CO2 Sounder approach and laser technology for the ASCENDS lidar. The team has demonstrated their airborne CO2 lidar on flights onboard the NASA DC-8 during 2010, 2011 and 2013. The results show that airborne measurements made in 2011 and 2013 were accurate to ~1 ppm for airborne altitudes between 6 and 12 km. Analysis also highlighted a new capability to measure CO2 column absorption and range both to cloud tops and the ground. Differencing the retrievals allows estimating the CO2 in the column between the ground and cloud top, which allows a direct estimate of the CO2 concentrations in the boundary layer.

The project has demonstrated several key elements needed for the space lidar. A new step-locked laser diode source and a high power fiber laser preamplifier. The high power fiber preamplifier is based on an EDFA and has produced over 350 uJ/pulse at 1572 nm. A breadboard of a laser power amplifier using an initial planar waveguide gain element has been assembled. The goal for it is to produce the 2.7 mJ/pulse needed for space. Completion is planned for late spring 2015. A new HgCdTe APD detector also developed in collaboration with DRS RSTA. Testing shows it has photon counting sensitivity, analog response, high linear dynamic range and more sensitivity than the IR-PMT detector used previously.

For the 2014 airborne campaign, the CO2 Sounder team incorporated several of these capabilities into its airborne lidar. These include the step-locked laser source and HgCdTe APD detector. Airborne measurements of column CO2 and range were made over the California Central Valley, the redwood forests along the northern California coast, and above growing agriculture in Iowa. Two flights were also made under the OCO-2 satellite track. A summary of all these results will be presented.

9612-3, Session 2

Development of double and tripled-pulsed 2-micron IPDA Lidars for column CO2 measurement *(Invited Paper)*

Upendra N. Singh, Jirong Yu, Mulugeta Petros, Tamer F. Refaat, Ruben G. Remus, NASA Langley Research Ctr. (United States); Karl Reithmaier, Science Systems and Applications, Inc. (United States)

Carbon dioxide (CO2) is an important greenhouse gas that significantly contributes to the carbon cycle and global radiation budget on Earth. CO2 role on Earth's climate is complicated due to different interactions with various climate components that include the atmosphere, the biosphere and the hydrosphere. Although extensive worldwide efforts for monitoring atmospheric CO2 through various techniques, including in-situ and passive sensors, are taking place high uncertainties exist in quantifying CO2 sources and sinks. These uncertainties are mainly due to insufficient spatial and temporal mapping of the gas. Therefore it is required to have more rapid and accurate CO2 monitoring with higher uniform coverage and higher resolution. CO2 DIAL operating in the 2-?m band offer better near-surface CO2 measurement sensitivity due to the intrinsically stronger absorption lines. For more than 15 years, NASA Langley Research Center (LaRC) contributed in developing several 2-?m CO2 DIAL systems and technologies. This paper focuses on the current development of the airborne double-pulsed and triple-pulsed 2-?m CO2 integrated path differential absorption (IPDA) lidar system at NASA LaRC. This includes the IPDA system development and integration. Results from ground and airborne CO2 IPDA testing will be presented. The potential of scaling such technology to a space mission will be addressed.

9612-5, Session 2

Optical parametric technology for methane measurements

Martha W. Dawsey, NASA Goddard Space Flight Ctr. (United States); Kenji Numata, Univ. of Maryland, College Park (United States); Stewart T. Wu, Haris Riris, NASA Goddard Space Flight Ctr. (United States)

Atmospheric methane (CH4) is the second most important anthropogenic greenhouse gas, with approximately 25 times the radiative forcing of carbon dioxide (CO2) per molecule. Yet, lack of understanding of the processes that control CH4 sources and sinks and its potential release from stored carbon reservoirs contributes significant uncertainty to our knowledge of the interaction between carbon cycle and climate change.

At Goddard Space Flight Center (GSFC) we have been developing the technology needed to remotely measure CH4 from orbit. Our concept for a CH4 lidar is a nadir viewing instrument that uses the strong laser echoes from the Earth's surface to measure CH4. The instrument uses a tunable, narrow-frequency light source and photon-sensitive detector to make continuous measurements from orbit, in sunlight and darkness, at all latitudes and can be relatively immune to errors introduced by scattering from clouds and aerosols.

Our measurement technique uses Integrated Path Differential Absorption (IPDA), which measures the absorption of laser pulses by a trace gas when tuned to a wavelength coincident with an absorption line. We have already demonstrated ground-based and airborne CH4 detection using Optical Parametric Amplifiers (OPA) at 1651 nm using a laser with approximately 10 μJ/pulse. However, with our optical parametric oscillator (OPO), we were able to obtain 210 μJ/pulse at 5 KHz with a narrow linewidth. Next, we will upgrade our OPO system to add several more wavelengths in preparation for our September 2015 airborne campaign, and expect that these upgrades will enable CH4 measurements with 1% precision (10-20 ppb).

9612-6, Session 2

Single frequency pulsed and continuous wave fiber lasers near 2 micron wavelength *(Invited Paper)*

Shibin Jiang, AdValue Photonics, Inc. (United States)

Single-frequency pulsed and continuous wave (CW) lasers operating in the spectral region near 2?m are highly desirable for many applications, including airborne and space-borne coherent lidar for atmospheric sensing, and nonlinear frequency conversion for the generation of narrow-band mid-infrared radiation. Although high-power pulsed single-frequency Tm- or Ho-doped crystal lasers have been demonstrated decades ago, they suffer from a complicated free-space laser cavity design with a concern of its long-term reliability. Fiber-based laser sources are much more reliable and more suitable for these applications, especially for their field deployment.

In this paper we will present our demonstration of CW single frequency fiber laser with narrow linewidth using Tm doped and Tm/Ho-co-doped fibers, all-fiber Q-switched single-frequency laser oscillator near 2 micron, and modulated single frequency fiber lasers. Pulse energy of 0.5mJ and average power of 15W were demonstrated by using our innovative large mode field diameter polarization maintaining gain fibers, which enable many new applications.

9612-7, Session 2

Monolithic high power semiconductor seed lasers near 2.05 ?m

Mahmood Bagheri, Clifford Frez, Ryan Briggs, Siamak Forouhar, Jet Propulsion Lab. (United States)

We report on the development and demonstration of a compact 2-μm semiconductor laser. Our monolithic fiber-pigtailed semiconductor seed laser will greatly enhance the operability and applicability of IPDA lidar systems for high spatial and temporal resolution CO2 airborne measurements as well as future Earth-orbiting CO2 measurement missions. The frequency agility and multi-format modulation capability of the proposed technology, its small size and compatibility with standard DFB lasers at the telecom band paves the way for adoption of the attractive 2.05 ?m CO2 band in the already demonstrated lidar systems operating at the 1.57 ?m band. Furthermore, the large tuning range of the proposed semiconductor laser (>150 GHz), and their high speed modulation capability at moderate power consumption (<2 W) would enable unprecedented high vertical range-finding resolution on lidar systems and would greatly enhance the performance of current lidar systems operating at 2.05 ?m that utilize solid-state crystal lasers.

The large mode-hop free tuning range of these lasers covers multiple CO2 absorption lines. The current tuning capability enables a variety of high-speed frequency sequencing and switching formats. This is important for high precision CO2 lidar measurement schemes that require near-simultaneous measurements at multiple wavelengths in the vicinity of the target absorption line in order to infer column CO2 concentration.

9612-8, Session 3

Laser transmitter development for NASA's Global Ecosystem Dynamics Investigation (GEDI) Lidar *(Invited Paper)*

Donald B. Coyle, Paul R. Stysley, NASA Goddard Space Flight Ctr. (United States); Demetrios Poulios, Greg B. Clarke, Richard B. Kay, American Univ. (United States)

The Global Ecosystems Dynamics Investigation (GEDI) Lidar, to be installed aboard the International Space Station in early 2018, will use 3 NASA-developed laser transmitters to produce 14 parallel tracks of 25 m footprints on the Earth's surface. The High Output Maximum Efficiency Resonator (HOMER) diode pumped Nd:YAG laser is an oscillator-only design, producing 17 mJ pulses at 240 Hz with TEM00 12 ns pulses. The unstable resonator uses gaussian optics and thermal lensing compensation to achieve an aperture-free, TEM00 cavity with a side pumped zigzag Nd:YAG slab, typical in amplifier staging but not 4W oscillators. This basic concept allowed us to high efficiency and long lifetime, while keeping complexity and costs down. Also critical to the HOMER laser success is the minimal part count, high diode derating and low intracavity fluence. Achieving a long duration laser instrument is a GEDI priority and has been the focus of numerous efforts over the years. The 3 HOMER lasers will be used in combination with active electro-optic transmit beam dithering and diffractive optics to achieve the 16 Billion laser footprint pattern on the Earth. We were careful to keep the risk low by using only high TRL (technology readiness level) components and technologies where ever possible, and worked extensively to remove opto-mechanical distortions from impacting the relatively long (40 cm) cavity. Even with access to the Japanese Experiment Module (JEM) liquid cooling loop, the laser will see wide swings in temperatures, and thus, removing temperature dependent performance is a priority.

9612-9, Session 3

UV lifetime laser demonstrator for space-based applications

Floyd E. Hovis, Michael Albert, Kent Puffenburger, Tom Schum, Fran Fitzpatrick, Slava Litvinovitch, Joe Rudd, Fibertek, Inc. (United States)

A long-lived UV laser is an enabling technology for a number of high-priority, space-based lidar instruments. These include a next generation cloud and aerosol lidar that incorporates a UV channel, a direct detection 3-D wind lidar, and an ozone DIAL system. In previous SBIR funded work

we developed techniques for increasing the survivability of components in high power UV lasers and demonstrated improved operational lifetimes. In this Phase III ESTO funded effort we are designing and building a TRL 6 demonstrator that will have increased output power and a space-qualifiable package that is mechanically robust and thermally-stable. For full space compatibility, thermal control will be through pure conductive cooling. Contamination control processes and optical coatings will be chosen that are compatible with lifetimes in excess of 1 billion shots. The demonstration laser will incorporate a diode-pumped, single-frequency, Nd:YAG master oscillator and three diode pumped amplifier stages capable of providing over 250mJ per pulse of 1064nm light at 150Hz. The 1064nm output will be frequency tripled to provide greater than 100mJ pulses of 355nm light. After completing the laser module build in the second quarter of 2015 we will initiate lifetime, TVAC and vibration testing to demonstrate that the design is at TRL 6.

9612-10, Session 3

The cloud-aerosol transport system (CATS): a technology demonstration from the International Space Station *(Invited Paper)*

Matthew McGill, John Yorks, Stan Scott, NASA Goddard Space Flight Ctr. (United States); Andrew Kupchock, Patrick Selmer, Science Systems and Applications, Inc. (United States)

The Cloud-Aerosol Transport System (CATS) is a new instrument deployed to the International Space Station (ISS) in January 2015. The CATS instrument is a technology demonstration for laser remote sensing of clouds and aerosols. Utilizing high repetition rate lasers and photon-counting detectors, the CATS instrument is demonstrating multiple new technologies in-space. Measurements are downlinked via the near-continuous ISS communications links to be ingested in near-real time directly into aerosol forecast models.

Funded by the ISS Program as a demonstration of the operational science capability of the ISS, CATS is a low-cost approach to obtaining new science measurements while demonstrating new technologies. Development of CATS also served as a pathfinder for NASA, as it is the first NASA-developed payload for the Japanese Experiment Module-Exposed Facility (JEM-EF).

The ISS orbit is well suited to the science goals of CATS, as the ISS tracks over and along primary aerosol transport paths in the atmosphere. The science goals are to augment the CALIPSO data record for space-based lidar measurements, provide observational lidar data to improve operational aerosol models, and to demonstrate direct retrieval of aerosol extinction from space.

9612-11, Session 3

Fiber-based, carbon dioxide, laser transmitter development for space application

Mark A. Stephen, Anthony W. Yu, NASA Goddard Space Flight Ctr. (United States)

NASA's Goddard Space Flight Center (GSFC) is working on maturing the technology readiness of a laser transmitter designed for use in atmospheric CO2 remote-sensing. GSFC has been developing an airplane-based CO2 lidar instrument over several years to demonstrate the efficacy of the instrumentation and measurement technique and to link the science models to the instrument performance. The ultimate goal is to make space-based satellite measurements with global coverage. In order to accomplish this, we must demonstrate the technology readiness and performance of the components as well as demonstrate the required power-scaling to make the link with the required signal-to-noise-ratio (SNR). To date, all the instrument components have been shown to have the required performance with the exception of the laser transmitter.

In this program we are working on a fiber-based MOPA laser transmitter architecture where we will develop a ruggedized package and perform the relevant environmental tests to demonstrate TRL-6. In this paper we will review our transmitter architecture and progress on the performance and packaging of the laser transmitter.

9612-12, Session 4

Lidar investigations of atmospheric dynamics and structure *(Invited Paper)*

C. Russell Philbrick, Hans D. Hallen, North Carolina State Univ. (United States)

Ground based lidar using Raleigh and Raman scattering, differential absorption (DIAL), and resonance fluorescence techniques are capable of providing unique signatures to study active atmospheric dynamical processes. Excellent measurements of structure in the lower atmosphere are available in time sequences of water vapor profiles from Raman and DIAL lidar. For example, water vapor profiles show the scale and motion of daytime convection cells, residual layer bursts into the planetary boundary layer (PBL), determine PBL height, study cloud formation and dissipation, observe scale size of gravity waves and turbulent eddies, as well as observe Brunt–Väisälä oscillations and Boer waves. Rayleigh lidar provide backscatter profiles in the troposphere show the PBL, but they provide more valuable temperature profiles in the stratosphere and mesosphere, where the gravity waves, stratospheric volcanic clouds and noctilucent clouds are observed. Resonance fluorescence lidar is able to profile temperature 80-100 km, and measure species concentration with resonance scattering signatures of meteoric dust metastable states deposited there, swept up by Earth's orbital motion. Lidar techniques provide the optimum technique for investigating atmospheric dynamics in atmospheric profile structure. Examples of several features forced by dynamical processes are selected to illustrate this and could be subjects for future focused investigations. Several future experiments are described that should improve our understanding of physical processes modifying atmospheric structure, determine the magnitudes of wavelike features, show the initiation of turbulence, and show other structure properties.

9612-13, Session 4

Two-component wind fields from single scanning aerosol lidar

Shane D. Mayor, Pierre Derian, Christopher F. Mauzey, California State Univ., Chico (United States)

An experiment was conducted in Chico, California, in 2013 and 2014 in order to quantify the accuracy and resolution of two-component vector wind fields resulting from the application of two motion estimation algorithms to image sequences from the REAL. A compact Doppler lidar was used to validate the remote wind estimates made by the REAL. The availability of good wind estimates at 100 m AGL in Chico is strongly correlated with the presence of coherent aerosol structures in the elastic backscatter data which is strongly linked to the diurnal cycle. In order to determine the maximum potential of the technique (in other words, the best it can do given the current state-of-the-art eye-safe elastic backscatter data), we restricted the analysis to the best 15 daytime periods containing abundant coherent aerosol features. From this data we computed 10-minute means for comparison with the Doppler lidar wind measurements and we computed spatial velocity power spectra from the velocity fields in order to estimate the filtering effect of the technique on small scale velocity perturbations. From this data subset, we found correlation coefficients with the Doppler lidar greater than 0.99. For spatial resolution, we assumed turbulent flow and a -5/3 power law dependence for velocity spectra. By comparing with the idealized spectra, we found the mean transfer function to equal 1 down to spatial scales of about 300 m. The mean transfer function rolls off towards smaller scales and is 0.88 at 205 m; 0.51 at 102 m; and 0.09 at 30 m.

9612-14, Session 4

Optical autocovariance wind Lidar: aircraft test-flight history and current plans

Sara C. Tucker, Ball Aerospace & Technologies Corp. (United States)

To address mission risk and cost limitations the US has faced in putting a much needed Doppler wind lidar into space, Ball Aerospace and Technologies Corp, with support from NASA's Earth Science Technology Office (ESTO), has developed the Optical Autocovariance Wind Lidar (OAWL), designed to measure winds from aerosol backscatter at the 355 nm wavelength, although the system has recently been modified to also operate at 532 nm. Preliminary proof of concept hardware efforts started at Ball back in 2004. From 2008 to 2012, under an ESTO-funded Instrument Incubator Program, Ball incorporated the Optical Autocovariance (OA) interferometer receiver into a prototype breadboard lidar system by adding a laser, telescope, and COTS-based data system for operation at the 355 nm wavelength. In 2011, the prototype system underwent ground-based validation testing, and three months later, after hardware and software modifications to ensure autonomous operation and aircraft safety, it was flown on the NASA WB-57 aircraft. The history of the 2011 test flights are reviewed, including efforts to get the system qualified for aircraft flights, modifications made during the flight test period, and the final flight data results. We also present lessons learned and plans for the new, robust, two-wavelength, aircraft system with flight demonstrations planned for Spring 2016.

9612-15, Session 5

1 micron wavelength single frequency pulsed fiber lasers with mJ pulse energy

Shibin Jiang, AdValue Photonics, Inc. (United States)

Single-frequency pulsed lasers are widely used for fiber optical sensing, nonlinear frequency conversion, and coherent lidar applications. 1 micron wavelength is still the most popular one because of the availability of related components and the sensitivity of the detectors. Coherent lidar application, especially airborne and space-borne coherent lidar, requires a high pulse energy. Free-space solid state laser can offer high pulse energy, but the long-term reliability is one of the major drawbacks. Fiber-based laser sources are much more reliable and more suitable for these applications, especially for their field deployment, but the pulse energy is limited to a few hundred microjoules.

In this paper we will present our recent progress of high pulse energy single frequency fiber laser at 1 micron wavelength using our proprietary Yb-doped fibers. A polarization maintaining Yb-doped fiber with a large mode field diameter was developed to effectively suppress stimulated Brillouin scattering (SBS). A singe frequency narrow linewidth laser is modulated and amplified via MOPA configuration. A pulse energy of greater than 1mJ was demonstrated, which represents several times increase in pulse energy. Amplified fiber lasers with pulse width from 5ns to 400ns will be presented.

9612-16, Session 5

Comparison of aerosol backscatter and wind field estimates from REAL and SAMPLE

Shane D. Mayor, Christopher F. Mauzey, Paul Arpin, Shea Arceo, California State Univ., Chico (United States); Scott Higdon, Thomas Chyba, Darrell Ramsey, Spectral Sensor Solutions, LLC (United States)

The Raman-shifted Eye-safe Aerosol Lidar (REAL) at California State University Chico provides high signal-to-noise ratio elastic backscatter to several kilometers range from individual laser pulses as a result of transmitting energetic pulses (120 - 170 mJ/pulse) at a low pulse repetition frequency (10 Hz). It employs analog direct detection. This results in impressive aerosol imagery that can be used with motion estimation algorithms to deduce vector wind fields. However, the REAL is large (housed in a shipping container) thereby limiting deployment opportunities. As an alternative, the Scanning Aerosol Micro Pulse Lidar Eyesafe (SAMPLE), available through Spectral Sensor Solutions LLC, is compact and operates at the same 1.5 micron wavelength as the REAL. It is a photo-counting aerosol lidar transmitting 350 microjoule pulses at 15 KHz. At the time of this writing, a side-by-side experiment involving both the REAL and the SAMPLE is planned to be conducted in northern California in March of 2015. Results from the experiment will be presented.

9612-17, Session 5

Performance characterization of a pressure-tuned wide-angle Michelson interferometric spectral filter for high spectral resolution Lidar

Shane T. Seaman, Anthony L. Cook, Salvatore J. Scola, Chris A. Hostetler, NASA Langley Research Ctr. (United States)

High Spectral Resolution Lidar (HSRL) is typically realized using an absorption filter to separate molecular returns from particulate returns. NASA Langley Research Center has designed and built a Pressure-Tuned Wide-Angle Michelson Interferometer (PTWAMI) as an alternate means to separate the two types of returns. Absorption filters only work within certain resonance/absorption frequencies and suffer from low photon efficiency. An interferometric spectral filter can be designed for any wavelength of interest and has greater photon efficiency. The principal challenge in successfully using an interferometer as a spectral filter for HSRL in flight is that variations in temperature and pressure cause the interferometer's optical path difference to change considerably. Therefore, a tuning mechanism must be used to actively accommodate for these changes in optical path difference. The pressure-tuning mechanism employed here relies on changing the pressure in an air-filled arm of the interferometer to change the arm's refractive index, and therefore optical path length. However, tuning using pressure will not adjust for tilt, warpage, or thermally induced wavefront error, so the structural, thermal, and optical behavior of the device must be well understood and optimized prior to flight. The PTWAMI has been characterized for particulate contrast ratio, thermal tuning rate, thermal stabilization time, wavefront error, and tilt. The results from these characterizations will be presented, and their correlation with a Structural Thermal Optical Performance (STOP) model will also be discussed.

9612-18, Session 5

Multi-wavelength high efficiency laser system for Lidar applications

Christina C. Willis, Charles Culpepper, Ralph L. Burnham, Fibertek, Inc. (United States)

Motivated by the growing need for more efficient, high output power laser transmitters, we demonstrate a multi-wavelength laser system for lidar-based applications. The first stage of the system is a 1064 nm MOPA system which employs two novel ceramic Nd:YAG slab amplifiers, the structure of which is designed to improve the amplifier's thermal performance and energy extraction. Each slab has three stages of progressive Nd doping concentration. This structure enabled an extraction efficiency of 24.6%, which constitutes a 19% increase in overall extraction efficiency over previous designs. A maximum energy of 34 mJ was produced at 500 Hz with a 10.8 ns pulse duration. The second stage of the system is a non-linear conversion system which consists of a KTP ring OPO with a BBO intra-cavity doubler pumped with 16 ns 1064 nm pulses. The OPO generates 1571 nm signal and 3300 nm idler wavelengths. The ring cavity is designed to circulate the 1571 nm signal and double it to 756 nm with intra-cavity BBO crystal. The output 786 nm pulses are then mixed with the 1064 nm pump pulses to generate 452 nm pulses. The optical conversion efficiency of this process was 17.1%, generating 3 mJ of 452 nm pulses of 7.8 ns duration, and an M2 of < 1.7 in both axes. Pump power was limited by intra-cavity damage thresholds, and in future experiments we anticipated >20% conversion efficiency and greater pump energy.

Conference 9613: Polarization Science and Remote Sensing VII

Tuesday - Wednesday 11–12 August 2015

Part of Proceedings of SPIE Vol. 9613 Polarization Science and Remote Sensing VII

9613-1, Session 1

Polarizer-free degree of polarization computational imaging from a single speckle image

Julien Fade, Institut de Physique de Rennes (France); Muriel Roche, Institut Fresnel (France); Mehdi Alouini, Institut de Physique de Rennes (France)

Imaging of the degree of polarization (DOP) of the light backscattered by a scene can reveal contrasts invisible in conventional reflectance images. Standard DOP imaging techniques involve multiple image acquisitions through several configurations of polarization analyzers: 4 images for standard Stokes imaging setup, while simplified imaging schemes, such as Orthogonal States Contrast (OSC) imaging, involve only 2 image acquisitions. We recently theoretically investigated the performances of an alternative DOP estimation technique, based on a single image acquisition of a sample under coherent illumination, without requiring any polarization analyzing device at the reception. Relying on a local analysis of the speckle intensity statistics in the image, this extremely simple technique has the potential to reach estimation performances compatible with applications to the expense of a high resolution detector. In this work, we first report the recent experimental validation of the applicability of this imaging technique on various samples, analyze its precision and test its robustness when illumination wavelength or imaging setup geometry are varied.

Then, we theoretically investigate the ability of this snapshot approach to discriminate samples with various depolarization degrees while sharing similar reflectance properties. Such detection tasks can indeed be of great interest for industrial applications. In that perspective, we quantitatively compare the detection performances of this approach with more standard polarization imaging strategies. We show on numerical simulations that the best compromise in terms of detection vs and false alarm rates requires the implementation of a generalized likelihood ratio test, which strongly outperforms much simpler moments-based detection tests.

9613-2, Session 1

Single shot diattenuation imaging by circular polarization orthogonality breaking

Noé Ortega-Quijano, Julien Fade, Institut de Physique de Rennes (France); Emmanuel Schaub, François Parnet, Univ. de Rennes 1 (France); Mehdi Alouini, Institut de Physique de Rennes (France)

Polarimetric sensing by orthogonality breaking is a recently proposed measurement principle which enables to perform a direct characterization of sample dichroism and/or depolarization in a single measurement, with a high dynamic range and acquisition speed. It relies on the use of a specific dual-frequency dual-polarization coherent source and on the measurement of a radio-frequency intensity beatnote induced by the sample dichroism/depolarization. In this work, we show that this approach enables to fully characterize the anisotropy parameters (magnitude and orientation angle) of a dichroic sample in a single measurement, by illuminating the sample with two orthogonal circularly-polarized modes with a slight frequency detuning. The source used in this work is based on a 40 mW commercial 488 nm monomode source that is introduced into a polarization splitting/combining Mach-Zehnder architecture. An acousto-optic modulator in one of the arms introduces a fixed frequency shift of 80MHz between the orthogonally-polarized circular states of polarization provided at the output of the source. This dual-frequency dual-polarization coherent source is then introduced into a laser scanning microscope, which enables to acquire a 256x256 pixels image in about 4 s only. The proposed method enables to determine diattenuation magnitude and orientation in a straightforward, fast and decoupled way. It is validated on several test samples and the potential of this technique to perform real-time dichroism imaging is explored on a synthetic imaging scenario. Moreover, this technique is easily adaptable to endoscopic systems due to its insensitivity to birefringence effects, hence representing an interesting approach for minimally-invasive tissue characterization.

9613-3, Session 1

Adaptive filters for bad pixel replacement in microgrid modulated polarimeters

Daniel A. LeMaster, Air Force Research Lab. (United States); Bradley M. Ratliff, Exelis Space Computer Corp. (United States)

Uncorrected or poorly corrected bad pixels reduce the effectiveness of polarimetric clutter suppression. The conventional approach to mitigating bad pixels for microgrid polarimetric imagers is the redundancy-based method. This method predates the literature of microgrid polarimetric image demodulation as a linear system. Furthermore, bad pixel replacement and Stokes image recovery are treated as separate steps. In this paper, we attempt to improve on the redundancy-based method by using adaptive filtering for joint bad pixel replacement and Stokes image demodulation.

9613-4, Session 1

Bandwidth and crosstalk considerations in modulated polarimeters with finite integration time

Israel J. Vaughn, Oscar G. Rodriguez-Herrera, College of Optical Sciences, The Univ. of Arizona (United States); Mohan Xu, The Univ. of Arizona (United States); J. Scott Tyo, College of Optical Sciences, The Univ. of Arizona (United States)

Recently we designed and built a portable imaging polarimeter for remote sensing applications. Polarimetric imaging operators are a class of linear systems operators in the Mueller matrix reconstruction space, resulting in a set of measurement channels. The nature of remote sensing requires channel crosstalk to be minimized for either general Mueller matrix reconstruction or task specific polarimetric remote sensing. We present a general framework which may be used for any modulated Mueller matrix reconstruction operator which minimizes channel crosstalk. We also discuss the constraints on these operators. We illustrate the framework with examples of specific spatio-temporally modulated system operators derived from our portable imaging polarimeter. Specifically channel cancellation allows increases in channel bandwidth. We also address the impact that systematic deviations from the ideal operators and i.i.d. noise have on Mueller matrix image reconstruction. We analyze the negative effects of the time-modulated polarization state generated and analyzed with dual-rotating retarder polarization state generators (PSG) and analyzers (PSA) on measurements obtained with Mueller matrix polarimeters with a finite integration time detector. We present strategies to decrease these effects by performing a reduced number of measurements at specific regions of the curve described over the Poincaré sphere by the instantaneous polarization in the PSG and PSA. The strategies presented are particularly suitable for polarimeters that require a relatively long integration time, such as systems with a sub-optimal detector or analyzing weakly scattering targets.

9613-5, Session 1

On demand polarimetry using a movable microgrid polarizer

Page King, Raytheon Co. (United States); Eric C. Fest, Raytheon Missile Systems (United States)

A movable pixelated filter array is proposed to provide low cost, on demand polarimetry and wavefront sensing. With this concept, an optical system can turn polarimetry on and off by using a shutter to move a microgrid polarizer array in and out of the optical path of the system. This allows an optical system to operate in two modes, a non-polarimetric mode in which sensor range is maintained, and a polarimetric mode in which it is reduced. In implementing this concept, adequate knowledge of the position of the filter in the optical path and calibration procedures become critical topics. This paper discusses simulated and hardware-tested results of this invention.

9613-6, Session 2

The twisted universe: cosmic polarimetry at the few parts-per-billion level *(Invited Paper)*

Brian G. Keating, Univ. of California, San Diego (United States)

The era of Cosmic Microwave Background B-mode polarization cosmology began in March 2014 with two landmark papers released within a week of each other. The BICEP2 telescope observed from the South Pole for three seasons (2010–2012) and released results showing an excess of B-modes in the degree angular scale range with >5 sigma significance. We find that this excess could not be explained by instrumental systematics and it was confirmed in cross-correlation with BICEP1 (at 100 and 150 GHz) and preliminary data from the Keck Array. The observed B-mode power spectrum was well-fit by a lensed-LCDM cosmological model with the addition of primordial tensor fluctuations. However, it is impossible to rule out foreground contamination and we are working alongside the Planck team to resolve this matter. I will discuss the BICEP2 experiment, observations, and data analysis. One week before the BICEP2 announcement, the POLARBEAR telescope (which observed from the Atacama Desert, Chile for one season 2012-2013) announced the first evidence for B-modes at sub-degree scales caused by gravitational lensing of the CMB's E-modes by large scale structure at low-redshift. The combination of the BICEP2 and POLARBEAR results paves the way towards precision tests of inflation, foreground contamination as well as probes of other aspects of fundamental physics including measuring the number and masses of cosmological neutrinos.

9613-7, Session 2

Complete intrinsic coincident polarimetry using stacked organic photovoltaics

Subharup Gupta Roy, Omar M. Awartani, Pratik Sen, Brendan T. O'Connor, Michael W. Kudenov, North Carolina State Univ. (United States)

Measuring 2-D Stokes vector, to determine the polarization state of light, finds application in multiple areas, including the characterization of aerosol size distributions, military purposes (e,g, target sighting), quality control for evaluating the distribution of stress birefringence, resolving data channels in telecommunications, and for evaluating biological tissues in medical imaging. Conventional methods, such as channeled (CH) and division of focal plane (DoF) polarimeters, usually limit spatial resolution, while others, like division of aperture (DoA) or division of amplitude (DoA) polarimeters, have higher complexity and less compactness. To solve these issues, we developed a system that uses organic photovoltaics (OPVs) as photodetectors. The active area of the devices have strain aligned polymer chains in a periodic arrangement, which enables the device to preferentially absorb certain polarized states of incident light, depending on the orientation of the polymer chains. Taking advantage of the cells' transparency and ease of processing compared to inorganic materials, several devices can be stacked along the optical axis. We use four stacked OPVs, where each device can measure one of the four Stokes parameters simultaneously, thereby ensuring high spatial and temporal resolution with inherent spatial registration. In this paper, the fabrication of the OPVs and the design and calibration technique is documented along with experimental data, supporting the hypothesis.

9613-8, Session 2

Integrated computational imaging system for enhanced polarimetric measurements

Shahid A. Haider, Farnoud Kazemzadeh, Alexander Wong, David A. Clausi, Univ. of Waterloo (Canada)

Polarimetry is a common technique used in chemistry for solution characterization and analysis, giving insight into the molecular structure of a solution measured through the rotation of linearly polarized light. This rotation is characterized by the Boit-Savart's law. Without large optical path lengths, or high concentrations of solution, these optical rotations are typically very small, requiring elaborate and costly apparatuses. To ensure that the rotation measurements are accurate, these devices usually perform complex optical procedures or time-averaged point measurements to ensure that any intensity variation seen is a product of optical rotation and not from inherent noise sources in the system, such as sensor or shot noise. Time averaging is a lengthy process and rarely utilizes all of the information available on the sensor. To this end, we have developed a novel integrated, miniature, computational imaging system that enhances polarimetric measurements that takes advantage of the full spot size observed on an array detector. This computational imaging system is capable of using a single acquisition at unity gain to enhance the polarimetric measurements using a probabilistic framework, which accounts for inherent noise and optical characteristics in the acquisition process, to take advantage of spatial intensity relations. This approach is faster than time-averaging methods and can better account for any measurement uncertainties. In preliminary experiments, this system has produced comparably consistent measurements across multiple trials with the same chemical solution than time averaging techniques.

9613-9, Session 3

Snapshot retinal imaging Mueller matrix polarimeter

Yifan Wang, Michael Kudenov, North Carolina State Univ. (United States); Amir Kashani, Keck School of Medicine (United States); Jim Schwiegerling, College of Optical Sciences, The Univ. of Arizona (United States)

Glaucoma is the second leading cause of visual impairment in the world. An especially significant step for successful glaucoma treatment is early diagnosis. It has been vastly known that, through scanning laser polarimetry (SLP) and scanning laser Mueller matrix (MM) polarimetry techniques, the pathologic changes on retinal nerve fiber layer (RNFL) could be detected before complete atrophy, leading to earlier diagnosis of glaucoma. However, these techniques currently have limitations such as limited sensing region on retina and motion artifacts due to the temporal scanning nature.
In this paper, we theoretically and experimentally present a snapshot Mueller Matrix Polarimeter (SMMP) fundus camera, which is able to record polarization-altering characteristics of relatively large areas on retina with a single snapshot. It is made by incorporating broad-band polarization gratings into fundus camera design as generator and analyzer of the polarization fringes. A complete Mueller Matrix data set with high temporal resolution is obtained by analyzing the polarization patterns projected onto the image plane. Thus, the measurement errors due to diattenuation and depolarization of the RNFL are minimized. We believe that the SMMP holds

great potential for being applied as a practical instrument for screening glaucoma patients in the future.

9613-10, Session 3

A polarization system for persistent chemical detection

Julia Craven-Jones, Leah Appelhans, Todd Embree, Patrick Finnegan, Sandia National Labs. (United States); Dennis Goldstein, Polaris Sensor Technologies, Inc. (United States); Charles LaCasse, Ting S. Luk, Sandia National Labs. (United States); Adoum Mahamat, College of Optical Sciences, The Univ. of Arizona (United States); Lee Massey, Anthony Tanbakuchi, Cody Washburn, Steven Vigil, Sandia National Labs. (United States)

We report on the development of a prototype polarization tag based system for detecting chemical vapors. The system primarily consists of two components, a chemically sensitive tag that experiences a change in its optical polarization properties when exposed to a specific chemical of interest, and an optical polarimeter that is used to measure the polarization properties of the tags. Although the system concept could be extended to other chemicals, for the initial system prototype presented here the tags were developed to be sensitive to hydrogen fluoride (HF) vapors. HF is used in many industrial processes but is highly toxic and thus monitoring for its presence and concentration is often of interest for personnel and environmental safety. The tags are periodic multilayer structures that are produced using standard photolithographic processes. The polarimetric imager has been designed to measure the degree of linear polarization reflected from the tags in the short wave infrared. By monitoring the change in the reflected polarization signature from the tags, the polarimeter can be used to determine if the tag was exposed to HF gas. In this paper, a review of the system development effort and preliminary test results are presented and discussed, as well as our plan for future work.

9613-11, Session 3

Full-field imaging for spectroscopic stokes parameters in all directions and its application to flaw detection

Hiroshi Hasegawa, Yukitoshi Otani, Utsunomiya Univ. (Japan)

This paper describes a spectroscopic imaging Stokes polarimeter by dual rotation retarder and analyzer on a six-axis robot arm. It is succeeded to calibrate of wavelength dependence of its retarder. To measure in all field of entire circumference, the Stokes polarimeter is attached on the robot arm. It is succeeded to measure the state of polarization of a sample from reflected light, scattered light and transmitted light from any angle in all directions. It is also applied to detect flaw detections of lenses.

9613-12, Session 4

Innovative static spectropolarimeter concept for wide spectral ranges

Martin Pertenais, Observatoire de Paris à Meudon (France) and Univ. de Toulouse (France); Coralie Neiner, Observatoire de Paris à Meudon (France); Laurent P. Parès, Observatoire Midi-Pyrénées (France) and Univ. de Toulouse (France); Pascal M. Petit, Univ. de Toulouse (France) and Institut de Recherche en Astrophysique et Planétologie (France)

Developing an efficient and robust polarimeter for wide spectral ranges and space applications is a main issue in many projects. As part of the UVMag consortium created to develop UV facilities in space (e.g. the Arago mission proposed to ESA), we are studying an innovative concept of polarimeter that is robust, simple, and efficient on a wide spectral range. The idea, based on the article by Sparks et al. (2012), is to use polarization scramblers to create a spatial modulation of the polarization. Along the height of the wedges of the scramblers, the thickness of the birefringent material crossed by the light, and thus the retardance, vary continuously. This variation creates an intensity modulation of the light related to the entrance polarization state. Analyzing this modulation with a linear polarizer, and dispersing the light spectrally in the orthogonal spatial direction, enables the measurement of the full Stokes vector over the entire spectrum. This determination is made with a single-shot measurement and without any moving parts in the system.

During this talk, I will develop the theory of this concept and present the first laboratory results of our prototype. In the future, we will test and validate this concept in space environment and in the FUV range.

9613-13, Session 4

Snapshot Mueller-matrix spectropolarimeter using spectral and spatial carriers

Kazuhiko Oka, Yujin Haga, Hiroshi Michida, Hokkaido Univ. (Japan)

We report on a novel spectroscopic Mueller-matrix polarimeter based on channeled spectropolarimetry. The channeled spectropolarimetry is a method for measuring polarimetric parameters using a cosinusoidally-modulated spectrum. Although a channeled Mueller-matrix spectropolarimeter using only spectral carriers has been proposed, it requires a spectrometer with a high spectral resolution so that sixteen Mueller matrix elements can be discriminated only in the one-dimensional Fourier domain. In this work, to relax the severe requirement, we incorporate spatial as well as spectral carriers in the channeled Mueller-matrix spectropolarimeter. In the developed system, light from a Xe lamp first passes through a spectral polarization state modulator, consisting of a polarizer and two high-order retarders, and is then transmitted by a sample under measurement. The light emerging from the sample is fed into a polarization state analyzer using spatial carriers, including two Savart plates, and impinges upon a spectrometer with two-dimensional CCD. The obtained two-dimensional spectrum is cosinusoidally modulated along both wavenumber- and space-axes. The two-dimensional Fourier analysis of the spectrum allows us to demodulate the wavenumber-resolved Mueller matrix of the sample. The spectropolarimeter uses no mechanical or active elements for the polarization modulation and the snapshot measurement of sixteen Mueller-matrix elements can be achieved. In addition, a spectrometer with much lower spectral resolution can be used compared to the previous method using only spectral carriers. The feasibility of the proposed implementation was experimentally demonstrated in the spectral range between 500 and 750 nm.

9613-14, Session 4

High precision stokes polarimeter for scattered light by intensity detection with high dynamic range

Yukitoshi Otani, Shuhei Shibata, Tomohiro Kiire, Yoshio Hayasaki, Toyohiko Yatagai, Utsunomiya Univ. (Japan)

This paper describes a high precision Stokes polarimeter for scattered light by a detector of high dynamic range with six ranges of neutral density (ND) filters which have different absorption ratio. A photon counting system is used to capture the intensities. Its dynamic range is achieved up to the tenth power of ten by combination of NDs. The measuring algorism of Stokes parameters are proposed a dual rotating retarder and analyzer

which can be calibrated polarization errors such as retardance error and diattenuation error. The accuracy of Stokes parameters was achieved 0.003 in transmission type. The Stokes parameters of scattered light of glass material was measured from -20°to 20° in detection angle.

9613-15, Session 4

A multi-domain full-Stokes polarization modulator that is efficient for 300-2500nm spectropolarimetry

Frans Snik, Gerard van Harten, Leiden Observatory (Netherlands); Andrey Alenin, J. Scott Tyo, College of Optical Sciences, The Univ. of Arizona (United States)

We present the design and prototyping results for an ultra-wideband rotating polarization modulator that consists of a stack of quartz plates. The plate thicknesses and orientations were optimized such that after rotation of the modulator to 6 different angles before a polarization analyzer, the full Stokes vector can be optimally determined at all wavelengths from 300 to 2500 nm. Additional optimization parameters include minimal variation of the retardance with incidence angle and temperature, and the suppression of polarized spectral fringes for a spectral resolution of 10,000. The prototype modulator's design was re-optimized after the production and measurement of each individual quartz plate. We present the performance of the as-built prototype.

To eliminate aliasing with inherent temporal variations of the source, the modulator can be used together with a polarizing beam-splitter ("dual-beam" approach). Because of the large sinusoidal spectral variations of the polarization modulation, this modulator can also be considered a "spectral modulator for channeled spectropolarimetry". Therefore, at each modulation state, spectrally resolved polarization information can also be extracted directly, although at limited spectral resolution. We use this modulator as an example of a "multi-domain polarization modulator", and outline a general approach for optimally storing polarization information in all available measurement dimensions (temporal, spatial, spectral), and rendering the overall polarization measurement independent from systematic effects in any of these dimensions.

9613-16, Session 5

Polarization aberration in astronomical telescopes

Russell A. Chipman, James B. Breckinridge, Wai Sze T. Lam, College of Optical Sciences, The Univ. of Arizona (United States)

The PSF for astronomical telescopes and instruments depends not only on geometric aberrations and scalar wave diffraction, but also on those wavefront errors introduced by the physical optics and the polarization properties of reflecting and transmitting surfaces within the optical system. These vector wave aberrations, called polarization aberrations, result from two sources the mirror coatings necessary to make the highly reflecting mirror surfaces, and the angles of incidence. The analytical tools to calculate the PSF image are described. The point spread function consists of four separate components, which include two faint components with a spatial extent about twice the size of the diffraction limited image. An example telescope system is analyzed to help understand how astronomical image data is affected by instrumental polarization.

9613-17, Session 5

Polarization modulators based on liquid crystal variable retarders for the solar orbiter mission

Alberto Alvarez-Herrero, Pilar García Parejo, Hugo Laguna, Javier Villanueva, Javier Barandiarán, Laurent Bastide, Manuel Reina, Isabel Vera, Mayte Royo, INTA Instituto Nacional de Técnica Aeroespacial (Spain)

A polarization modulator based on Liquid Crystal Variable Retarders (LCVRs) will be used in the Polarimetric and Helioseismic Imager (PHI) for the Solar Orbiter mission to measure the complete Stokes vector of the incoming light. PHI is one of the six remote sensing instruments onboard of this space mission led by the European Space Agency (ESA) with strong NASA participation. It is an imaging spectro-polarimeter that will acquire high resolution solar magnetograms. Also the LCVRs will be used in the polarization modulator of the METIS instrument (Multi Element Telescope for Imaging and Spectroscopy). METIS is a solar coronagraph that will analyze the linear polarization for observations of the visible-light K-corona.

The polarization modulators are described in this work including the optical, mechanical, thermal and electrical aspects. Both modulators will consist of two identical LCVRs with a relative azimuth orientation of 45º for PHI and parallel for the METIS modulator. In the first case, the configuration allows the analysis of the full Stokes vector with maximum polarimetric efficiencies. In the second setup, wide acceptance angles (≤±7º) are obtained.

In this work the results obtained from the full representative prototypes after the verification and environmental test campaigns are presented. The main performances were measured and analyzed including polarimetric efficiencies, wavefront error transmission, transmittance and response times. This valuable information has allowed to finish the detailed design of these devices and to proceed to the manufacturing of the Qualification Model (QM) and Flight Models (FM).

9613-18, Session 5

The Polaris-M ray tracing program

Russell A. Chipman, Wai Sze T. Lam, College of Optical Sciences, The Univ. of Arizona (United States)

An optical design program developed at the University of Arizona incorporates many advanced polarization analysis features. At the core of the program is a three-dimensional polarization ray tracing structure used to characterize polarization effects occurring at interfaces and upon propagation through anisotropic materials. Reflection and refraction at uniaxial, biaxial, and optically active interfaces are handled rigorously, as our anisotropic grating structures. By analyzing multiple polarized wavefront components individually, one can study the complicated effects of multiple anisotropic optical elements at the image. A ray tree structure keeps track of ray doubling at anisotropic interfaces and ray multiplication at gratings. Wavefronts can be expanded into polarization aberration terms. Polarized diffraction image formation and polarization dependent optical transfer functions are included.

9613-19, Session 6

The geostationary operational environmental satellite R-series advanced baseline imager: polarization sensitivity and potential impacts

Aaron J. Pearlman, ERT, Inc. (United States) and NOAA National Environmental Satellite, Data, and Information Service (United States); Changyong Cao, NOAA National Environmental Satellite, Data, and Information Service

(United States); Xiangqian Wu, National Oceanic and Atmospheric Administration (United States)

The Advanced Baseline Imager (ABI) will fly aboard the Geostationary Operational Environmental Satellite R-Series (GOES-R). Contrary to National Oceanic and Atmospheric Administration's current imagers for operational weather forecasting, this newest version, which is planned to launch in 2016, will have six reflective solar bands - five more than currently available. These bands will be used for applications such as aerosol retrievals, which are influenced by polarization effects.

Characterizing these effects is part of the extensive pre-launch testing that has been done to ensure the high quality of Level 1b data. The vendor characterized the polarization sensitivity in the 0.47 μm and 0.64 μm channels by recording the ABI counts while illuminated with an integrating sphere and through a linear polarizer set to different angles. The polarizer was characterized by placing an additional polarizer in front of the ABI and repeating the measurements.

We analyzed the results using a formulation that accounts for the non-ideal properties of the polarizing filter and assessed the measurement uncertainties. We also compared the measurement results with outputs from optical models produced by the instrument vendor. To estimate the radiometric performance impacts from the instrument polarization sensitivity, we simulated polarized scenes using a radiative transfer code and accounted for the instrument polarization sensitivity over its field of regard. The impacts varied with channel wavelength and aerosol model type. This work enhances our ability to diagnose and resolve polarization-related anomalies on-orbit and reduce calibration uncertainty for improved system performance.

The manuscript contents are solely the opinions of the authors and do not constitute a statement of policy, decision, or position on behalf of NOAA or the U.S. government.

9613-20, Session 6

Why diffractive retarders are not in common use

Russell A. Chipman, College of Optical Sciences, The Univ. of Arizona (United States)

Diffractive retarders fabricated from gratings in isotropic materials are analyzed by rigorous coupled wave analysis. The efficiency and dispersion of these gratings is compared to the conventional materials used in the majority of retarders.

9613-21, Session 7

Channeled partial Mueller matrix polarimetry

Andrey S. Alenin, J. Scott Tyo, College of Optical Sciences, The Univ. of Arizona (United States)

In prior work, we introduced methods to treat channeled systems in a way that is similar to Data Reduction Method (DRM), by focusing attention on the Fourier content of the measurement conditions. Introduction of Q enabled us to more readily extract the performance of the system and thereby optimize it to obtain reconstruction with the least noise. The analysis tools developed for that exercise can be expanded to be applicable to partial Mueller Matrix Polarimeters (pMMPs), which were a topic of prior discussion as well. In this treatment, we combine the principles involved in both of those research trajectories and identify a set of channeled pMMP families. As a result, the measurement structure of such systems is completely known and the design of a channeled pMMP intended for any given task becomes a search over a finite set of possibilities.

9613-22, Session 7

Ray tracing based path-length calculations for polarized light tomographic imaging

Rakesh Manjappa, Rajan Kanhirodan, Indian Institute of Science (India)

The amount of light absorbed inside a biological tissue gives away a lot of hidden information about the composition and dynamics inside. For example, the diffuse optical tomography (DOT) depends on fluence distribution inside the tissue to arrive at the absorption coefficient map. The study of polarized light transport through a tissue material has many biomedical applications. It provides a powerful tool to study the interaction of light with a turbid media. The degree of polarization (DOP) provides a pointer to the disease state of a tissue.

A ray tracing based path length calculation is investigated for polarized light transport in a pixel space. Tomographic imaging using polarized light transport is promising for applications in optical projection tomography of small animal imaging and samples with low scattering. Polarized light transport through a medium can have complex effects due to interactions such as optical rotation of linearly polarized light, birefringence, interior refraction etc... Here we investigate the effects of refraction of polarized light in a non-scattering medium. This step is used to obtain the initial absorption estimate. This can be used as prior in Monte Carlo methods to assist in faster convergence of the final estimate. The principle of polarization by refraction uses the fact that at certain angles of incidence (Brewster's angle) only the perpendicular component is reflected.

The transmission medium consists of regions of homogeneous refractive index (RI) values with an embedded inhomogeneity having a RI different from the homogeneous background. The proposed method takes care of refractive index mismatches at the interface and corrects for the interior ray bending. Snell's law is used to arrive at the direction after interior refraction. The reflectance for p-polarized (parallel) and s-polarized (perpendicular) are different and hence there is a difference in the intensities that reach the detector end.

The algorithm computes the length of the ray in each pixel along the refracted path and this is used to build the weight matrix. This weight matrix with corrected ray path length and the resultant intensity reaching the detector for each ray is used in the algebraic reconstruction method. The proposed method is tested with numerical phantoms for various noise levels. Refraction at interior inhomogeneities results in inaccurate reconstruction while using filtered back-projection algorithm.

It is important to note that when the refractive index mismatch is less (i.e less than 0.2 RI Units) there is no significant difference between reflection coefficients of the two polarization states of light, and the value is same as that of unpolarized light. As the refractive index mismatch between the region and inhomogeneity increases the difference between reflection coefficients Rs and Rp increases and is most prominent when the mismatch is highest.

Air bubble (with RI=1.0) inside a gel dosimeter with the surrounding medium presents such a scenario. The surrounding gel medium typically has a high refractive index of 1.35 to 1.5 depending on the material used. Similar is the case of air pockets inside tissue. Micro-CT using X-ray, has been used to image the contrast between regions of air and tissue. Here we propose to use polarization based optical techniques to quantify the contrast. Preliminary analysis and results show that polarization based imaging is promising.

The refraction errors due to regions of different refractive indices are discussed, the difference in intensities with polarization is considered. The improvements in reconstruction using corrections is presented. This is achieved by tracking the path of the ray as well as the intensity of the ray as it traverses through the medium.

9613-23, Session 7

Bandwidth and information in the design and analysis of polarimeters *(Invited Paper)*

J. Scott Tyo, College of Optical Sciences, The Univ. of Arizona (United States) and Univ. of New South Wales, Canberra (Australia)

Over the past decade, the Advanced Sensing Laboratory at the College of Optical Sciences has been working with several collaborating groups on improving the understanding of information content in polarimeter measurements. What began as an effort to understand noise and error in the calibration of polarimeters evolved into an understanding of how the various bandwidths available in an instrument (spatial, temporal, spectral, angle of incidence) map on to the corresponding domains of the polarization objects that are being measured. In this presentation, I will review some of key historical results from our group and from others, and show how they are all fundamentally related in considering the unique information content of the individual polarimeter measurements. Applications of these methods in microgrid polarimeters, partial Mueller polarimeters, coherence sensors, and advanced polarimeter modulation schemes will all be considered. Much of the talk will be a historical review, but special emphasis will be made on the aspects that inform current research projects that are being considered in depth in other talks at the meeting.

9613-24, Session 8

The visible-to-SWIR spectrum of skylight polarization

Laura M. Dahl, Joseph A. Shaw, Montana State Univ. (United States)

For a clear-sky atmosphere, a successive orders of scattering (SOS) radiative transfer model can estimate the degree of polarization (DoP) in the sky accurately. We previously published measurements and simulations illustrating the complex interaction of atmospheric molecular and aerosol properties with surface reflectance in determining the spectrum of skylight polarization from the visible to 1 ?m wavelength in the near infrared. Those results showed that skylight polarization can trend upward or downward, or even have unusual spectral discontinuities that arise because of sharp features in the underlying surface reflectance. The specific spectrum that is observed in any given case depends strongly on atmospheric and surface properties that vary with wavelength. In the previous study, the SOS model was fed with actual measurements of highly variable aerosol and surface properties from locations around the world. Results, however, were limited to wavelengths below 1 ?m because of the lack of appropriate satellite measurements of surface reflectance at longer wavelengths. We now report measurement-driven simulations of skylight polarization, extending from 400 nm to 2500 nm in the short-wave infrared (SWIR). Rather than relying on satellite information, the surface reflectance was measured with a ground-based spectrometer. The basic optical physics of the skylight polarization process and example results of the skylight polarization spectra for the vis-NIR-SWIR spectral region (400-2500 nm) will be presented.

9613-25, Session 8

Light scattering by roughed spheroids: a database of dust aerosols for POLDER/PARASOL 490, 670 and 865nm channels

Jianping Liu, Ping Yang, Texas A&M Univ. (United States); Ralph Kahn, NASA Goddard Space Flight Ctr. (United States)

A database is developed containing the comprehensive single-scattering properties (namely, the 4x4 phase matrix, extinction cross section, and single-scattering albedo) of dust aerosols for application to remote sensing based on POLDER/PARASOL 490, 670 and 865 nm channels. A roughed spheroid model is developed for the single-scattering computation with a combination of the invariant imbedding T-matrix method (IITM) and the improved geometric optics method (IGOM). Properties such as the extinction efficiency, single-scattering albedo, asymmetry factor and phase matrix are provided for a set of discretized parameters including the size parameter, the aspect ratio, the real and imaginary parts of the refractive index and the degree of roughness. Furthermore, the database is applied to the retrieval of the microphysical properties (specifically, the aspect ratio and degree of surface roughness) of dust aerosols through the comparison between the simulated polarized reflectance and POLDER/PARASOL satellite observations.

9613-26, Session 8

Morphological operators for enhanced polarimetric imaging target detection

Joao M. Romano, U.S. Army Armament Research, Development and Engineering Ctr. (United States); Dalton S. Rosario, U.S. Army Research Lab. (United States)

We introduce an algorithm of morphological filters and propose its use to the information content of classic polarization metrics for commercial or military applications requiring passive longwave infrared polarimetric remote sensing and real-time anomaly detection. The approach has shown to significantly augment the daytime and nighttime detection of weak-signal manmade objects immersed in a predominant natural background scene (foliage, terrain). The approach features a tailored sequence of signal-enhancing filters, consisting of core morphological operators (dilation, erosion) and higher level morphological operations (e.g., spatial gradient, opening, closing) to achieve a desired overarching goal. Qualitatively, the goal is to effectively squeeze the variance of pixel values representing the natural clutter background, while simultaneously spreading the pixel variance within the manmade object class and separating the pixel mean averages between the two object classes (natural and manmade). Using represented data from a large database known as SPICE, where continuous data acquisition covered a 72-h time period, the results show that the approach was able to automatically and persistently detect with a high confidence level the presence of three mobile military howitzer surrogates (targets) in natural clutter, posed at three distinct aspect angles at a range of 557 m. The approach detected the targets as scene anomalies, yielding a negligible false alarm rate. The targets' heating components were mostly turned off during data acquisition, with a few exceptions. The approach yielded performance invariance toward four major sources of signature variation: diurnal cycle, mild atmospheric changes, geometry of illumination, and target's thermal operating condition.

9613-27, Session 9

Accurate spectrally modulating polarimeters for atmospheric aerosol characterization

Jeroen H. H. Rietjens, Martijn Smit, SRON Netherlands Institute for Space Research (Netherlands); Gerard van Harten, Leiden Observatory (Netherlands); Antonio Di Noia, Otto P. Hasekamp, SRON Netherlands Institute for Space Research (Netherlands); Jos de Boer, Leiden Observatory (Netherlands); Hester Volten, Rijksinstituut voor Volksgezondheid en Milieu (Netherlands); Frans Snik, Christoph U. Keller, Leiden Observatory (Netherlands)

Multi-angle spectro-polarimetry holds great potential as a remote sensing technique to derive information about aerosol suspended in the Earth's atmosphere. A consortium of Dutch research institutes has developed a spectro-polarimeter that is based on spectral polarization modulation: by encoding the polarization state of scattered sunlight in a sinusoidal

modulation in the intensity spectrum, the spectral flux and state of polarization are measured simultaneously in a single measurement of a target scene. As a consequence, this passive method enables highly accurate and reliable spectro-polarimetry.

The technique has been employed in two instrument realizations. The SPEX-prototype is developed for space-based observations and is a multi-angle viewing instrument with nine fixed viewing apertures. This instrument is currently upgraded to perform aerosol characterization campaigns on-board an ER-2 research aircraft together with NASA's Research Scanning Polarimeter. Another realization, groundSPEX, has a single scanning viewing aperture and was developed specifically for air-quality observations made from the ground.

We will present lab calibration results using a recently developed polarization calibration stimulus and compare the polarimeteric accuracy of both instruments, which are better than 0.005.

Also, we will show results of ground-based multi-angle spectro-polarimetric diffuse sky measurements with both SPEX instruments at the Cabauw Experimental Site for Atmospheric Research (CESAR). Retrievals of aerosol characterization parameters (e.g. aerosol optical thickness, refractive index, and effective radii) will be intercompared and validated against products of the co-located AERONET station. The results indicate that the SPEX measurement concept has the power to deliver high quality aerosol parameters.

9613-28, Session 9

Applying a microfacet model to polarized light scattering measurements of the Earth's surface

Meredith K. Kupinski, Christine L. Bradley, College of Optical Sciences, The Univ. of Arizona (United States); David Diner, Feng Xu, Jet Propulsion Lab. (United States); Russell Chipman, College of Optical Sciences, The Univ. of Arizona (United States)

Currently, urban air quality monitoring systems rely exclusively on ground-based sun photometers, which do not provide adequate spatial or optical sampling to constrain the inverse problem of global aerosol estimation. A downward-looking polarimeter collects light from both the atmosphere and the Earth's surface and can provide information for global aerosol estimation. Currently, models of atmospheric scattering are more advanced than models of surface reflectance because the polarized light scattering from the Earth's surface is globally diverse and all analysis to date has been empirical. To extract the optical and microphysical properties of aerosols over urban areas, it is essential to have more accurate models for polarized surface reflectance coupled to atmospheric radiative transfer.

In this work, three years of observations from JPL's Ground-based Multiangle SpectroPolarimetric Imager (GroundMSPI) are used to evaluate a surface polarized bidirectional reflectance distribution function (p-BRDF) model. GroundMSPI is an eight-band spectropolarimetric camera mounted on a rotating gimbal to acquire pushbroom imagery of outdoor landscapes. The camera uses a photoelastic-modulator-based polarimetric imaging technique to measure linear Stokes parameters in three wavebands (470, 660, and 865 nm) with a 0.005 uncertainty in degree of linear polarization. Data collected during the course of the day provided a range of illumination geometries that facilitated evaluation of the p-BRDF model, which is comprised of a volumetric reflection term plus a specular reflection term generated by a randomly oriented array of Fresnel-reflecting microfacets. We report on the appropriateness of this p-BRDF model for manmade materials as compared to natural materials.

9613-29, Session 9

Spectral invariance hypothesis study of polarized reflectance with ground-based multiangle spectropolarimetric imager (GroundMSPI)

Christine L. Bradley, Meredith Kupinski, College of Optical Sciences, The Univ. of Arizona (United States); David J. Diner, Jet Propulsion Lab. (United States); Russell A. Chipman, College of Optical Sciences, The Univ. of Arizona (United States)

Many models used to represent the boundary condition for the separation of atmospheric scattering from the surface reflectance in polarized remote sensing measurements assume that the polarized surface reflectance is spectrally neutral. Though this is a common assumption in polarized bidirectional reflectance distribution (pBRDF) models, little data has been published to support this hypothesis. The Spectral Invariance Hypothesis states that the magnitude and shape of the pBRDF is equal for all wavelengths. In order to test this hypothesis, JPL's ground-based Multiangle SpectroPolarimetric Imager (GroundMSPI) is used to measure polarization information of different outdoor surface types. GroundMSPI measures the linear polarization Stokes parameters (I, Q, U), at three wavebands, 470 nm, 660 nm, and 865 nm. The camera is mounted on a two-axis gimbaled mount to accurately select the view azimuth and elevation directions. We set the instrument up on clear sky days to acquire daylong scans of scenes that contain various surface types such as grass, dirt, cement, and asphalt with a Spectralon panel in the camera field of view. Over the course of a day, the sun changes its position in the sky to provide a large range of scattering angles for this study. The pBRDF is calculated for the three wavelengths and the spectral correlation is reported. This work investigates the validity of the spectral invariance assumption for different types of materials in outdoor scenes.

9613-30, Session 9

Optimal contrast enhancement in long distance snapshot polarimetric imaging through fog

Swapnesh Panigrahi, Univ. de Rennes 1 (France); Julien Fade, Mehdi Alouini, Institut de Physique de Rennes (France); Hema Ramachandran, Raman Research Institute (India)

We investigate optimal contrast enhancement of a polarized light beacon through fog over long distances, for navigation assistance and transportation safety in low visibility conditions. To this aim, we have set up a long distance imaging experiment spanning over a kilometer to obtain polarimetric images of a scene containing an incoherent linearly polarized light beacon embedded in fog. Using a Wollaston prism-based snapshot polarimetric camera, we obtain two simultaneous images of a scene in orthogonal polarizations. A suitable combination of the two acquired images is sought such that the contrast of the polarized source is maximized in the resulting image. Using a correlated Gaussian model to describe noise fluctuations in the polarimetric images, we theoretically exhibit the optimal form of such contrast-maximizing representation, and show that it simply consists of a linear combination of the two acquired images with appropriate weighting. This optimal representation differs in general from standard polarimetric image representations used in the literature and strongly depends on atmospheric/visibility conditions. The implementation of such adaptive optimal representation simply requires local estimation of the noise correlation coefficient and is therefore highly compatible with real-time constraints, even when the number and location of polarized sources in the image are unknown. Using such an information theoretical approach, we also compute the optimal gain in contrast that can be obtained by using a polarization sensitive camera in various atmospheric conditions. The optimality of this representation and the theoretical gain expected are

experimentally confirmed on various data acquisitions obtained in different atmospheric conditions.

9613-31, Session 9

Characterization of sun and sky glint from wind ruffled sea surfaces for improved estimation of polarized remote sensing reflectance

Robert Foster, Amir Ibrahim, Alex Gilerson, Ahmed El-Habashi, Carlos Carrizo, Sam Ahmed, The City College of New York (United States)

During two cruises in 2014, the polarized radiance of the ocean and the sky were continuously acquired using a HyperSAS-POL system. The system consists of 6 hyperspectral radiometric sensors, three of which (one unpolarized and two polarized) look at the water and similarly three at the sky. The system autonomously tracks the Sun position and the heading of the research vessel to which it is attached in order to maintain a fixed relative azimuth angle with respect to the Sun (i.e. 90°) and therefore avoid the specular reflection of the sunlight. For the duration of both cruises, (NASA Ship Aircraft Bio-Optical Research (SABOR), and NOAA VIIRS Validation/Calibration), in-situ inherent optical properties (IOPs) were continuously acquired using a set of instrument packages modified for underway measurement, and hyperspectral radiometric measurements were taken manually at all stations. During SABOR, an underwater polarimeter and a full Stokes polarization camera were deployed when conditions permitted. All measurements, above and below the sea surface, were combined and compared in an effort to first develop a glint (sky + Sun) correction scheme for the upwelling polarized signal from the ocean, and compare this signal with one simulated by a vector radiative transfer code using the measured IOPs as input. Further, we examine the relationship recently developed by us between the degree of linear polarization (DoLP) and the optical properties of ocean waters, specifically the ratio of the attenuation to absorption coefficients. Relationships between the DoLP and microphysics of particulates are also analyzed.

9613-32, Session 10

Material identification using polarimetric hyperspectral imagery

Jacob A. Martin, Kevin C. Gross, Air Force Institute of Technology (United States) and Oak Ridge Institute for Science and Education (United States)

Polarimetric hyperspectral imaging (P-HSI) combines two common remote sensing modalities. This work leverages the combination of these techniques to improve material classification. Classifying and identifying materials requires parameters which are invariant to changing viewing conditions, most often a materialÃ¸Ts reflectivity or emissivity is used. Measuring these most often requires assumptions be made about the material and atmospheric conditions. Utilizing both polarimetric and hyperspectral imaging, we can remotely estimate the index of refraction of a material, while simultaneously solving for a handful of parameters describing the atmosphere. In general, this is an underdetermined problem because both the real and imaginary components of index of refraction are unknown at every spectral point. By modeling the spectral variation of the index of refraction using a few parameters, however, the problem can be made overdetermined. A number of different functions can be used to describe this spectral variation, and some are discussed here. Reducing the number of spectral parameters to fit allows us to add parameters which estimate atmospheric downwelling radiance and transmittance. Additionally, the object temperature is added as a fit parameter. The set of these parameters that best replicate the measured data is then found using a bounded Nelder-Mead simplex search algorithm. Other search algorithms are also examined and discussed. Results show that this technique has promise, but also some limitations, which are the subject of ongoing work.

9613-33, Session 10

Polarization-based complex index of refraction estimation with volumetric scattering consideration

Hanyu Zhan, David G. Voelz, Xifeng Xiao, New Mexico State Univ. (United States)

Abstract

The estimation or recovery of the index of refraction from optical scatter off a target's surface is a task of pivotal importance for remote sensing applications such as material classification and target recognition. Previous studies show that optical polarimetry is an effective approach for index of refraction estimation in remote sensing applications. However, straightforward polarimetric models based on Fresnel inversion are limited to specular targets and surface scattering. In this paper, we propose a method to estimate the refractive index in the presence of an unknown, unpolarized diffuse scattering component in the polarimeter measurements. The effect of the diffuse scattering is modeled following the Kubelka-Munk theory, which describes the polarization phenomena of non-specular materials including both contributions of surface and diffuse scattering. Our simulation results indicate that the recovered indices of refraction without consideration of diffuse scattering will introduce significant errors, especially for dielectric materials. Our method can accurately recover the complex index of refraction for both specular and non-specular targets in both visible and infrared spectrum involving surface and diffuse scattering.

9613-34, Session 10

Remotely sensing the photochemical reflectance index (pri)

Vern C. Vanderbilt, NASA Ames Research Ctr. (United States); Craig S. T. Daughtry, U.S. Dept. of Agriculture (United States); Robert P. Dahlgren, NASA Ames Research Ctr. (United States)

In remote sensing, the Photochemical Reflectance Index (PRI) provides insight into physiological processes occurring inside the leaves in a stand of plants. Developed by Gamon et al., (1990 and 1992), PRI evolved from laboratory measurements of the reflectance of individual leaves (Bilger et al.,1989). Yet in a remotely sensed image, a pixel measurement may include light from both reflecting and transmitting leaves.

We conducted laboratory experiments comparing values of PRI based upon polarized reflectance and transmittance measurements of water and nutrient stressed leaves. We illuminated single detached leaves using a current controlled light source (Oriel model 66881) and measured the leaf weight using an analytical balance (Mettler model AE 260) and the light reflected and transmitted by the leaf during dry down using two Analytical Spectral Devices spectroradiometers. Polarizers on the incident and reflected light beams allowed us to divide the leaf reflectance into two parts: a polarized surface reflectance and a non-polarized 'leaf interior' reflectance.

Our results underscore the importance when calculating PRI of removing the leaf surface reflection, which contains no information about physiological processes ongoing in the leaf interior. The results show that the leaf physiology information is contained in the leaf interior reflectance, not the leaf transmittance. Applied to a plant stand, these results suggest use of polarization measurements in sun-view directions that minimize the light arriving from transmitting leaves in the sensor field of view.

9613-35, Session 10

The 3MI mission: multi-viewing -channel -polarisation imager of the EUMETSAT polar system - second generation (EPS-SG) dedicated to aerosol and cloud monitoring

Thierry Marbach, European Organisation for the Exploitation of Meteorological Satellites (Germany); Jérôme Riedi, Univ. des Sciences et Technologies de Lille (France); Antoine Lacan, Peter Schluessel, European Organisation for the Exploitation of Meteorological Satellites (Germany)

The Multi-Viewing -Channel -Polarisation Imager (3MI), planned to fly on the EPS-SG platform in the time-frame 2020–2040, is a push-broom radiometer dedicated to aerosol and cloud characterisation for climate monitoring, atmospheric composition, air quality and numerical weather prediction.

The role of clouds in determining climate sensitivity to change is highly uncertain. Hence new cloud observation systems (ground-based and space-borne) are needed for cloud monitoring. Cloud remote sensing must be performed at multiple channels (from UV to microwave) using passive multi-angle observations of the intensity and polarization characteristics of reflected/transmitted radiation and also radiative fluxes inside/above/below clouds.

The purpose of the 3MI is to provide multi-spectral (from 410 to 2130 nm), multi-polarisation (-60°, 0°, and +60°), and multi-angular (10 to 14 views) images of the Earth top of atmosphere (TOA) outgoing radiance. First results from the 3MI synthetic data simulator will be presented.

Although aerosol and cloud characterisation is the primary application, 3MI will further support observation of land-surface characteristics which will benefit from the enhanced directional and polarisation measurements and provide a better understanding of the Earth radiative forcing budget.

3MI will benefit from the synergy of other instruments flying also onboard EPS-SG. Measurements from thermal infrared channels will be available from the METimage and IASI-NG instruments. Furthermore, the Sentinel-5 will provide information from the ultra-violet to the short-wave infra-red, through a coarser horizontal sampling. The synergy with these instruments will also support 3MI with beneficial cross-calibration as 3MI will not have an onboard calibration and its radiometric performance will rely on vicarious calibration.

9613-36, Session PWed

System of polarization phasometry of polycrystalline blood plasma networks in mammary gland pathology diagnostics

Natalia I. Zabolotna, Vinnytsia National Technical Univ. (Ukraine); Bogdan P. Oliinychenko, Medivin (Ukraine); Kostiantyn O. Radchenko, Anastasiia K. Krasnoshchoka, Olga K. Shcherba, Vinnytsia National Technical Univ. (Ukraine)

Nowadays, laser polarimetry methods and systems that start to be used for diagnostic purposes in medicine, allow to get qualitatively new results in research into morphological and functional state of biological objects.

In this paper the effectiveness indexes of the direct polarization phasometry system are determined for diagnosing mammary gland pathology by direct phase mapping of human plasma films with the subsequent statistic, correlation, and fractal estimation of the received phase map structure. This has revealed the objective possibility of phase detection of breast pathological states by using statistical, correlation and fractal parameters characterizing optical - anisotropic component of plasma proteins.

The experiment was conducted in the traditional direct phase polarimetry system, including: He-Ne laser, quarter-wave plates, collimator optics, a polarizer and an analyzer, a micro lens, a research sample and a CCD camera connected to the computer.

The object of research was a series of plasma stroke samples taken from three groups of patients - healthy (group 1), with mastopathy (Group 2), patients with breast cancer (group 3). Further experimental research of coordinate structure distribution of phase shifts between orthogonal states of polarization of laser microscopic images of crystallized amino albumin and globulin plasma films networks for all patient groups was performed. This study was followed by determining quantitative criteria for phase differentiation of pathological breast conditions (statistical, correlation and spectral moments of 1st - 4th orders). It has been established that spectral and correlation moments do not allow differentiating the state of the object, so it is advisable to use statistic estimation.

To characterize information content of direct phasometry method for the diagnosis of benign and malignant breast changes, primary and secondary operating characteristics: sensitivity, specificity, accuracy, positive outcome predictability, negative result predictability were defined.

High self-descriptiveness level in mapping distributions of phase shifts in plasma films by using a common statistic moment for diagnosing benign and malignant breast changes has been discovered.

From the obtained data about statistic structure of phase maps of plasma films laser images for all groups of healthy and sick patients, the unbiased opportunity for not only emergency diagnosing mammary gland pathology, but also differentiating their severity. Sensitivity and specificity of statistical moment of 2nd order phase maps made respectively: in diagnosing benign breast changes 77% and 83%; in diagnosing malignant changes in breast 91% and 86%; in differentiating benign and malignant breast changes 86% and 80%. Accordingly, a high level of reliability and validity of the proposed method has been stated.

9613-37, Session PWed

A portable imaging Mueller matrix polarimeter based on a spatio-temporal modulation approach: theory and implementation

Israel J. Vaughn, College of Optical Sciences, The Univ. of Arizona (United States); Oscar G. Rodriguez, Mohan Xu, The Univ. of Arizona (United States); J. Scott Tyo, College of Optical Sciences, The Univ. of Arizona (United States)

Imaging polarimeters have been largely used for remote sensing tasks, and most imaging polarimeters are division of time or division of space Stokes polarimeters. Imaging Mueller matrix polarimeters have just begun to be constructed which can take data quickly enough to be useful for remote sensing tasks. We have constructed a full Mueller matrix polarimeter utilizing a hybrid modulation approach (modulated in both time and space) based on a micro-polarizer array camera and rotating retarders.

We introduce a channel structure derived from the spatio-temporal modulation and optimize over control parameters to minimize channel crosstalk. We present an instrument utilizing this hybrid approach and various reconstruction schemes tailored to specific constraints. Furthermore, we present example data acquired with the instrument and some specific examples of reconstruction of that data.

9613-38, Session PWed

Polarization modulation for the Atacama Cosmology Telescope using continuously rotating half-wave plates

Jonathan T. Ward, Mark J. Devlin, Univ. of Pennsylvania (United States); Robert Thornton, West Chester Univ. of Pennsylvania (United States); Jeffrey McMahon, Kevin Coughlin, Fletcher Boone, Charles Munson, Rahul Datta, Univ. of Michigan (United States)

Among the greatest open challenges confronting the field of contemporary physics is understanding the first moments of the universe, the properties of it's contents, the formation of structure under the influence of gravity, and the nature of dark energy. A principal method of improving our understanding of these topics originates through direct measurement of the Cosmic Microwave Background (CMB). The Atacama Cosmology Telescope (ACT) makes high resolution measurements of the CMB and it's polarization. Measuring the polarization allows cosmologists to better understand the structure of the universe and the moments immediately following the Big Bang. To achieve polarization measurements at large angular scales, ACT utilizes continuously rotating half-wave plates (HWPs). The HWPs are controlled using a custom air bearing system coupled to high-performance drive motors, with position and frequency readout handled by a self-built encoder. Such measurements will allow ACT to probe the faint B-mode polarization signal created by primordial gravitational waves, a key piece of evidence for the theory of cosmological inflation. Details of the mechanical design, control system, encoder readout, and installation are discussed as well as preliminary performance tests that highlight the stability and reliability of the instrument. The optical properties and performance of the achromatic, birefringent, metamaterial, silicon HWPs are also presented. The complete system highlights innovative methods in polarization science, both in the field of cosmology and for other applications.

9613-39, Session PWed

Characterizing the kinetics of suspended cylindrical particles by polarization measurements

Ran Liao, Nan Zeng, Honghui He, Hui Ma, Tsinghua Univ. (China)

Polarization responses sensitively to the microstructures in the samples such as the tissues, and has promising potential to retrieve the information. However, for the fast changing sample such as the suspended algae in the water, the kinetics of the particles also influence the scattered polarization. The present paper will show our recent results to extract the information about the kinetics of the suspended cylindrical particles from polarization measurements. The sample is the aqueous suspension of the fiber glasses stirred by a magnetic stirrer. We measure the scattered polarization of the glass fibers by use of a simultaneous measurement system and obtain the time series of two polarization components, i.e., VV and VH. By use of correlation analysis, we obtain the correlation times of both VV and VH, which change with the concentration and the stirring speed of the sample. We find that the correlation time of VV and VH are different, which indicates that VV and VH describe different motion of the fibers. Also, the time corresponding to the maximum of the cross-correlation function of VV and VH has a shift which changes differently as we change the concentration and the stirring speed of the sample. Preliminary analysis shows that these time constants, i.e., the correlation time and the time shift, may originate from the translation and rotation kinetics of glass fibers in the flow field.

9613-40, Session PWed

Identification of soot particles in air using polarization scattering method

Da Li, Nan Zeng, Maomao Zeng, Ran Liao, Hui Ma, Tsinghua Univ. (China)

Light scattering in atmosphere can change optical polarization properties. Analysis and Measurement on interaction of polarized light with atmospheric particulates can provide important information to evaluate the atmospheric composition and conditions. In this paper, we propose a polarization character focusing on the evaluation of soot content in the air, based on our polarized photon scattering simulation program. The simulation results demonstrate how the polarization parameter at a specific scattering angle can identify the soot particles from the other air pollutants. Compared with non-polarization optical measurement, polarization characterization can enhance the contrast of distinguishing different type particles and also can be applied in a wide particle size range.

Conference 9614: Laser Communication and Propagation through the Atmosphere and Oceans IV

SPIE. OPTICS+ PHOTONICS OPTICAL ENGINEERING+ APPLICATIONS

Monday - Wednesday 10–12 August 2015

Part of Proceedings of SPIE Vol. 9614 Laser Communication and Propagation through the Atmosphere and Oceans IV

9614-1, Session 1

Estimation of turbulence strength, anisotropy, outer scale and spectral slope from an LED array *(Invited Paper)*

Max Segel, Szymon Gladysz, Christian Eisele, Rui Barros, Fraunhofer-Institut für Optronik, Systemtechnik und Bildauswertung (Germany)

Decorrelation of tip/tilt information is of fundamental importance in imaging and laser propagation through the atmosphere without a cooperative beacon on the target. Applications include laser-guide-star adaptive optics, tracking of fast-moving objects and multi-beam laser communications. We compute gradient-tilt anisoplanatism for the case of spherical-wave propagation. The model is then fitted to data obtained from an LED array observed from a 110-m distance. We show how with this data one can estimate several properties of atmospheric turbulence: turbulence strength, anisotropy, outer scale and spectral slope.

9614-2, Session 1

Blob identification algorithms applied to laser speckle to characterize optical turbulence

Galen Cauble, David T. Wayne, Space and Naval Warfare Systems Ctr. Pacific (United States)

Laser beam speckle resulting from atmospheric turbulence contains information about the propagation channel. The number and size of the speckle cells can be used to infer the spatial coherence and thus the Cn2 along a path. The challenge with this technique is the rapidly evolving speckle pattern and non-uniformity of the speckle cells. In this paper we investigate modern blob counting techniques used in biology, microscopy, and medical imaging. These methods are then applied to turbulent speckle images to estimate the number and size of the speckle cells. Speckle theory is reviewed for different beam types and different regimes of turbulence. Algorithms are generated to calculate path Cn2 from speckle information and path geometry. To test our algorithms, we use WaveProp software to generate propagation simulations with known turbulence conditions. Additionally, the algorithms are tested on speckle images from experimental data collected over a turbulent 1km path.

9614-3, Session 1

Stereo image motion monitor for atmospheric mitigation and estimation

Kristofor Gibson, SPAWAR Systems Ctr. (United States)

The knowledge of the turbulence strength in the atmosphere is important for many applications. Imagery in the atmosphere experience significant blur when the turbulence is strong. This can be automatically improved (without user intervention) if the turbulence strength is known. The performance of a high-power laser emitting in the atmosphere can be predicted if the statistics of the turbulence strength is known. If not predicted correctly, the laser may unintentionally destroy a target or fail to be able to disable a target.

In this article, we review existing methods that estimate turbulence strength, provide a more in depth error analysis, and propose a new method for estimating and mitigating turbulence in the atmosphere. We focus on methods that are passive in design in order to prevent detection in surveillance scenarios and tactical situations. We also propose a new method, stereo image motion monitor (SIMM) which is a system containing two independent apertures. Our goal in this approach is threefold: 1) We can measure r0 using the DIMM method 2) We can simultaneously estimate r0 individually for each aperture and 3) We have multiple views of the same scene thus can increase the number of frames used in turbulence mitigation methods.

9614-4, Session 1

Imaging through turbulence using a plenoptic sensor

Chensheng Wu, Jonathan Ko, Christopher C. Davis, Univ. of Maryland, College Park (United States)

Atmospheric turbulence is a natural disturbance affecting remote imaging along paths near the ground. It causes time varying inhomogeneity of the refractive index of air and therefore disrupts the propagation of optical signals from the object to the viewer. Under circumstances of deep turbulence or strong turbulence, the object is hard to recognize through direct imaging. And conventional methods will have degraded results, such as increased time for performing lucky imaging and more complicated de-blurring process at the software layer. We propose the approach of using a plenoptic sensor after a telescope for imaging remote targets through turbulence. The plenoptic sensor uses a shared objective lens and a microlens array to form a mini Keplerian telescope array. Thus, the image obtained by a conventional telescope will be separated into an array of images that contains multiple copies of the object's image and less correlated turbulence disturbances. Then a high-dimensional lucky imaging algorithm can be performed based on the collected video from the imaging camera. The corresponding algorithm will select the most stable pixels from various image cells and assemble the image of the object as if there is only a weak turbulence effect. Then, by comparing the reconstructed image with the recorded images in each MLA cell, the difference can be regarded as the turbulence effects. As a result, the retrieval of the object's image and extraction of turbulence effect can be performed simultaneously. The system structure, algorithm and experimental results will be demonstrated in this presentation.

9614-5, Session 2

Super-resolution in the scintillation imaging through turbulence

Mikhail I. Charnotskii, National Oceanic and Atmospheric Administration (United States)

Fluctuations of the images of stationary incoherent objects viewed through turbulence normally are treated as a detrimental noise, and variety of techniques have been suggested to mitigate this nuisance. In this talk we discuss the concept of the Scintillation Imaging (SI), when, instead of attempting to recover the proper object image, image fluctuations are used to gain the information about the object. It appears that due to the "third constraint" on the turbulent point spread function [Charnotskii, OE, 52, 046001, 2013] SI has differentiating properties and emphasizes the areas of the high contrast of the object. We show, that the SI can unveil the turbulence super-resolution effect that was originally discovered in [Charnotskii, et. al. JOSA A, 7, p. 1345, 1990]. The peculiarities of the SI are discussed using a simple example of a sinusoidal grating object. In this case SI consists of the uniform background and harmonic components at the double spatial frequency. The contrast of this SI is not sensitive to the contrast of the object, and amplitude of the harmonic component vanishes when target wave number exceeds the diffraction limit. However, the scintillation background persists even when the grating cannot be

resolved by the imaging aperture. This is a manifestation of the turbulent super-resolution when light scattering by turbulent eddies makes it possible for the imaging aperture to collect high spatial frequencies of the object. We will discuss possible applications of this effect for the imaging of homogeneous random textures, such agricultural and forestation landscapes.

9614-6, Session 2

Using aperture partitioning to improve scene recovery in horizontal long-path speckle imaging

Jeremy P. Bos, Air Force Research Lab. (United States); Brandoch Calef, Boeing LTS Inc. (United States)

Recently, Calef [1] showed that a novel aperture-partitioning optic could be used to vastly improve imagery of space object when in situations where the ratio of aperture size to coherence radius was very large. These situations are common when either the aperture is large or the turbulence is strong. Borrowing from the terminology of interferometry, the presence of multiple independent coherence cells across the aperture results in baseline redundancy. These redundancies further blur imagery and reduce the effectiveness of speckle imaging. Calef's partitioned aperture optic removes this redundancy by dividing aperture into annular rings; each creating a separate image. Phase estimates at each spatial frequency are acquired using the bispectrum method [2] and combined by weighting each estimate by the SNR of the estimate.

In this work, we explore the use of a similar partitioned aperture optic to improve speckle imaging in daytime horizontal imaging scenarios. In these scenarios, the turbulence is typically strong but the aperture sizes more modest. Thus, outright baseline redundancy is less severe. On the other hand, imaging through a distributed turbulence volume introduces severe anisoplantism. In some scenarios, the isoplanatic angle may be on the order of the diffraction-limit. In previous presentation at this conference [3,4,5] we successfully demonstrated the application of speckle imaging on both simulated [4] and field data [5]. In this presentation we will begin by reviewing both the reasoning and technique of aperture partitioning. Next, we will describe straightforward modifications to our horizontal imaging simulation model and show image sequences from each of the partitioned along with the image of a full aperture. After briefly describing the reconstruction process we will present examples of reconstructed images and compare results objectively via the residual MSE of image sets to a diffraction-limited reference.

9614-7, Session 2

Modeling and simulation of anisoplanatic (space-variant) imaging through the atmosphere

Colin Reinhardt, Space and Naval Warfare Systems Ctr. Pacific (United States)

We wish to synthesize computer-generated images which are as physically-realistic as possible. For terrestrial imaging scenarios we must account for the physical effects of the earth's atmospheric boundary layer on EO/IR wave propagation between remote objects and the imaging device. These effects can vary pixel-by-pixel depending on the optical path lengths between the imager and objects subtended by each pixel instantaneous field-of-view (IFOV), on the path height above ground (or water) and the path elevation angle to the horizontal, and on the intervening atmospheric microphysical properties. When an image sensor array has a wide enough field-of-view (FOV) that there is significant variation in the optical path length to objects imaged by the different pixels, or such that the sensor full angle FOV is greater than the isoplanatic angle of the atmospheric turbulence, then the typical assumptions of linear space/shift-invariance (LSI) which allow the representation of the output image as the convolution of the input image and a single point-spread function (PSF) are no longer valid. Instead we must use the space-variant (or shift-variant) (SV) formulation. We present a physically accurate modeling and simulation algorithm which solves the SV imaging problem in a computationally-affordable manner, with a significant increase in image fidelity. Our method includes the effects of atmospheric aerosols (extinction and multiple-scatter) along the varying optical paths to objects subtended by each pixel, including slant-path geometries, and also the effects of optical turbulence under anisoplanatic imaging conditions. We also present useful uncertainty bounds on the results.

9614-8, Session 2

Propagation dynamics of optical vortices in turbulent atmosphere

Haiyan Wang, Nanjing Univ. of Science and Technology (China)

Due to the conservation of topological charges and quantum secrecy, laser beams embedded optical vortices can be widely used in Optical communication. Optical vortices may exhibit propagation dynamics similar to hydrodynamic vortex phenomena. Numerical methods are used to describe and investigate the interaction between optical vortices and the turbulence of atmosphere when laser beams propagating through turbulent atmosphere. We demonstrate that the turbulence of atmosphere may affect the orbit of optical vortices. We also describe the properties of the unsymmetrical discrete optical vortices.

9614-10, Session 3

Spread and wander of a laser beam propagating through anisotropic atmospheric turbulence

Italo Toselli, Olga Korotkova, Univ. of Miami (United States)

On propagation of a laser (TEM00) beam at high altitude it may traverse the regions of stratified turbulence, and hence may experience its anisotropic effects. Naturally such anisotropy occurs in x-z or y-z planes, where x and y are the mutually orthogonal horizontal directions and z is the vertical direction. On assuming that the beam propagates along a horizontal direction y we employ the Rytov method together with the Markov approximation for derivation of the closed-form expressions for the short and long terms of the averaged intensity of the beam and deduce its spread and wander, along directions x and z. For our derivations we use the recently introduced anisotropic non-Kolmogorov spectrum for taking into account the distribution of crude and fine structures of turbulence in addition to the anisotropy

9614-35, Session 3

Enhanced backscatter analysis for long-range optical tracking in deep turbulent conditions

Christopher A. Smith, Sara B. Belichki, Ronald L. Philips, Larry C. Andrews, Townes Laser Institute (United States) and CREOL, The College of Optics and Photonics, Univ. of Central Florida (United States); David T. Wayne, Space and Naval Warfare Systems Ctr. Pacific (United States)

The usage of long-range optical systems for tracking applications encounters regions of deep turbulence throughout propagation. Such conditions lead to the inability to remain on target for a tracked object due to scintillation. To mitigate this issue, an enhanced backscatter (EBS) optical system is utilized as a means of keeping alignment while characterizing turbulent conditions. EBS is detected through the means of image processing algorithms that capture the returning constructive interference from the target. This paper evaluates EBS optical systems using a retro-reflector for both 1 kilometer and 13 kilometer ranges in order to validate theoretical models that typify atmospheric turbulence regarding low-ground and slant path propagation. Meteorological conditions are also included in the empirical data obtained for the analysis of atmospheric conditions that contribute to non-homogenous turbulent conditions along the path. Lastly, scintillation index measurements derived from image processing algorithms along single and double pass are assessed to determine the fidelity of such a system for optical tracking.

9614-11, Session 4

Lunar laser ranging: atmospheric limitations and upgrading SLR stations

Douglas G. Currie, Univ. of Maryland, College Park (United States)

The Lunar Laser Ranging Program (LLRP), using data obtained by ranging to the retroreflector arrays deployed during the Apollo missions, has produced most of the best tests of Gravitation and General Relativity. This data is being used to address theories of Dark Matter and Dark Energy. With deployment of the next generation anchored "Lunar Laser Ranging Retroreflector Arrays for the 21st Century" (LLRRA-21), the accuracy of the science results will ultimately be determined by the effects of the earth's atmosphere through which the laser pulse propagates. The ultimate limitations for range measurements will be the jitter, or short term fluctuations, for the single photoelectron (SPE) ranges and the biases of the normal points produced by multiple ranges taken in a short time interval. The former is due to turbulence and the cells with different temperatures. The long term latter effect is caused by atmospheric spatial gradients in temperature and pressure. The recent improvements in the estimates of both the SPE jitter using the GLAD software and additional analysis that improved the estimates of the magnitude of bias estimates and the accuracy of the these estimates. At present, the several Satellite Laser Ranging (SLR) stations have the equipment to accomplish the most accurate laser ranging. We will discuss the relation between the atmospheric propagation effects and the existing equipment configurations of these several SLR stations. Finally, we will address some other applications of the effects of the atmospheric induced jitter, in particular, the role in 3D imaging of satellites.

9614-12, Session 4

Different atmospheric effects causing FSO link attenuation: experimental results and modelling in Czech Republic

Ondrej Fiser, Institute of Atmospheric Physics of the ASCR, v.v.i. (Czech Republic) and Czech Technical Univ. in Prague (Czech Republic); Vladimir Brazda, Institute of Atmospheric Physics of the ASCR, v.v.i. (Czech Republic)

Different Atmospheric Effects Causing FSO Link Attenuation - Experimental Results and Modelling in Czech Republic

The six year FSO link attenuation measurement concurrently with most important meteorological parameters was performed at our mountain observatory Milesovka. In this contribution we summarize and classify different atmospheric phenomena after the FSO link attenuation quantity. For all particular phenomena the CD curves, typical events and simple dependences on relevant atmospheric parameter(s) are presented. We consider the following phenomena (approximate attenuation in dB in brackets):

1. Fog and cloud (hundreds dB)

This attenuation is modelled in the dependence on meteorological visibility. Examples distinguishing cloud and fog are discussed. Visibility is measured by sensors as well as by videocamera, results are compared.

2. Rain and snow (tens dB)

Rain rate as an attenuation predictor is measured by rain gauge and videodistrometer.

3. Atmospheric turbulence (unit dB)

We evaluate this attenuation through the signal redistribution due to refractivity index in-homogeneity in the dependence on both: structure index and Rytov formula as well as on selected wind parameters derived from 3D sonic anemometer. Correlation of both approaches is acknowledged.

4. Clear air attenuation due to water vapour (unit dB or less)

So called "Clear air attenuation" is caused by invisible atmospheric gasses especially through water vapour. This attenuation depends on the air humidity, temperature and pressure or on "sonic temperature," which is measured by the 3D sonic anemometer.

9614-13, Session 5

Determining beam properties at an inaccessible plane using the reciprocity of atmospheric turbulence

William Nelson, Chensheng Wu, Christopher C. Davis, Univ. of Maryland, College Park (United States)

A turbulent, atmospheric channel can be considered to be exactly reciprocal at any instance in time. Reciprocity is a powerful property that can be used to compensate for the distortions caused by turbulence such as beam scintillation, spreading, and wander. In free-space optical communication systems, reciprocity can be used by phase conjugating a beacon beam propagating from the receiver to the transmitter. However, this strategy would not work in directed energy (DE) systems where the target is uncooperative and the transmitter and receiver are located in the same plane. Theoretical work by Lukin and Charnotskii [Sov. J. Quantum Electron., 12(5), 602 (1982)] has shown that reciprocity principles indicate that certain properties of the beam incident on a target fluctuate synchronously with the intensity distribution reflected from the target. Here we extend this analytically pure treatment using a combination of simulations and experiments. We show that there exists a correlation between the intensity imaged by the receiver and properties of the beam incident on the target. Furthermore, we find that the intensity at a specific location can be used to drive an adaptive optics system that corrects for atmospheric distortions.

9614-14, Session 5

Entropy studies on beam distortion by atmospheric turbulence

Chensheng Wu, Jonathan Ko, Christopher C. Davis, Univ. of Maryland, College Park (United States)

When a beam propagates through atmospheric turbulence over a known distance, the target beam profile deviates from the projected profile of the beam on the receiver end. Intuitively, the unwanted distortion indicates the information carried by the atmospheric turbulence itself. And this information is crucial for guiding adaptive optic systems and improving beam propagation results. In this paper, we propose a 2D entropy function based on the image from a plenoptic sensor to describe the information about atmospheric turbulence. When no correction is applied, the value of the entropy function will increase when the turbulence gets stronger and decrease when the turbulence gets weaker. And at the same level of turbulence, when corrections are applied, the entropy function will decrease with good correction and increase with bad correction. Therefore, the entropy function can be used to analyze the turbulence distortion and evaluate performance of AO systems. In fact, it serves as an image metric that can tell the improvement of beam correction in each iteration step. In addition, it points out the limitation of the AO system at optimized correction as well as the minimum information needed for wavefront sensing to achieve certain levels of correction. In this paper, we will demonstrate the definition of the entropy function and how it is related to evaluating information (randomness) carried by atmospheric turbulence and how this information (randomness) is suppressed by some AO devices in performing correction.

9614-15, Session 5

Analogue holographic wavefront sensor: a performance analysis

Andreas Zepp, Szymon Gladysz, Rui Almeida de Sa Barros, Fraunhofer-Institut für Optronik, Systemtechnik und Bildauswertung (Germany); Wolfgang Osten, Univ. Stuttgart (Germany) and Institut für Technische Optik (Germany); Karin U. Stein, Fraunhofer-Institut für Optronik, Systemtechnik und Bildauswertung (Germany)

The efficiency of laser communications systems is significantly limited by atmospheric effects. Notably challenging scenarios like a long horizontal path or strong scintillation lead to high failure rates of the electro-optical systems. Adaptive optics (AO) methods and components developed for astronomical applications cannot fulfill these higher requirements.

The so-called Holographic Wavefront Sensor (HWFS) is a promising alternative for measuring the wavefront deformation of a laser beam. The basic elements of the HWFS are a diffraction pattern and a fast photodetector like a photodiode array. With these components the aberrations present in the beam are measured directly. The advantages of the HWFS are the high bandwidth (MHz range) and the possibility to use it in strong turbulence where scintillation is a limiting factor for the SHS.

In this paper we show the realization of an analogue HWFS. Core of the sensor is a photosensitive plate. We discuss the benefits and disadvantages in comparison to the digital HWFS. To analyze the performance of the sensor, we studied the effect of residual tip / tilt on the sensor response and the dependency on the detector size. For the challenging applications like laser communications the behavior of a wavefront sensor in the presence of scintillation is a very important criterion. We present experimental results to analyze the influence of scintillation on the analogue HWFS. We are now working on integration of the HWFS in an AO system. In the field of laser communications this can lead to optimized fiber coupling and with this to higher bandwidths and a better light efficiency.

9614-16, Session 5

Atmospheric turbulence induced by hot metal objects

Miranda van Iersel, TNO (Netherlands); Henny E. T. Veerman, Alexander M. van Eijk, TNO (Netherlands)

A CUBI is a simple geometric metal object that is placed in an outdoor environment. The (daily) temperature evolution of the individual facets is monitored as function of environmental parameters, such as solar irradiance and ambient temperature. This provides insight in the parameters that have the strongest effects on the thermal signature of the CUBI. The CUBI is also imaged by thermal cameras, which provide insight in the amount of air turbulence that is generated by the radiance of the hot facets, as well as the effect of this turbulence on image quality. The amount of turbulence can be compared with the ambient turbulence as calculated by standard bulk theories.

9614-17, Session 5

An adaptive optics approach for laser beam correction in turbulence utilizing a modified plenoptic camera

Jonathan Ko, Chensheng Wu, Christopher C. Davis, Univ. of Maryland, College Park (United States)

Adaptive optics has been widely used in the field of astronomy to correct for atmospheric turbulence while viewing images of celestial bodies. The slightly distorted incoming wavefronts are typically sensed with a traditional Shack-Hartmann sensor and then corrected with a deformable mirror. Although this approach has proven to be effective for astronomical purposes, a new approach must be developed when correcting for the deep turbulence experienced in ground to ground based optical systems. We propose the use of a modified plenoptic camera as a wavefront sensor capable of accurately reconstructing an incoming wavefront that has been significantly distorted by strong turbulence conditions (Cn2>10-13 m-2/3). An intelligent correction algorithm can then use this reconstructed wavefront information to drive a deformable mirror capable of correcting the major distortions in the wavefront. After the large distortions have been corrected, a secondary mode utilizing a stochastic parallel gradient descent algorithm can take over to fine tune the wavefront correction. This two-part algorithm can find use in free space optical communication systems as well as for image correction purposes.

9614-18, Session 6

Estimating refractive index structure parameter (Cn2) profiles in the atmosphere: a framework based on fractal interpolation *(Invited Paper)*

Sukanta Basu, Ping He, North Carolina State Univ. (United States)

The refractive index structure parameter (Cn2) is commonly used for the quantification of optical turbulence intensity. Over the years, various specialized instruments (e.g., thermosonde, SCIDAR) have been developed for the accurate measurement of Cn2 in the atmosphere. In parallel, a number of empirical models have also been proposed for the reliable estimation of Cn2. For example, the popular Submarine Laser Communications (SLC) model was developed based on averaged Cn2 measurements on Mt. Haleakala, Hawaii. In contrast, the Critical Laser Enhancing Atmospheric Research I (CLEAR I) model was based on observational data from the New Mexico desert. Given that these empirical Cn2 models are site-specific and time-invariant, their applicability to the other regions of the world is questionable.

In this study, we propose a novel Cn2 estimation framework and demonstrate its prowess by validating our predicted results against the measured Cn2 data from the Hawaii 2002 thermosonde campaign by the Air Force Research Laboratory. The salient features of this framework are: (i) ability to capture realistic spatio-temporal variations of Cn2 based on local meteorological settings; (ii) assumption of quasi-universal vertical scaling of temperature fields; (iii) application of the so-called fractal interpolation function technique for statistical downscaling; and (iv) utilization of coarse-resolution temperature and pressure profiles. These profiles can be readily obtained from weather balloons (aka radiosondes), satellite-based soundings (e.g., AIRS), and numerical weather prediction model-generated

output from across the globe.

We would like to emphasize that our proposed Cn2 estimation approach only requires temperature and pressure profiles as input. In contrast, the well-known Cn2 model proposed by Air Force Geophysics Laboratory (AFGL) relates Cn2 to the profiles of wind speed, temperature, and pressure. Since the measurement and/or modeling of wind speed is usually challenging, our approach is expected to be less error-prone and more reliable than the AFGL model.

9614-19, Session 6

Mesoscale modeling of optical turbulence utilizing novel Cn2 parameterizations

Ping He, Sukanta Basu, North Carolina State Univ. (United States)

Small-scale fluctuations of refractive index, commonly known as optical turbulence, can have significant impacts on optical wave propagation in the atmosphere (e.g., beam wandering, scintillation). The intensity of optical turbulence is characterized by the refractive index parameter (Cn2). Accurate numerical modeling of Cn2 is a challenging task since one needs to capture atmospheric scales ranging from the inertial sub-range (on the order of 1 m) to the propagation range (on the order of 10s or 100s of km). This modeling difficulty can be further aggravated by the presence of complex atmospheric phenomena (e.g., coherent wake vortices, low-level jets).

In this study, we perform state-of-the-art mesoscale modeling of optical turbulence utilizing two novel Cn2 parameterizations. One of these parameterizations is based on the fractal interpolation function technique and utilizes a quasi-universal vertical scaling of temperature fields. We utilized high-resolution observational data for its development. The other parameterization has its root in the so-called gradient-based similarity theory. We have developed this particular parameterization using an extensive synthetic turbulence database. Numerous direct numerical simulations (DNS) and large-eddy simulations (LES) were performed to create this unique database. It contains both continuous and intermittent turbulence events and spans a wide-range of Reynolds and Richardson numbers.

In order to document the strengths and weaknesses of our newly proposed Cn2 parameterizations, we have selected several realistic cases from the Hawaii 2002 thermosonde campaign by the Air Force Research Laboratory. The Weather Research and Forecasting (WRF) model (coupled with the Cn2 parameterizations) is employed to simulate these cases. Relatively high spatial resolution (innermost grid with one km grid-spacing) is used for all the runs. For model validation, we primarily make use of the thermosonde-based Cn2 and other meteorological data. For completeness, we also report the performance of a few conventional Cn2 parameterizations (e.g., HV-5/7, AFGL) in this study.

9614-20, Session 6

The Havemann-Taylor Fast Radiative Transfer Code (HT-FRTC) and its Applications

Jean-Claude Thelan, Stephan Havemann, Warren J. Lewis, Met Office (United Kingdom)

The HT-FRTC is a component of the Met Office Neon Tactical Decision Aid (TDA). Within Neon the HT-FRTC has for a number of years been used to predict the IR apparent thermal contrasts between different surface types as observed by an airborne sensor. To do this, the FRTC is supplied with the inherent temperatures and spectral properties of these surfaces (i.e. ground target(s) and surrounding background).

A strength of the HT-FRTC is its ability to take into account the detailed properties of the atmosphere, which in the context of Neon tends to be provided by a Numerical Weather Prediction (NWP) forecast model. Incorporated into the HT-FRTC is an exact treatment of atmospheric scattering based on spherical harmonics. This allows the treatment of different aerosol and cloud types. Recent developments even account for rain and falling snow.

The HT-FRTC has been extended to cover the spectral range of the Photopic and NVG sensors. One aim here is to give the user guidance on the expected light levels, especially at night, again taking the atmospheric conditions into account. A recent development allows such predictions during twilight.

The user of the code can add new sensors by simply supplying files that contain their sensor's spectral properties.

The HT-FRTC works in Principal Component space which significantly reduces the computational requirements regarding memory and time.

Other applications of the HT-FRTC include simulations of satellite and airborne hyperspectral sounders. The HT-FRTC is also used as the forward model in variational retrieval schemes of atmosphere and surface parameters.

9614-21, Session 6

A parameterization of littoral fog

Joshua J. Rudiger, SPAWARSYSCEN Pacific: San Diego (United States); John S. deGrassie, Space and Naval Warfare Systems Ctr. Pacific (United States)

A microphysical parameterization for fog is developed based upon meteorological measurements such as visibility, droplet number concentration, liquid water content, temperature, relative humidity and atmospheric pressure. The potential use of shipboard laser weapons and increasing use of free-space optical communication systems in many different operating environments require accurate models of aerosols and how they affect these systems. Developing a fog model increases the predictive effectiveness for assessing a given system's performance. It will, for example, aid in predicting the performance of imaging systems, the amount of power scattered off-axis, and, more generally, increase the accuracy of the optical properties such as extinction and absorption. Here we develop a microphysical parameterization for fog modeling applications based upon observations of littoral fog events thereby increasing the predictive accuracy of atmospheric propagation models.

9614-22, Session 7

The study of full link duplexing of UV NLOS scattering channel

Gang Chen, Linchao Liao, Univ. of California, Riverside (United States)

In this paper, the full link duplexing of UV NLOS scattering channel is studied comprehensively. We first conduct a serial of experiment to investigate the self-interference effect of different wavelengths in UV-C band under different configuration geometries. Then we propose a method for self-interference cancelation (SIC) of UV NLOS communication system. Through simulation, it is shown that both the throughput and point-to-point bit-error-rate (BER) of UV NLOS mesh network are obviously improved after adopting the proposed SIC method.

9614-23, Session 7

Massive MIMO visible light communication system via hemispherical lens on hemispherical beehive structure receiver

Gang Chen, Tian Iang, Univ. of California, Riverside (United States)

With the development of internet of things, Visible Light Communication (VLC) is the missing piece of this inevitable technology. However, current VLC systems lack the adequate date rate and reliability. By utilizing massive

Multiple Input Multiple Output (MIMO) technology with the proposed hemispherical lens on hemispherical beehive structure (HBS) receiver, we can achieve the significant diversity channel gain in our VLC system which increases the communication speed substantially. Via classical optics, we are able to derive a model to determine the channel gain of the HBS receiver based on the number of indoor transmitter. The simulation result shows images from transmitters to HBS receiver are distinguishable based on different angle of incidence which confirms that there is a significant spatial diversity for the proposed VLC systems.

9614-24, Session 7

Optical design of communication simulator for orbital angular momentum based free-space link with an adaptive optics receiver

Alonzo J. Espinoza, Garret Odom, Wenbo Gao, Milorad Cvijetic, Yuzuru Takashima, The Univ. of Arizona (United States)

Free-space optical links employing Orbital Angular Momentum (OAM) multiplexing is gathering attention because of its ability to spatially multiplex a number of modes by utilizing orthogonality of wavefront structure of Laguerre-Gaussian (LG) modes. Thus enhancement in data rate is expected for both classical and quantum communication channels. Since the multiplexing is based on the phase profile of the wavefront, optical aberration induced by air turbulences increases cross talk among the modes. This phase aberration is considered as one of the obstacles which prevents OAM multiplexed links from being adopted in, for example, ground to ground communication. We determined that the channel capacity is recovered by employing adaptive optics (AO) with sparse selection of OAM modes. In this paper, we report experimental verification of effectiveness of OAM communication with the AO system by using specially made chamber-based simulator which creates air turbulence in a well-controlled manner. The simulator consists of air chamber, air-heater and cooler, transmitter with two OAM modes, and a receiver with an adaptive optics system followed by a single stage Mach-Zehnder based interferometric detector. Computer generated holograms (CGHs) as well as spiral phase plates (SPPs) to create LG modes are designed and fabricated for visible wavelengths for initial testing, and then for 1550nm for final testing. The CGHs and SPPs are fabricated using a mask-less lithography tool. To determine the best option for our application the diffraction efficiency of CGHs and SPPs to produce the desired OAM modes are tested. Cross talk evaluation results and channel capacity estimation are presented.

9614-25, Session 7

The turbulence effects analysis in vehicular optical communication

Gang Chen, Zening Li, Univ. of California, Riverside (United States)

In the vehicular optical communication, hot vehicle exhaust and high-speed air flow can cause severe turbulence to degrade the optical link performance. In this paper, the effects brought in by exhaust and air flow are studied separately. Parameters like exhaust shape, size, temperature as well as the vehicle velocity and sharp have been taken into consideration. Theoretical analysis results based on existing Gamma-Gamma model are compared with the practical measurements. The BER performance has also been discussed under the turbulence case.

9614-26, Session 7

Terrestrial FSO links: channel model classification using neural networks and a case study on the effect of rain

Geetha Prakash, PES Institute of Technology (India); Sripati U. Acharya, Muralidhar Kulkarni, National Institute of Technology, Karnataka (India)

Free Space Optical (FSO) systems are being actively considered as viable options for seamless integration between backhaul optical fiber links and RF or copper links used for last mile connectivity. However, adverse atmospheric conditions can affect the performance and distance over which the link can operate reliably. FSO channel models are chosen based on the atmospheric parameters. In this paper we have developed a novel classification technique using a Radial Basis Function Neural Networks (RBFNN) with a multivariate Gaussian Function to classify FSO channel models. We have also used interpolation techniques, so far not used to model FSO channel models to reconstruct distribution functions for comparison and tested their accuracy by least mean square distance. Simulation results for classification show excellent agreement when compared with the actual distribution function. RBFNN techniques show a Correct Classification Rate (CCR) of above 90 % as compared to 70% with the reconstruction techniques.

FSO systems can suffer outages in the presence of heavy fog, smog and haze. However, since conditions like heavy fog, smog or haze do not manifest at most places in India, these limitations do not limit the widespread deployment of FSO links in our country. However, many places in India (north east and the western coast) see very heavy rainfall for about four to six months in a year. We have studied the effects of rainfall on propagation characteristics of outdoor optical wireless links by taking into account statistics of rainfall in Dakshina Kannada district , Karnataka, India where Surathkal is located which is affected by heavy rainfall for about four to six months in a year. This is broadly representative of many locations on the west coast of India. We observe that the attenuation during heavy rainfall is quite high and may lead to extremely low levels of the received signal or complete erasure of the transmitted data.

Reduced intensity levels could lead to drop in Bit Error Rate (BER) performance. With the validation through simulation in this paper, on the use of Luby Transform (LT) codes in FSO links, we suggest that if LT codes are used in areas prone to rainfall, it would help in the recovery of dropped packets and would also improve the BER performance.

9614-28, Session PWed

Testing resistance modulation formats for FSO communication in turbulent environment, with used simulation box

Ale? Vanderka, Jan Látal, Lukas Hajek, Jan Vitasek, Petr Koudelka, Stanislav Hejduk, Vladimir Va?inek, V?B-Technical Univ. of Ostrava (Czech Republic)

In this article the authors team deals with problems of modulation formats for Free Space Optical (FSO) Communications. FSO communications have high bandwidth, low signal attenuation, quick installation, security, unlicensed band and low cost. In FSO communication occurs due to the influence of atmospheric effect (attenuation, and fluctuation the received power signal, influence turbulence). Here will be dealing modulation schemes OOK (On-off keying) and Subcarrier Intensity Modulation (SIM) based on a BPSK (Binary Phase Shift Keying). In which will studied their characteristic and effect of atmospheric influence on the received signal. This results in decreased Eye-Diagram, Signal-to-Noise Ratio (SNR) and Bit Error Rate (BER). To evaluate the modulation formats in atmospheric turbulence is used simulation box with heat and wind sources.

9614-29, Session PWed

The performance of coherent receiver controlled by the phase lock base in dual rate free-space laser communication

Xiaoping Ma, Jianfeng Sun, Peipei Hou, Wei Lu, Qian Xu, Liren Liu, Shanghai Institute of Optics and Fine Mechanics (China)

The performance of free-space coherent communication is seriously influenced by atmospheric turbulence leading to the distorted wave-front of incident light, the reduced homodyne detection efficiency and bit error rate in the Satellite-to-Ground Laser link. The technique of differential phase shift keying (DPSK) modulation is applied into demodulating phase information in the optical signal receiver. The dual rate free-space receiving structure on the base of Mach-Zehnder delay interferometer without lens is used suitably for differential delay which is equal to the one bit corresponding to a certain data rate.Delay distance at the interference receiver is varied with transmission rate from satellite to ground. Differential information is obtained by the subtraction of the two successive wave-front phases when made to interfere. However, the phase demodulation is extremely sensitive to phase fluctuating. Because of the incident light through atmospheric turbulence, light wave-front because jittered in temporal and spatial domain rapidly. In this paper, the dual rate free-space laser communication receiver with phase lock to stable signal light phase is proposed, increasing the homodyne efficiency and decreasing the bit error rate. The structure are depicted in detail and the experimental results is shown to prove the significance of the phase lock in satellite-to-ground laser link.

Evaluation of FSO link throughput in Qatar under harsh environment

Syed Jawad Hussain, Abir Touati II, Mohammed Elamri III, Farid Touati IV, Qatar Univ. (Qatar)

Free-Space Optics (FSO) is a wireless technology that enables the optical transmission of data though the air. FSO is emerging as a promising alternative or complementary technology to fiber optic and wireless radio-frequency (RF) links due to its high-bandwidth, robustness to EMI, and operation in unregulated spectrum. These systems are envisioned to be an essential part of future generation heterogeneous communication networks. Despite the vibrant advantages of FSO technology and the variety of its applications, its widespread adoption has been hampered by rather disappointing link reliability for long-range links due to atmospheric turbulence-induced fading and sensitivity to detrimental climate conditions. A major challenge of such systems is to provide a strong backup system with soft-switching capabilities when the FSO link becomes down. Using the same medium for backup will not help, in the case of the link cut, because most likely the same technology will be cut as well. This is the reason why we decided to create a different medium RF as a backup.

The specific objective of this work is to study for the first time in Qatar and the GCC the link capacity, link availability, and link outage of an FSO system with RF back up (i.e. hybrid FSO/RF) under harsh environment.

In order to analyze the two transport media, we have ported Embedded Linux on FPGA and designed a network sniffer application that can run into FPGA. We installed new FSO/RF terminals and configure and align them successively. In the reporting period, we carry out measurement and relate them to weather conditions. The experimental results, when compared to studies which have been carried out before in Europe and North America, show different behavior

9614-31, Session PWed

Statistical prediction of the atmospheric behavior for free space optical link

Lukas Hajek, Jan Látal, Ale? Vanderka, Andrej Liner, Stanislav Hejduk, Petr Koudelka, Vladimír Va?inek, Jan Vitasek, V?B-Technical Univ. of Ostrava (Czech Republic)

The atmosphere is unstable and unpredictable environment, where are continual changes of the air refractive index. These changes cause fluctuation of optical power at the receiver site. The prediction of behavior of the atmosphere and effect of this behavior on the FSO link is very complicated or even impossible. Aim of this article is focused to statistical analysis of measured level signal RSSI of the FSO link and atmospheric properties measured by hydro-meteorological station. For finding probability distribution function PDF of measured data the statistical analysis tools were used. Next part of article is focused on determination of the linear regression model to calculate level of RSSI depending on the atmospheric properties. Two empirical equations are result for day and night time. These equations describe behavior of signal RSSI in 30 days interval. Finally, comparison of the obtained mathematical model with real measured data of RSSI was introduced for one week before and one week after the analyzed time interval.

9614-32, Session PWed

Modulation of radio signal using laser beam

Mohammad M. Anwar, Asiatic Society of Bangladesh (Bangladesh)

Radio signal can be modulated using laser beam as career wave by converting radio frequency in to laser beam using laser beam radio frequency conversion transducer and then producing interference for getting modulated wave and transmitting through a transmitter for sending long distance transmittance q switched or pulsed laser for efficient radio communication.we will use any receiver for demodulated laser beam for getting radio wave by using another transducer that will convert laser beam to original radio frequency and transmit in the local area by amplifying signal and transmitting from laser demodulation substation that can be in fm radio signal .

9614-33, Session PWed

Performance analysis of OOK receiver with a GSM laser source in space to ground optical communication link

Mengnan Li, Liying Tan, Jing Ma, Siyuan Yu, Jiajie Wu, Qi Wang, Harbin Institute of Technology (China)

In practice, due to the laser device own reason and the inevitable error of the processing technic, the laser source emitted from the communication terminal is represented as partially coherent laser. In space to ground optical communication link, the variation of the source coherent parameter and the zenith angle has effects on the incident optical intensity at the receiver aperture. With full consideration of both the average optical intensity and scintillation, the statistical distribution of the optical intensity is given with different wavelength, beamwidth and zenith angle. The effects of the source coherent parameter on the performance of OOK receiver is systematically analyzed. The average bit error rate (BER) is obtained in the presence of the degradation of the source coherent degree. The results manifest that the performance degrades seriously with the increasing source coherent parameter or the zenith angle, while the degradation is less with a smaller wavelength or a bigger beamwidth. The work is hoped to improve the redundancy design of the optical communication receiver system.

9614-34, Session PWed

Orthogonal phase modulation with self homodyne detect laser communication method for the satellite-to-ground link

Jianfeng Sun, Peipei Hou, Xiaoping Ma, Liren Liu, Shanghai Institute of Optics and Fine Mechanics (China)

Signal laser propagation will pass through the random atmosphere turbulence channel in satellite-to-ground laser communication application. The turbulence will cause the wavefront distortion in the receiver telescope front. For direct detection laser communication system, atmospheric turbulence can affect the coupling efficiency from space laser to the detector. For coherent detection laser communication system, Atmosphere turbulence not only affects the coupling efficiency, but also can seriously reduce the heterodyne detection efficiency. Coherent detection communication receiver must use small aperture telescopes or large aperture telescope with adaptive wavefront compensation system.

To mitigate the influence of the atmosphere turbulence, we proposed a new method base orthogonal phase modulation with self homodyne detect. This method can not only mitigate the influence of the turbulence, but also adjust the communication date rate steplessly. The experiment results show that the method is very suitable to the satellite-to-ground link.

Conference 9615: Quantum Communications and Quantum Imaging XIII

SPIE. OPTICS+ PHOTONICS OPTICAL ENGINEERING+ APPLICATIONS

Recent progresses in quantum imaging real applications *(Invited Paper)*

Marco Genovese, Istituto Nazionale di Ricerca Metrologica (Italy)

Recent progresses in Quantum Imaging Real Applications

I.Ruo Bechera, A.Meda, E.Moreva, P.Traina,I.Degiovanni,G.Brida, Marco Genovese

Quantum imaging is, together with quantum key distribution, the quantum technology more mature for practical applications [1,2,3,4].

In this talk, after a general introduction to the argument, we will present two recent results achieved in INRIM laboratories paving the way for next future commercial use of these techniques.

The first exploits non-classical photon statistics of single nitrogen-vacancy color centers in diamond for realising super-resolution. A little more in detail we demonstrate that the measurement of high order correlation functions allows overcoming Abbe limit.

The second exploit ghost imaging [4] in a specific case of practical interest, i.e. in measuring magnetic structures in garnets. Since it is of large interest to perform these measurements in cryogenic regime a direct imaging is difficult. An acquisition through an optical fiber would be much simpler, but spatial resolution would be lost. The use of ghost imaging through correlated beams would permit recovering spatial information of the light that passed through the sample and the fiber.

Two-mode squeezed light source for quantum illumination and quantum imaging

Genta Masada, Tamagawa Univ. (Japan)

Quantum illumination is a recently developed target detection scheme by using quantum entanglement and expected to provide improvement in error probability for discrimination of target present or absent even in a lossy and noisy environment. The original idea was firstly proposed in the case of entangled photon pair and extended to the case of Gaussian states. We are developing high quality two-mode squeezed light as a quantum entanglement resource for exploring the possibility of quantum illumination radar system and expecting to apply to quantum imaging.

Two-mode squeezed light is a non-classical state of the electro-magnetic field and can be generated by combining two independent single-mode squeezed lights by using a beam splitter with relative phase of 90 degrees between each optical field. It shows strong correlation between quadrature phase amplitudes in each mode. In order to reveal the quadrature entanglement in the actual experiment, it is important to generate highly squeezed light.

To generate single-mode highly squeezed light, we employ a sub-threshold optical parametric oscillator (OPO) which includes a nonlinear optical crystal for the second order nonlinear interaction. Especially, we implement an OPO including a periodically polled potassium titanyl phosphatecrystal (PPKTP) with bow-tie configuration of optical cavity and create two-mode squeezed light for quantum radar such as quantum illumination and quantum imaging.

9615-4, Session 2

Quantum repeaters for long distance quantum communication *(Invited Paper)*

Liang Jiang, Sreraman Muralidharan, Linshu Li, Yale Univ. (United States); Norbert Lutkenhaus, Univ. of Waterloo (Canada); Jungsang Kim, Duke Univ. (United States); Mikhail D. Lukin, Harvard Univ. (United States)

Quantum repeaters (QRs), as a promising approach for long distance quantum communication, can overcome both loss and operation errors, and exponentially speedup the communication rate. Loss errors can be suppressed by heralded entanglement generation (HEG) or quantum error correction (QEC). Operation errors can be corrected by heralded entanglement purification (HEP) or QEC. Both HEG and HEP requires two-way classical signaling, while QEC only requires one-way communication.

Depending on the methods used to suppress loss and operation errors, we can classify various QRs into three generations. The first generation of QRs uses HEG and HEP to suppress loss and operation errors. The second generation uses HEG to suppress loss errors and QEC to correct operation errors. The third generation of QRs relies on QEC to correct both loss and operation errors.

To compare different quantum repeater protocols, we need to consider both temporal and physical resources, which are characterized by the key generation rate and the total number of qubits. By introducing the cost function to characterize both temporal and physical resources, we can systematically compare three generations of QRs for various experimental parameters, including coupling efficiency, gate fidelity, and gate times. We have identified different parameter regions with drastically different architectural designs of quantum repeaters with different possible physical implementations. This will provide a guideline for the optimal design of quantum networks over global scales.

9615-5, Session 2

An ion-cavity interface for quantum networks *(Invited Paper)*

Tracy E. Northup, Bernardo Casabone, Konstantin Friebe, Klemens Schüppert, Florian Ong, Moonjoo Lee, Dario Fioretto, Univ. of Innsbruck (Austria); Rainer Blatt, Leopold-Franzens-Univ. Innsbruck (Austria) and Institut für Quantenoptik und Quanteninformation (Austria)

Trapped ions are a promising platform for local quantum information processing, but as stationary qubits, they are not well suited for quantum communication. Optical cavities offer a coherent interface between matter and light, enabling the transfer of quantum information from stationary qubits onto photons for long-distance distribution.

We demonstrate such an interface by coupling trapped ions to a cavity and have recently shown that a quantum state can be faithfully transferred from an ion onto a photon. In particular, this transfer can be improved by taking advantage of a collective effect between multiple ions, namely, superradiant emission into the cavity. In this proof-of-principle experiment, we tune the phase of a two-ion entangled state between sub- and superradiance. The

superradiant coupling is then used to enhance the transfer of quantum information onto a photon from a logical qubit encoded in the two ions.

Finally, prospects for linking together distant ions in cavities via a quantum network will be discussed. Toward this goal, I will outline a fiber-based ion-cavity experiment which should allow access to the single-ion strong-coupling regime.

9615-6, Session 2

Narrowband correlated single photon source for quantum communications and quantum memory applications from a cavity referenced to cesium atoms *(Invited Paper)*

Oliver Slattery, Lijun Ma, Paulina Kuo, Xiao Tang, National Institute of Standards and Technology (United States)

Spontaneous parametric down conversion (SPDC) is commonly used to produce degenerate photon pairs (both photons are the same wavelength) and non-degenerate pairs (each photon are different wavelengths), naturally broadened to hundreds of gigahertz or a terahertz. For successful interaction with atomic ensembles, the interacting photon must achieve a very narrow linewidth, in the order of tens of megahertz. For long distance quantum communications, the transmitting photons must be within a telecommunications band. We describe narrowband non-degenerate SPDC sources with one photon at a telecommunications wavelength (near 1310 nm) and the second photon at a wavelength suitable for quantum memory via integration with an atomic (Cesium) ensemble. A cavity narrowed non-degenerate correlated photon pair source can interface quantum memory and quantum communications applications.

The experiment includes a non-linear periodically poled bulk crystal (lithium niobate) pumped at 532 nm and the resulting pairs of correlated photons near 895 nm and 1310 nm, respectively. The single pass (no cavity) linewidths are several nm. By introducing the crystal into a cavity and by relying on the principle of the conservation of energy in the non-linear interaction, the effect is to limit the generation of the pairs to the linewidths matching the resonant modes of the cavity. The resonating cavity is locked to the D1 transition of the Cesium atom. The resulting linewidth at exactly 894.3-nm will be significantly narrower than the single pass linewidth.

Applications include quantum repeaters and the advancement of quantum computer networks.

9615-7, Session 3

Enabling transmitter and receiver technology for free-space quantum key distribution *(Invited Paper)*

David Woolf, Joel M. Hensley, Physical Sciences Inc. (United States)

The need for unconditionally secure communication links has been growing as traditional encryption techniques become less secure due to advances in computation. Quantum Key Distribution (QKD) is an enabling framework through which secure communication can be achieved. For free-space QKD, a primary challenge exists in detecting single-photons against a sky background, particularly during the daytime. In order to do this, a spectrally narrow, on-demand, and bright single photon source must be paired with a detector capable of significant temporal, spatial and spectral filtering. Here, we report on our development of a transmitter-receiver pair consisting of a spectrally-narrow, cavity coupled diamond color center single photon source and a detector containing a two-stage atomic line filter (ALF) built from isotopically pure Rubidium (Rb) vapor cells. The emitter and receiver are capable of producing a sub-GHz spectral linewidth for emission and detection respectively, which is a 50x improvement over the current state of the art and will enable the construction of high data-rate, unconditionally secure free space data links.

9615-8, Session 3

Secure satellite communication using multi-photon tolerant quantum communication protocol

Bhagyashri A. Darunkar, Nikhil V. Punekar, Pramode K. Verma, The Univ. of Oklahoma - Tulsa (United States)

This paper proposes and analyzes the potential of a multi-photon tolerant quantum communication protocol to secure satellite communication. For securing satellite communication, quantum cryptography is the only known unconditionally secure method. A number of recent experiments have shown feasibility of satellite-aided global quantum key distribution (QKD) using different methods such as: Use of entangled photon pairs, decoy state methods, and entanglement swapping. The use of single photon in these methods restricts the distance and speed over which quantum cryptography can be applied.

Contemporary quantum cryptography protocols like the BB84 and its variants suffer from the limitation of reaching the distances of only Low Earth Orbit (LEO) at the data rates of few kilobits per second. This makes it impossible to develop a general satellite-based secure global communication network using the existing protocols. The method proposed in this paper allows secure communication at the heights of the Medium Earth Orbit (MEO) and Geosynchronous Earth Orbit (GEO) satellites. The benefits of the proposed method are two-fold: First it enables the realization of a secure global communication network based on satellites and second it provides unconditional security for satellite networks at GEO heights. The multi-photon approach discussed in this paper ameliorates the distance and speed issues associated with quantum cryptography through the use of contemporary laser communication (lasercom) devices. This approach can be seen as a step ahead towards global quantum communication.

Channel models for QKD at higher photon flux levels based on spatial entanglement of twin beams in PDC

Marina Mondin, Politecnico di Torino (Italy); Fred Daneshgaran, California State Univ., Los Angeles (United States); Ivo P. Degiovanni, Marco Genovese, Ivano Ruo Berchera, Istituto Nazionale di Ricerca Metrologica (Italy)

Twin beams generated by Parametric Down Conversion (PDC) exhibit quantum correlations that have been effectively used as a tool for many applications including calibration of single photon detectors and QKD applications [1]. Within QKD applications, the natural setup of quantization of Charge Coupled Device (CCD) detection areas and subsequent measurement of the correlation statistic needed to detect the presence of the eavesdropper Eve, leads to a set of QKD parallel channel models that are either binary or multilevel Discrete Memoryless Channels (DMC). This work explores the derivation of proper channel models for this application starting from measured data, the evaluation of the associated channel capacity, and the application of polar codes for information reconciliation over the resulting parallel DMCs.

9615-10, Session 3

A modified quantum secret sharing algorithm for distributing two-party secret keys *(Invited Paper)*

Warren P. Grice, Phil Evans, Benjamin Lawrie, Oak

Ridge National Lab. (United States); Matthieu Legre, id Quantique SA (Switzerland); Pavel Lougovski, William Ray, Brian Williams, Bing Qi, A. Matthew Smith IV, Oak Ridge National Lab. (United States)

We have developed and demonstrated a novel method for distributing random secret information based on N-party single-qubit Quantum Secret Sharing (QSS). Unlike QSS, however, our method does not require a meeting between N-1 of the participants. In addition, our method permits any two participants to establish a secure key known only to them. We have tested our new protocol with N = 3 parties on a single quantum channel using a commercial QKD system developed by ID Quantique. We demonstrate how any two out of the N participants can build a secret key by using partial information from each other and with collaboration from the remaining N ? 2 parties. We note that our protocol is generalizable to any hardware implementation. This novel protocol allows for the creation of two-party secret keys were standard QSS does not, and it significantly reduces the number of resources (single photon detectors, lasers and dark fiber connections) needed to implement single photon QKD.

9615-11, Session 4

Twin photon source: spatio-temporal properties

Joyee Ghosh, Indian Institute of Technology, Delhi (India) and ICFO-The Institute of Photonic Sciences (Spain); Gabriel Molina-Terriza, ICFO-The Institute of Photonic Sciences (Spain) and Macquarie Univ. (Australia); N. Piro, ICFO-The Institute of Photonic Sciences (Spain) and École Polytechnique Fédérale de Lausanne (Switzerland); L. Dubreuil, Juan P. Torres, ICFO-The Institute of Photonic Sciences (Spain); Juergen Eschner, ICFO-The Institute of Photonic Sciences (Spain) and Univ. des Saarlandes (Germany)

We propose a method to study the spatio-temporal properties of degenerate photon pairs emitted in SPDC, using temperature variation. The photons can be distinguished. We relate these to the measured Hong-Ou-Mandel dip of the photons.

9615-12, Session 4

EIT quantum memory based on Cs Atom *(Invited Paper)*

Lijun Ma, Oliver Slattery, Paulina Kuo, Xiao Tang, National Institute of Standards and Technology (United States)

Quantum memory is an important device to realize long distance quantum communication and linear quantum computing. Quantum memory based on Electromagnetically-induced transparency (EIT) is one of most promising approaches to implement such device.

EIT is a nonlinear optical phenomenon in atoms with a ? energy level structure. In this energy structure, a signal field carries the quantum information while another strong coupling field is used to control the atomic system. The two fields couple excited level to their respective ground levels, and can store and retrieve a pulse of light. The kind of storage/retrieval process is known to be able to preserve certain quantum properties of the light. The memory media can be either warm vapor or cold trapped atoms.

Currently, most work on the EIT based quantum memory use Rb atoms. However, the transition wavelengths of Cs are suitable for quantum communication systems. The 852 nm Cs transition corresponds to the wavelength of the first generation optical communication systems, while the 895 nm Cs transition wavelength, corresponds to a popular photon pair (895+1310 nm) generated by spontaneous parametric down conversion with 532 nm pump wavelength. EIT quantum memory with Cs atoms would have many potential applications in quantum communication systems.

We will present our work on EIT quantum memory with both warm vapor and trapped cold Cs atoms, and characterize their performance.

9615-13, Session 4

Hybrid quantum photonic applications of nanodiamond

Brant C. Gibson, RMIT Univ. (Australia)

The approach for combining NV quantum emitters [1,2] with photonic structures has been developed by embedding NDs into tellurite (TZN) glass, which is then drawn into fiber. This approach allows improved efficiency of the NV emitter to be coupled to a bound mode in the fiber [3] and significantly enhances device robustness. Tellurite glass was selected as the host material as it is liquid at relatively low temperatures (600-700 deg C), which minimizes ND oxidation while enabling the NDs to be mixed into the glass melt [4]. Tellurite glasses transmit light in the NV center excitation and emission wavelength range (500-800 nm), and have a high refractive index (n=2.0), which enhances the capture of the NV emission in the fiber core. In this work, the origin of loss in ND-doped tellurite glass was explored [5]. Based on this understanding, the loss of ND-doped tellurite fibers was reduced by more than an order of magnitude down to 10 dB/m across the 600-800 nm wavelength range while preserving functional NDs in the glass [6]. Using optimal fabrication conditions, future fibers with low loss and active, embedded NDs will be used to investigate single photon emission and propagation of quantum information along the fibers, which have the potential to become the photonic backbones for quantum applications.

New opportunities for quantum storage in diamond *(Invited Paper)*

Philip R. Hemmer, Texas A&M Univ. (United States)

Nitrogen-vacancy (NV) color centers in diamond have shown great promise for quantum information applications. However the NV has limitations that have slowed the development of quantum repeaters. For this reason, other solid-state emitters have been explored recently such as rare earth doped crystals and color centers in diamond like the silicon-vacancy (SiV). In this talk I will review the recent work on coherent population trapping (CPT) in SiV and discuss the advantages and dis-advantages compared to the NV for quantum storage applications.

9615-15, Session 5

Quantum vacuum emission from a moving refractive index front *(Invited Paper)*

Maxime Jacquet, Friedrich Koenig, Univ. of St. Andrews (United Kingdom)

A thermal flux of light is constantly emitted from the quantum vacuum at the horizon of black holes [1]; sadly it is too feeble to ever be detected. However, it is possible to create optical analogues of the event horizon in which spontaneous emission of photons from the quantum vacuum can be observed [2].

We theoretically investigate the spontaneous emission of light from the

vacuum in a nonlinear dielectric modelled by two joint multi-branch dispersive media that differ in their refractive index. Our aim is to develop further an existing analytical model [3] to describe the scattering of vacuum modes at the Refractive Index Front (RIF) that separates these regions.

We show that under certain conditions, set by the velocity and height of the RIF in the dielectric, there exists a frequency window over which the scattering process resembles black hole emission: the RIF acts as a point of non-return for modes of the fields and quanta are emitted from the vacuum in a unique mode that propagates away from the RIF.

We study the properties of the eigenmodes in all different possible scattering configurations at the RIF and compute the spectra of emission from the vacuum. We investigate the influence of the RIF height and velocity in the medium on the characteristics of this emission and calculate the number of photons created from the vacuum.

A solid state spin-wave optical quantum memory

Margherita Mazzera, Mustafa Gündo?an, Patrick M. Ledingham, Kutlu Kutluer, ICFO - Institut de Ciències Fotòniques (Spain); Hugues de Riedmatten, ICFO - Institut de Ciències Fotòniques (Spain) and Institució Catalana de Recerca i Estudis Avançats (Spain)

Rare earth doped crystals (REC) are promising candidates as quantum memories as they offer coherence properties comparable to atomic systems, but free of the drawbacks deriving from the atomic motion. The research on REC quantum memories has been so far mostly focused on the mapping of quantum bits to optical collective excitations. However, this leads to short lived and mostly pre-determined storage. We report here on the spin-wave storage and on-demand retrieval of weak coherent states of light at the single-photon level in a Pr3+ doped Y2SiO5 crystal. The storage protocol employed is the atomic frequency comb scheme, which relies on the creation of a periodic absorption structure within the inhomogeneously broadened transition of Pr3+ at 606 nm. In order to suppress the noise created by the control pulses, we employ different filtering stages, including spatial, temporal and narrow-band spectral filtering. The latter is implemented by burning a spectral hole in a second Pr3+: Y2SiO5 crystal. Adopting this strategy we achieve a signal-to-noise ratio > 10 for single-photon-level weak coherent pulses. Furthermore we demonstrate the coherent storage and on-demand read-out of time-bin qubits containing less than one photon per pulse with conditional fidelities (i.e. assuming that a photon is reemitted) larger than the classical threshold, taking into account the Poissonian statistics of the input fields and the finite memory efficiency. These results are promising in view of the spin-wave storage of quantum states of light and of the use of solid state memories in quantum repeater architectures.

9615-17, Session 5

Quantum nonlinear optics with optical nanofibers

Daniel E. Jones, James D. Franson, Todd B. Pittman, Univ. of Maryland, Baltimore County (United States)

Single-photon nonlinearities are useful for quantum computation, quantum communications, and quantum information processing. Optical nonlinearities have been demonstrated at the single-photon level using systems such as Rydberg Blockades, cavity QED, etc; however, more robust, single-pass experiments are also desirable. Examples of such systems include hollow-core fibers filled with atomic vapors and sub-wavelength diameter tapered optical nanofibers surrounded by atomic vapors. The underlying principle of such systems is the confinement of the optical mode to very small cross-sectional areas over very long distances. This allows the realization of very high intensities and nonlinearities at ultra-low powers approaching the single-photon level.

In this talk, we will review our recent work with tapered optical nanofibers in rubidium vapor, including demonstrations of saturated absorption, two-photon absorption, and electromagnetically induced transparency (EIT) at ultralow (~nW) power levels. The ability to achieve these nonlinear processes at such low powers is promising for the use of optical nanofibers for quantum information processing with single photons and/or weak coherent states.

9615-18, Session 5

Single “atom-like” defects in silicon carbide for future quantum photonics *(Invited Paper)*

Stefania Castelletto, RMIT Univ. (Australia)

Defects are common in many materials and some were regarded as detrimental. Recently with the advent of ultra-sensitive detectors, super-resolution microscopy advanced methodologies, optical single spin magnetic resonance and advanced material synthesis and doping, some of conventional semiconductors intra-band gap defects such as NV centre in diamond and their nanostructured counterpart are revealed to be a disruptive discovery for nanoscale sensing in physics, biology and quantum technology. I will present equivalent centres in a similar semiconductor, silicon carbide (SiC). SiC harbour similar defects as NV in diamond, and we have recently identified the first single photon emission in 4H-SiC attributed to a carbon-antisite vacancy pairs. I will show more recent results on single defects SiC nanoparticles, tetrapods and SiC devices providing novel information on their physics and atomistic structure. The fundamental understanding of these defects is essential for their engineering and deployment in next generation multifunctional sensors.

Boson sampling with integrated photonics

Fabio Sciarrino, Univ. degli Studi di Roma La Sapienza (Italy)

Boson Sampling is a specialized task which consists in sampling from the output distribution of a system of non-interacting bosons evolving through a linear unitary transformation. It is believed that simulating Boson Sampling experiments (even approximately) with a classical approach is computationally hard, since it requires the calculation of permanents of square matrices. This task represents a promising approach to show the computational capabilities of quantum mechanics in systems of smaller-size than an universal quantum computer, whose large-scale version is currently far with the present technology. This task is naturally solved by photons evolving through a linear optical interferometers and coincidence detection at the output. The recent progresses in photonics technology have lead to the first experimental implementations of Boson Sampling experiments in small-scale system, and to an experimental study of bunching phenomenon in multi-photon interferometers. At variance with other computational tasks, such as factoring of large integer numbers, due to its very complexity there is no-trivial way to certify the correct operation of a Boson Sampling device

where the size of the system increases. Hence it is crucial to identify suitable strategies to correctly discriminate Boson Sampling events from data sampled from other alternative distributions.

Experimental demonstration of delayed-choice decoherence suppression *(Invited Paper)*

Jong-Chan Lee, Hyang-Tag Lim, Kang-Hee Hong, Youn-Chang Jeong, Pohang Univ. of Science and Technology (Korea, Republic of); Myungshik Kim, Imperial College London (United Kingdom); Yoon-Ho Kim, Pohang Univ. of Science and Technology (Korea, Republic of)

Wheeler's delayed-choice experiment illustrates vividly that the observer plays a central role in quantum physics by demonstrating that complementarity or wave–particle duality can be enforced even after the photon has already entered the interferometer. The delayed-choice quantum eraser experiment further demonstrates that complementarity can be enforced even after detection of a quantum system, elucidating the foundational nature of complementarity in quantum physics. However, the applicability of the delayed-choice method for practical quantum information protocols continues to be an open question. Here, we introduce and experimentally demonstrate the delayed-choice decoherence suppression protocol, in which the decision to suppress decoherence on an entangled two-qubit state is delayed until after the decoherence and even after the detection of a qubit. Our result suggests a new way to tackle Markovian decoherence in a delayed manner, applicable for practical entanglement distribution over a dissipative channel.

Hong-Ou-Mandel interference for the orbital angular momentum Bell States: a high dimensional analysis

Yingwen Zhang, Filippus S. Roux, CSIR National Laser Ctr. (South Africa); Thomas Konrad, Univ. of KwaZulu-Natal (South Africa); Megan Agnew, Jonathan Leach, Heriot-Watt Univ. (United Kingdom); Andrew Forbes, CSIR National Laser Ctr. (South Africa)

Hong-Ou-Mandel (HOM) interference is a fundamental component in many quantum information protocols and one of the defining features of quantum science. Traditional HOM measurements are implemented in two-dimensional Hilbert spaces and are used to filter anti-symmetric components from an input state. Here, we are able to filter the anti-symmetric components from a high-dimensional entangled field. We use Dove prisms to control the precise form of the high-dimensional two-photon state and reveal state-specific constructive and destructive quantum interference. This work paves the way for high-dimensional processing of multi-photon quantum states, for example, in teleportation beyond qubits. Further, this work highlights the role that the symmetry of the state, rather than the distinguishability of the individual photons, plays in HOM interference

9615-23, Session 6

Quasi-Bell entangled coherent states and its quantum discrimination problem in the presence of thermal noise *(Invited Paper)*

Kentaro Kato, Tamagawa Univ. (Japan)

We are interested in whether or not entangled coherent states are applicable to quantum information-communication technologies as an information processing resource in practical situation. For this question, we discussed the effect of channel loss to the so-called quasi-Bell entangled coherent states in the context of the quantum reading scheme at the past conference (Proc.SPIE 88750P, 2013).

In this study, the effect of thermal noise to the quasi-Bell entangled coherent states is discussed. We first investigate physical properties of the quasi-Bell entangled coherent states such as the photon statistics of it, in the presence of thermal noise. Secondly a quantum discrimination problem of the quasi-Bell entangled coherent states under the influence of thermal noise is discussed in accordance with quantum signal detection theory. Then the error probability of the quantum optimum discrimination for such thermal states will be shown. Finally, we will discuss the combination of the effects from the channel loss and the thermal noise.

9615-24, Session 7

Low-power optical communication: approaching the quantum limit *(Invited Paper)*

Konrad Banaszek, Univ. of Warsaw (Poland)

We discuss selected strategies to reach the maximum transmission rate, defined by the Holevo bound, of a lossy narrowband optical channel under the constraint of a low mean photon number. When direct detection is used at the output, the ultimate capacity can be approached by optimizing pulse position modulation (PPM) encoding with respect to the symbol length. An approximate analytical formula for the PPM transmission rate is presented, which quantifies the effects of photon statistics in terms of the g(2) normalized second-order intensity correlation function of the light source. The highly imbalanced instantaneous power distribution in PPM encoding can be remedied by the use of binary phase shift keying (BPSK) employing the recently proposed collective receiver based on Hadamard words. It is shown that for collective BPSK encoding, the transmission rate in the presence of phase noise is equivalent to that of PPM with super-Poissonian light statistics, retaining enhanced scaling with the mean photon number compared to individual detection.

9615-25, Session 7

Security loopholes in a free-spece quantum communication receiver *(Invited Paper)*

Vadim Makarov, Shihan Sajeed, Poompong Chaiwongkhot, Jean-Philippe Bourgoin, Univ. of Waterloo (Canada); Thomas D. Jennewein, Univ. of Waterloo (Canada) and Canadian Institute for Advanced Research (Canada); Norbert Lütkenhaus, Univ. of Waterloo (Canada)

Quantum key distribution (QKD) is perfectly secure in theory, however practical implementations are challenging and harbor physical imperfections that open up security loopholes. Free-space QKD can be used to communicate between earth-based stations, ships, aircrafts, or a satellite. The latter allows to make a global QKD network using the satellite as a trusted relay between a network of ground stations. In free-space QKD, a four-state polarization analyser is commonly used at the receiver station. We study imperfections of this complex optical component that may open

security loopholes. One dangerous imperfection is that the sensitivity of receiver's detectors depends differently on the spatial mode of incoming photons. Consequently, an attacker can control the spatial mode to break security. We identify experimentally the sources of efficiency mismatch in the optical scheme. We then model a practical intercept-and-resend attack and show that it would break security in most situations. We show experimentally that adding a spatial filter at the receiver's entrance is an effective countermeasure. However we subsequently demonstrate a counter-attack to this countermeasure. Other types of imperfections also exist in this type of QKD receiver.

Experimental investigation on local environment effects on the quantum teleportation fidelity *(Invited Paper)*

Laura T. Knoll, Instituto de Investigaciones Científicas y Técnicas para la Defensa (Argentina); Christian T. Schmiegelow, UNIDEF (CITEDEF-CONICET) (Argentina); Miguel A. Larotonda, Instituto de Investigaciones Científicas y Técnicas para la Defensa (Argentina)

Quantum teleportation relies on entanglement as the quantum resource to be able to communicate with fidelities beyond the classical limit. Nevertheless, the entangled resource may be afflicted by local noise, affecting it's ability to serve as the entangled resource for quantum teleportation. We obtain experimental data on the influence of different local environments on the ability of an initially entangled pair of qubits to act as a teleportation resource after it has been afflicted by noise.

We access to selected conditions on the noise parameter space, both theoretically and experimentally, where an already noisy protocol can be made practically insensitive to a further addition of noise. The experimental results are based on a photonic implementation of the quantum teleportation algorithm, with a polarization-entangled pair acting as the quantum resource. The state to be teleported is an additional qubit encoded in the path internal degree of freedom of Alice's photon. Interactions with different local environments on both sides of the system are either implemented with an extra qubit as the environment, or simulated as a weighed average of pure states.

We compare our experimental results with the theoretical predictions, and by performing quantum process tomography we can calculate the fidelity of the quantum teleportation scheme and evaluate the effect of local environments.

9615-28, Session 8

Deploying quantum light sources on nanosatellites: lessons and perspectives

Alexander Ling, National Univ. of Singapore (Singapore)

The Small Photon Entangling Quantum System (SPEQS) is an integrated entangled photon system where the pump, photon pair source (based on SPDC) and detectors are combined within a single optical tray and electronics package that is no larger than 10 cm x 10 cm x 3 cm. This footprint enables the SPEQS instrument to be placed onboard nanosatellites or the CubeLab structure aboard the International Space Station. The purpose of the SPEQS instrument is to understand the different environmental conditions that may affect the operation of an entangled photon source in low earth orbit. This understanding is crucial for the construction of cost-effective entanglement distribution or QKD type experiments that utilize nanosatellite architecture and compact entangled photon systems. We will discuss the challenges, lessons we have learned over 3 years of development and testing and also the perspectives for future advanced experiments.

9615-29, Session 8

Photonic quantum computing

Jeremy L. O'Brien, Univ. of Bristol (United Kingdom)

Of the various approaches to quantum computing, photons are appealing for their low-noise properties and ease of manipulation at the single qubit level; while the challenge of entangling interactions between photons can be met via measurement induced non-linearities. However, the real excitement with this architecture is the promise of ultimate manufacturability: All of the components---inc. sources, detectors, filters, switches, delay lines---have been implemented on chip, and increasingly sophisticated integration of these components is being achieved. We will discuss the opportunities and challenges of a fully integrated photonic quantum computer.

Twin photons: spatial and temporal properties by coincidence detection

Joyee Ghosh, Indian Institute of Technology, Delhi (India)

Narrowband entangled photon pair sources based on spontaneous parametric down-conversion are an important tool in many quantum information processing applications. The thorough characterization of the spatio-temporal properties of the emitted photon pairs is crucial to establish their full control. In this paper we show a method to characterize the spatial and temporal properties of these photons using a filtering system combined with temperature scanning of the nonlinear crystal. We then relate the measured spatio-temporal properties to the measured Hong-Ou-Mandel interference dip of the paired photons, measured in a parallel experiment. By studying the spatio-temporal properties of the generated photons, we show, in particular, that the emitted photons can be distinguished due to their different spectra.

9615-32, Session PWed

Quantum repeater research at NIST

Xiao Tang, Oliver Slattery, Lijun Ma, Paulina Kuo, Alan Mink, National Institute of Standards and Technology (United States)

Quantum repeaters are indispensable modules for connecting distributed quantum systems to form a scalable architecture for an entanglement-based distributed quantum network. Recognizing that distributing, maintaining, and utilizing quantum entanglement is foundational to any quantum network and the necessary building blocks that must be implemented in a quantum repeater. The main critical technical challenges for realization of a quantum repeater include high-efficiency coupling between flying qbits

and stationary qbits, quantum memory with high efficiency, high fidelity and long storage time, and quantum teleportation/Bell state measurement with high visibility.

To overcome these challenges, the NIST quantum communication team has focused on the development of the required building blocks for the realization of quantum repeaters as following:

1. Active quantum interface: for generating non-degenerated entangled photon pairs, in which one photon is at a telecom wavelength and the other is at a desired atomic transition line with narrowed linewidth and stabilized frequency.

2. Passive quantum interface: for converting existing single photons at the telecom wavelengths to a desired atomic transition line, or vice versa.

3. Photon pair sources based on four-wave mixing (FWM) in micro silica toroid: for generating narrowband photon pairs directly placed at a desired atomic transition line.

4. Photon interference studies: to prepare for Bell state measurements, and quantum teleportation.

5. Quantum memory: newly launched research based on Cs warm cells and cold atomic ensembles.

6. Quantum error correction and post processing algorithms.

An overview of the research efforts for quantum repeaters and networks at NIST will be presented.

9615-33, Session PWed

Preparation and characterization of optically transparent and photoluminescent electrospun nanofiber composed of carbon quantum dots and poly(acrylonitrile) blend with poly(acrylic acid)

Hak Yong Kim, Chonbuk National Univ. (Korea, Republic of)

Electrospun PAN/PAA/CQDs(poly(acrylonitrile)/ poly(acrylic acid)/ Carbon Quantum Dots composite NFs were successfully prepared by incorporating CQDs in the pre-electrospinning PAN/PAA polymer solution. It was demonstrated that CQDs were uniformly distributed inside the polymer matrix without sacrificing their optical properties as well as without disturbing the morphology of NFs too. Therefore, CQDs were found to successful conversion of NFs from non-luminescent state to multicolor emission to display blue, green and red color upon excitation by different excitation energy. These results will lead to develop a new family of advanced product of carbon based QDs and polymer such as anti-counterfeiting, UV protector, multi-functional textile, optoelectronic devices, biological labeling, and damage detection for composite structures. The composite NFs have also exhibited some UV absorption capability through compromisation of optical transparency. This property has enabled the composite to function as UV shielding material through further research.

9616-1, Session 1

Stand-off molecular composition analysis *(Invited Paper)*

Gary B. Hughes, California Polytechnic State Univ., San Luis Obispo (United States); Philip M. Lubin, Peter Meinhold, Univ. of California, Santa Barbara (United States); Hugh O'Neill, Ventura College (United States); Travis Brashears, Qicheng Zhang, Janelle A. Griswold, Jordan C. Riley, Caio Motta, Univ. of California, Santa Barbara (United States)

Molecular composition of distant stars is explored by observing absorption spectra. The star produces blackbody radiation that passes through the molecular cloud of vaporized material surrounding the star. Characteristic absorption lines are discernible with a spectrometer, and molecular composition is investigated by comparing spectral observations with known material profiles. Most objects in the solar system—asteroids, comets, planets, moons—are too cold to be interrogated in this manner. Molecular clouds around cold objects consist primarily of volatiles, so bulk composition cannot be probed. Additionally, low volatile density does not produce discernible absorption lines in the faint signal generated by low blackbody temperatures. This paper describes a system for probing the molecular composition of cold solar system targets from a distant vantage. The concept utilizes a directed energy beam to melt and vaporize a spot on a distant target, such as from a spacecraft orbiting the object. With sufficient flux (~10 MW/m2), the spot temperature rises rapidly (to ~2,500 K), and evaporation of all materials on the target surface occurs. The melted spot creates a high-temperature blackbody source, and ejected material creates a molecular plume in front of the spot. Bulk composition is investigated by using a spectrometer to view the heated spot through the ejected material. Spatial composition maps could be created by scanning the surface. Applying the beam to a single spot continuously produces a borehole, and shallow sub-surface composition profiling is also possible. Initial simulations of absorption profiles with laser heating show great promise for molecular composition analysis.

9616-2, Session 1

Orbital simulations on the deflection of near earth asteroids by directed energy *(Invited Paper)*

Qicheng Zhang, Univ. of California, Santa Barbara (United States); Kevin J. Walsh, Southwest Research Institute (United States); Carl Melis, Univ. of California, San Diego (United States); Gary B. Hughes, California Polytechnic State Univ., San Luis Obispo (United States); Philip M. Lubin, Univ. of California, Santa Barbara (United States)

Laser ablation of an asteroid on a collision course with Earth produces a cloud of ejecta which exerts a thrust on the asteroid, deflecting it from its original trajectory. The DE-STAR system provides such a thrust by illuminating an Earth-targeting asteroid from afar with a "stand-off" system consisting of a large phased-array laser in Earth orbit. A much smaller version of the same system called DE-STARLITE travel alongside the target, operating in a "stand-on" mode, slowly deflecting it over a long period of time. Such a stand-on system would also permit directing the thrust in any desired direction through careful positioning of the laser relative to the asteroid. We present orbital simulations comparing the effectiveness of both systems across a range of laser and asteroid parameters. Simulated parameters include magnitude, duration and, for the stand-on system, direction of the thrust, as well as the size and orbital characteristics of the target asteroid. These simulations indicate that deflection distance is, in general, proportional to the magnitude of thrust, proportional to the square of the laser on time, and inversely proportional to the mass. Furthermore, deflection distance shows strong dependence on thrust direction with optimal direction varying with the the asteroid's orbital eccentricity. As one example, we consider a 325 m asteroid in an orbit of eccentricity e=0.2; given 15 years of warning, a force of just 2 N from a stand-on DE-STARLITE system is sufficient to deflect the asteroid by 2 Earth radii. We discuss numerous scenarios and discuss a practical implementation of such a system consistent with current launch vehicle capability.

9616-3, Session 1

Directed energy deflection laboratory measurements *(Invited Paper)*

Travis R. Brashears, Phillip M. Lubin, Univ. of California, Santa Barbara (United States); Gary B. Hughes, California Polytechnic State Univ., San Luis Obispo (United States); Jonathan Y. Suen, Peter Meinhold, Caio A. Motta, Janelle A. Griswold, Qicheng Zhang, Miikka Kangas, Payton Batliner, Alexander A. Lang, Jordan C. Riley, Alex McDaniel, Univ. of California, Santa Barbara (United States)

Laboratory studies of the effectiveness of directed energy planetary defense as a part of the DE-STAR (Directed Energy System for Targeting of Asteroids and exploRation) program are presented. Directed energy "stand-off" and "stand-on" systems are proposed that consist of a modular array of kilowatt-class lasers powered by photovoltaics, and are capable of heating a spot on the surface of an asteroid to the point of vaporization. Mass ejection, as a plume of evaporated material, creates a reactionary thrust capable of diverting the asteroid's orbit. In a series of papers, a theoretical basis for asteroid diversion has been developed and numerical simulations have been performed to investigate the thrust produced by material evaporating from the surface of an asteroid. In the DE-STAR concept, the asteroid itself is used as the deflection "propellant". This study presents results of experiments designed to measure the thrust created by evaporation from a laser directed energy spot. A vacuum chamber was constructed to simulate space conditions, and a torsion balance that holds an "asteroid" sample was installed. The sample is illuminated with a fiber array laser with flux levels up to 60 MW/m2 which simulated a mission-level flux. The measured thrust is compared to our model results. We discuss scaling issues associated with small-scale laboratory testing vs. full-scale missions.

9616-4, Session 1

Simulations of directed energy thrust on rotating asteroids

Janelle A. Griswold, Isabella Johansson, Philip M. Lubin, Univ. of California, Santa Barbara (United States); Gary B. Hughes, California Polytechnic State Univ., San Luis Obispo (United States); Hugh O'Neill, Ventura College (United States); Peter Meinhold, Jonathan Y. Suen, Jordan C. Riley, Caio A. Motta, Qicheng Zhang, Travis R. Brashears, Univ. of California, Santa Barbara (United States)

Asteroids that threaten Earth could be deflected from their orbits using directed energy to vaporize the surface; the ejected plume creates a reaction thrust that alters the asteroid's orbit. One concern regarding directed energy deflection is the rotation of the asteroid as this will reduce the average thrust magnitude and modify the thrust direction. Flux levels required to evaporate surface material depend on surface material composition and albedo, thermal and bulk mechanical properties of the asteroid, and rotation rate. The observed distribution of asteroid rotation rates is used, along with an estimated range of material and mechanical

properties, as input to a 3D thermal-physical model to calculate the resultant thrust vector. The model uses a directed energy beam striking the surface of a rotating sphere with specified material properties, beam profile and rotation rate. The model calculates thermal changes in the sphere, including vaporization and mass ejection of the target material. The amount of vaporization is used to determine a thrust magnitude that is normal to the surface at each point on the sphere. As the object rotates beneath the beam, vaporization decreases as the temperature drops and causes both a phase shift and magnitude decrease in the average thrust vector. A surface integral is calculated to determine the thrust vector, at each point in time, producing a 4D analytical model of the expected thrust profile for rotating objects.

9616-5, Session 2

Local phase control for a planar array of fiber laser amplifiers *(Invited Paper)*

Patrick Steffanic, Benjamin T. Johannes, Gary B. Hughes, California Polytechnic State Univ., San Luis Obispo (United States); Philip M. Lubin, Peter Meinhold, Jonathan Y. Suen, Univ. of California, Santa Barbara (United States); Hugh O'Neill, Ventura College (United States); Miikka Kangas, Travis R. Brashears, Qicheng Zhang, Janelle A. Griswold, Jordan C. Riley, Caio A. Motta, Univ. of California, Santa Barbara (United States)

Arrays of phase-locked lasers have been developed for numerous directed-energy applications. Phased-array designs are capable of producing higher beam intensity than similar sized multi-beam emitters, and also allow beam steering and beam profile manipulation. In phased-array designs, individual emitter phases must be controllable, based on suitable feedback. Most current control schemes rely on feedback from the target: phases of individual emitters are adjusted to maximize flux, determined by sensing the target surface temperature. Such power-return schemes have limited scalability for target distance, number of emitters and feedback response time. This paper describes a design and control scheme that relies only on feedback from the array structure itself. A scalable geometry is based on individual hexagonal frames for each emitter; each frame cell consists of a conventional lens mounted in front of the fiber tip. A rigid phase tap structure is placed across two adjacent lenses, and physically connects the two emitter frame cells. The tap senses the exit phase of both emitters, providing information to the phase controller. The phase tap structures also include capacitive proximity sensors that measure the relative position of the tap and lens surfaces. Relative local position data, in combination with theoretical vibration modes of the compound mechanical structure, allows accurate prediction of the relative global position of emitters across the array, providing additional constraints to the phase controller. For target acquisition, infrared sensors occupy some frame cells instead of emitters. The approach is scalable for target distance and number of emitters without loss of control.

9616-6, Session 2

Orbital simulations of laser-propelled spacecraft

Qicheng Zhang, Univ. of California, Santa Barbara (United States); Kevin J. Walsh, Southwest Research Institute (United States); Carl Melis, Univ. of California, San Diego (United States); Gary B. Hughes, California Polytechnic State Univ., San Luis Obispo (United States); Philip M. Lubin, Univ. of California, Santa Barbara (United States)

Spacecraft accelerate by directing propellant in the opposite direction. In the traditional approach, the propellant is carried on board in the form of material fuel. This approach has the drawback of being limited in Delta v by the amount of fuel launched with the craft, a limit that does not scale well to high Delta v due to the massive nature of the fuel. Directed energy photon propulsion solves this problem by eliminating the need for on-board fuel storage. We discuss our system which uses a phased array of lasers to propel the spacecraft which thus contributes no mass to the spacecraft beyond that of the reflector, enabling a prolonged acceleration and much higher final speeds. This paper compares the effectiveness of such a system for propelling spacecraft into interplanetary and interstellar space across various laser and sail configurations. Simulated parameters include laser power, optics size and orbit as well as payload mass, reflector size and the trajectory of the spacecraft. As one example, a 50 GW laser with 10 km optics could propel a 1 kg craft past Neptune (~30 au) in 5 days at 4% the speed of light, or a 1 g "wafer-sat" past Mars (~0.5 au) in 20 minutes at 25% the speed of light. However, even lasers down to 10 kW power and 1 m optics show noticeable effect on gram-class payloads, boosting their altitude in low-Earth orbits by several kilometers per day.

9616-7, Session 2

Directed energy propulsion of wafer scale spacecraft for interstellar missions

Travis R. Brashears, Philip M. Lubin, Univ. of California, Santa Barbara (United States); Gary B. Hughes, California Polytechnic State Univ., San Luis Obispo (United States); Caio A. Motta, Kyle McDonough, Sebastian Roland, Alexander A. Lang, Qicheng Zhang, Univ. of California, Santa Barbara (United States)

In the nearly 60 years of spaceflight, we have accomplished incredible feats of exploration but we have barely left the solar system with Voyager achieving 17 km/s or 0.006% c in 38 years. As remarkable as this is, we will never reach even the nearest stars with our current propulsion technology. We have to radically rethink our strategy or give up our dreams of reaching the stars. We discuss an approach using directed energy to propel small wafer scale spacecraft to relativistic speeds to allow for the first interstellar missions. The technology is both modular and scalable, allowing a roadmap that starts with modest directed energy systems and builds to full interstellar capability. This offers a range of missions both interplanetary and leading to interstellar. The directed energy drive system is provided by a phased array of lasers while the spacecraft uses a radical departure from conventional designs and places a complete mission on a wafer including, power from an embedded radio nuclear thermal generator (RTG), PV, laser communications, imaging, photon thrusters for attitude control and other sensors. As one example, a future 50 GW laser array consisting of 1 - 10 kw meter scale sub elements with a 10km baseline can propel a wafer scale spacecraft with a 1m laser sail to about 26% the speed of light in about 10 minutes, reach Mars in 30 minutes, pass Voyager I in days, and reach Alpha Centauri in about 15 years. No other known technology offer this possibility.

9616-8, Session 2

Solar lens mission concept with directed energy propulsion

Travis R. Brashears, Philip M. Lubin, Univ. of California, Santa Barbara (United States)

We describe a mission concept to get to use our Sun as a gravitational lens, starting at a distance of about at 550AU, to image with extremely high angular resolution. In theory using the gravitational lens of the Sun will allow sub nano radian resolution. The concept uses an orbital phased-array laser powered by solar PV , as a directed energy photon drive to propel low-mass wafer scale spacecraft.. With recent photonic advances a complete mission can be placed on a wafer including, powered from an embedded radio nuclear thermal generator (RTG) or laser driven PV, laser communications, imaging, photon thrusters for attitude control and many other sensors. As one example, a future 200 MW laser array consisting of 1 - 10 kw meter scale sub elements with a 100m baseline can propel a 10 gram wafer scale spacecraft with a 3m laser sail at 60AU/year allowing a mission to the solar lens in about a decade of flight. Directed energy propulsion of low-mass

spacecraft gives us an opportunity to explore far outside our solar system and offers a scalable solution to even larger systems for interstellar flight. This system offers a very large range of missions from wafer scale payload launches of about 10 per day to kg scale payloads at 1 per day at 13 AU/ year.

9616-9, Session 3

Fiber Bragg gratings in microstructured optical fibers: fabrication challenges and applications *(Invited Paper)*

Francis Berghmans, Thomas Geernaert, Tigran Baghdasaryan, Hugo Thienpont, Vrije Univ. Brussel (Belgium)

The turn of the 21st century has marked the introduction of a new type of optical fiber technology that relies on so called 'microstructured optical fibers' (MOFs). Such fibers are optical waveguides formed with an array of air holes that run along the entire fiber length. MOFs exhibit unprecedented design flexibility when compared to conventional optical fibers and their properties can be tailored to answer specific application requirements. This has led to the development of supercontinuum sources, high power short pulsed fiber lasers and new fiber based optical sensors. A current hot topic in optical fiber technology research is the development of all-MOF based devices, including for example MOF based lasers and MOF based sensors. To do so one is currently investigating the combination of fiber Bragg grating (FBG) technology with MOF technology. Fabricating FBGs inside MOFs has proven not to be straightforward. The holey structure in the cladding of the MOF appears to be a spoilsport for laser based photo-inscription, as it prevents the laser radiation to reach the fiber core in an adequate manner. The intention of this paper is to review sensor applications of microstructured optical fiber Bragg gratings and to take a look at various possibilities for improving the fabrication of FBGs in MOFs with emphasis on IR femtosecond pulse laser photo-inscription methods.

9616-10, Session 4

Effects of degradation on the performance of a triphenylene based liquid crystal organic semiconductor *(Invited Paper)*

Nathan J. Dawson, Michael S. Patrick, Kyle Peters, Kenneth D. Singer, Case Western Reserve Univ. (United States); Sanjoy Paul, Brett Ellman, Kent State Univ. (United States); Rachael Matthews, Emily Pentzer, Case Western Reserve Univ. (United States); Robert J. Twieg, Kent State Univ. (United States)

We report on the effects of degradation on the charge transport properties of a discotic liquid crystal organic semiconductor, hexapentyloxyltriphenylene (HAT5). Time-of-Flight (TOF) measurements are performed in the hexagonal ordered columnar mesophase, where pristine samples show nearly nondispersive transport due to the quasi-one-dimensional transport in this mesophase. We observe how the transient properties change in samples aged over a decade. These aged samples trap charges near the interfaces in TOF cells and show greater signs of dispersive transport. These transient features are used to characterize the interfacial traps and bulk transport properties, where we use a simple model to exactly reproduce the transient behavior for a wide range of sample degradation.

It is shown that only a small amount of impurity is required for interfacial trapping. Experiments show that the interfacial trapping depends greatly on the pump wavelength with respect to the absorption curve, which confirms that the interfacial traps have microscopic length inside the HAT5. Pulse delay experiments show that ion build-up at the interface is not responsible for the creation of traps. The degradation is not found to be oxidation related, where absorbance and mass spectrometry measurements confirm a different route of degradation for the current set of aged material. We further discuss the properties of HAT5 exposed to either ozone or moisture, and we discuss future plans to study the effects of radiation and further exposure to ozone on the transport properties of organic semiconducting materials.

9616-11, Session 4

Impact of ionizing radiation on organic photovoltaic cells

Camron G. Kouhestani, Team Technologies, Inc. (United States); Roderick A. B. Devine, Team Technologies. Inc. (United States); Kenneth E. Kambour, Leidos (United States); Duc D. Nguyen, COSMIAC (United States); Gang Li, Yang Yang, Univ. of California, Los Angeles (United States); Yue Wu, Solarmer Energy, Inc. (United States)

Organic semiconductor based photovoltaic (OPV) cells potentially offer significant advantages over classical inorganic semiconductor based cells for some space based applications; specifically where criteria such as weight, flexibility and conformity are concerned. Applications in areas such as space technology represent a potential niche market where OPVs may be competitive to inorganic solar cells even though they have lower power conversion efficiencies. An example is cube satellites where power requirements are in the 10's of watts. Our particular interest, then, concerns the applicability of organic photo-cells for use in space based solar panels. It must be recognized that "unusual" conditions will exist (such as ionizing radiation, extremes of thermal cycling, etc.) – such issues are not generally addressed by the organic photo-cell community.

We have examined ionizing radiation effects in two organic photovoltaic materials for total accumulated doses up to 300 krads(SiO2). We find that the primary effect of irradiation on the characteristics of the archetypical material P3HT:PCBM characteristics is to decrease the apparent open circuit voltage, Voc, whereas in the material CS-9:PCBM, we found that the Voc increases with the accumulation of radiation. We have also compared the relaxation time during the accumulation of radiation between the two materials and found that the P3HT material remained constant, but the CS-9 material followed the Voc trend. These effects are explored in the following report. Los Angeles

9616-12, Session 4

Using complementary tools to characterize the effects of radiation in electro-optic polymeric materials *(Invited Paper)*

Javier Perez-Moreno, Skidmore College (United States)

Understanding the fundamental mechanisms behind the radiation resistance of polymers and molecules would allow us to taylor new materials with enhanced performance in space and adverse environments. Previous studies of the radiation effects on polymer-based photonic materials indicate that they are very dependent on the choice of polymer-host and guest-chromophores. The best results have been reported from the combination of CLD1 as a guest-chromophore doped in APC as host polymer, where improvement of the performance was observed upon gamma-irradiation at moderate doses. In this paper, we report on the different complementary tools that have been tried to characterize the origin of such enhancement: characterization of the nonlinear responses (SHG and electro optic), characterization of chemical properties, and application of an all-optical protocol. We derive some general conclusions by contrasting the results of each characterization, and propose complementary experiments based on microscopy techniques.

9616-13, Session 5

Proton irradiation of MWIR HgCdTe/CdZnTe

Stephen Fahey, Silviu Velicu, Ramana Bommena, Jun Zhao, EPIR Technologies, Inc. (United States); Vincent M. Cowan, Christian P. Morath, Air Force Research Lab. (United States); Sivalingam Sivananthan, EPIR Technologies, Inc. (United States)

High performance infrared sensors are vulnerable to slight changes in defect densities and locations. For example in a space application where such sensors are exposed to proton irradiation capable of generating point defects the sensors are known to suffer significant performance degradation. The degradation can generally be observed in terms of dark current density and quantum efficiency degradations. Here we report results of MWIR HgCdTe/CdZnTe single element diodes dark current densities and quantum efficiencies before and after exposure to a beam of 63MeV protons at room temperature to a total ionizing dose of 100krad(Si). We find the irradiated diodes show some signs of damage in dark current and quantum efficiency (QE). We see the performance change for individual devices, the development of a bias-dependent quantum efficiency (QE), and dark currents with different qualitative shape after dosing, as well as changes in the dark current density histogram shape for a small number of diodes.

9616-14, Session 5

MWIR unipolar barrier photodetectors based on strained layer superlattices

David A. Ramirez, Stephen A. Myers, Elena Plis, SKINfrared LLC (United States); Christian P. Morath, Vincent M. Cowan, Air Force Research Lab. (United States); Sanjay Krishna, The Univ. of New Mexico (United States)

In this work, we report on the design, growth, and fabrication of MWIR photodetectors based on InAs/GaSb Type-II superlattice. We have designed, grown, and fabricated band-structure engineered MWIR photodetectors based on the pBiBn and pBn architectures. The devices have been characterized using the most relevant radiometric figures of merits. In addition, we have characterized the degradation of the performance of the devices after exposing the devices to 63 MeV proton radiation to a total ionizing dose of 100 kRads (Si).

9616-15, Session 5

Empirical trends of minority carrier recombination lifetime vs proton radiation for rad-hard IR detector materials

Geoffrey Jenkins, Air Force Research Lab. (United States)

The continuous effort to improve space-based infrared (IR) detectors has led to a search for greater fundamental understanding of radiation damage phenomena on key material properties. The material parameter of interest in this paper is the minority carrier recombination lifetime (MCRL), which is directly related to detector performance and can be empirically determined. As radiation damage is incurred upon a detector structure, the MCRL can be significantly affected, and tracking this in a step-wise, in-situ fashion at a radiation source can reveal rates of defect introduction. This has been accomplished by the development of a portable MCRL measurement system employing time resolved photoluminescence (TRPL) while maintaining operational temperatures. Using this methodology is more insightful than the so-called 'bag tests' due to complex parameter changes witnessed with annealing as temperatures change. In addition to the system description, MCRL data on IR detectors from its inaugural deployment at a proton radiation source are analyzed and reveal a linear relationship between inverse MCRL and proton fluence.

9616-16, Session 5

Low-frequency, noise spectrum measurements of mid-wave infrared nBn detectors with superlattice absorbers

Eli Garduno, Christian P. Morath, Vicent M. Cowan, Air Force Research Lab. (United States)

Type-II Strained Layer Superlattice (T2SLS) infrared photodetectors have been in ongoing development over the last decade with the goal of achieving lower dark currents and higher operating temperatures when compared to mercury cadmium telluride (MCT). The theoretically longer Auger recombination lifetime of T2SLS has potential to lower dark current, but the presence of Shockley-Read-Hall defects limits the recombination lifetime far below the Auger-limit. In order to reduce SRH-recombination, unipolar barriers have been incorporated into the energy bands of T2SLS materials in different forms, such as nBn, to improve performance. Here, noise spectra are presented for varyingly sized, near 90% quantum efficiency, nBn mid-wave infrared (MWIR) detectors with superlattice absorbing layers grown by MBE. Noise spectrum measurements are used to evaluate device performance and reveal mechanisms contributing to low frequency noise that often exceeds predictions based on ideal shot noise. Voltage and temperature dependent noise spectra were taken using an external trans-impedance amplifier combined with an internal, cooled impedance converter and feedback resistor.

9616-17, Session 5

InAs/GaSb type II strained-layer superlattice (T2SLS) vertical transport and radiation tolerance

Mitch C. Malone, The Univ. of New Mexico (United States) and Air Force Research Lab. (United States); Christian P. Morath, Air Force Research Lab. (United States); Sanjay Krishna, The Univ. of New Mexico (United States)

Theoretical calculations predict InAs/GaSb Type II strained-layer superlattice (T2SLS) materials can perform comparably to state-of-the-art HgCdTe infrared (IR) detectors, making them a possible candidate for space-based IR sensing applications. However, several fundamental properties of these materials are still not fully understood, including the multi-carrier, electrical transport characteristics perpendicular to the superlattice plane and its proton radiation tolerance characteristics. Here, a preliminary study of the radiation tolerance characteristics of the vertical minority carrier electron transport in p-type InAs/GaSb T2SLS materials is presented. T2SLS materials were investigated via variable field magneto-resistance measurements before and after room temperature 63 MeV proton irradiation up to 100 kRad(Si). Transport was measured in magnetic fields up to ±9 T over a temperature range of 10-300 K. Quantitative mobility spectrum analysis (QMSA) and multi-carrier fitting routines were then employed to extract mobility, conductivity, and carrier concentrations from pre- and post-rad samples. A discussion of building a helium gas recovery system for the magnet dewar used in this study is also given.

9616-18, Session 6

High power VCSEL devices for atomic clock applications *(Invited Paper)*

Laurence S. Watkins, Jean-Francois Seurin, Chuni Ghosh, Delai Zhou, Guoyang Xu, Bing Xu, Alexander Miglo, Princeton Optronics, Inc. (United States)

We are developing VCSEL technology that can deliver >100mW in single frequency at wavelengths 780nm, 795nm and 850nm etc. Small aperture VCSELs with few mW output have found major applications in atomic clock experiments. Using an external cavity three mirror configuration we have

been able to operate larger aperture VCSELs with >70mW power in single frequency operation.

The VCSEL is mounted in a fiber pigtailed package with the external mirror mounted on a shear piezo. This VCSEL operates in single frequency and can be tuned by a combination of piezo actuator, temperature and current. Mode-hop free tuning over >30GHz frequency span has been obtained. Spectrum measurements show single frequency operation and demonstrate sidemode suppression of 50dB.

A Rb cell locker has been set up and the VCSEL locked to the Rb85 line using the DAVLL method. The short window linewidth was measured using the self-heterodyne method. Linewidths of <100kHz were obtained. A saturable absorption experiment was assembled and the stabilized VCSEL slowly scanned within the Rb85 transition with a 5 second timespan. The transmission probe measurement shows the 6 lines in the hyperfine structure. This measurement was used to determine the linewidth of ~1MHz for a 200mS time window. It also indicates the wavelength stability is <1MHz.

A fully package version of the high power VCSEL is being developed which will include a miniature version of the DAVLL locker inside the package.

9616-19, Session 6

A multi-channel tunable source for atomic sensors *(Invited Paper)*

Matthew S. Bigelow, Tony D. Roberts, Shirley McNeil, Todd Hawthorne, Philip R. Battle, AdvR, Inc. (United States)

We have designed and completed initial testing on a laser source suitable for atomic interferometry from compact, robust, integrated components. Our design is enabled by capitalizing on robust, well-commercialized, low-noise telecom components with high reliability and declining costs which will help to drive the widespread deployment of this system. The key innovation is the combination of current telecom-based fiber laser and modulator technology with periodically-poled waveguide technology to produce tunable laser light at rubidium D1 and D2 wavelengths (and expandable to other alkalis) using second harmonic generation (SHG). Unlike direct-diode sources, this source is immune to feedback at the Rb line eliminating the need for bulky high-power isolators in the system. In addition, the source has GHz-level frequency agility and in our experiments was found to only be limited by the agility of our RF generator. As a proof-of principle, the source was scanned through the Doppler-broadened Rb D2 absorption line. With this technology, multiple channels can be independently tuned to produce the fields needed for addressing atomic states in atom interferometers and clocks. Thus, this technology could be useful in the development cold-atom inertial sensors and gyroscopes.

9616-20, Session 6

Miniature atomic clock for space applications *(Invited Paper)*

Lute Maleki, OEwaves, Inc. (United States)

This paper will present a novel architecture for a high performance atomic clock based on the use of miniature optical whispering gallery mode (WGM) resonators. Following the approach of stabilizing a laser local oscillator to an optical transition in an atom or ion, as used in advanced atomic clock, a semiconductor laser is used for stabilization to the D1 line of Rb atoms, held in a small vapor cell. The laser is injection locked to a WGM resonator to reduce its linewidth. To produce the RF output of the clock, a second WGM resonator excited with a second cw semiconductor laser produces an optical frequency comb that is demodulated on a fast photodiode. Locking the resonator that generates the frequency comb to the laser stabilized to the Rb transition transfers the stability of the atomic transition to the RF output of the clock. In this way, a miniature all-optical atomic clock is realized. Details of the operation of the clock and application of the architecture to other atomic systems, such as a ytterbium ion, will be described.

9616-21, Session 6

Radiation studies on silicon photonic ring resonators

Sharon M. Weiss, Shweta Bhandaru, Shuren Hu, Daniel M. Fleetwood, Vanderbilt Univ. (United States)

Silicon ring resonators are considered to be among the most important building blocks for emerging optical interconnect technology, and are expected to complement, or in some cases replace, microelectronics components. In this work, we evaluate the performance of silicon ring resonators exposed to 10-keV x-ray and 662-keV gamma radiation. Unpassivated rings having no native oxide exhibit a distinct, dose-dependent response, which can lead to a more than 10 dB change in transmission for an x-ray or gamma ray total ionizing dose near 145 krad(SiO2). Silicon ring resonators that have been passivated with native oxide or a polymer coating exhibit no dose-dependent response, but are sensitive to ambient temperature fluctuations. The role of surface passivation in the radiation sensitivity of silicon ring resonators will be discussed in detail. It is believed that surface oxidation is accelerated in the presence of high energy radiation but, at room temperature conditions, the surface oxidation is limited to a terminal native oxide. With appropriate temperature compensation considerations, passivated silicon photonic ring resonators are likely to perform reliably in harsh radiation environments.

9616-22, Session 6

Compact, highly sensitive optical gyros and sensors with fast-light *(Invited Paper)*

Caleb A. Christensen, Anton Zavriyev, Malcolm Cummings, A. Craig Beal, Mark Lucas, Michael J. Lagasse, MagiQ Technologies, Inc. (United States)

Fast-light phenomena can enhance the sensitivity of an optical gyroscope of a given size by several orders of magnitude, and could be applied to other optical sensors as well. MagiQ Technologies has been developing a compact fiber-based fast light Inertial Measurement Unit (IMU) using Stimulated Brillouin Scattering in optical fibers with commercially mature technologies. We will report on our findings, including repeatable fast-light effects in the lab, numerical analysis of noise and stability given realistic optical specs, and methods for optimizing efficiency, size, and reliability with current technologies. The technology could benefit inertial navigation units, gyrocompasses, and stabilization techniques, and could allow high grade IMUs in spacecraft, unmanned aerial vehicles or sensors, where the current size and weight of precision gyros are prohibitive. By using photonic integrated circuits and telecom-grade components along with specialty fibers, we also believe that our design is appropriate for mass production without further advances in the state of the art.

9616-23, Session 7

Polymer light harvesting composites for optoelectronic applications *(Invited Paper)*

Sam-Shajing Sun, Dan Wang, Norfolk State Univ. (United States)

Polymer based optoelectronic composites and thin film devices exhibit great potential in space applications due to their lightweight, flexible shape, high photon absorption coefficients, and robust radiation tolerance in space environment. Polymer/dye composites appear promising for optoelectronics applications due to potential enhancements in both light harvesting and charge separation. In this study, the optoelectronic properties of a series of molecular dyes paired with a conjugated polymer P3HT were investigated. Specifically, the solution PL quenching coefficients (Ksv) of dye/polymer follows a descending order from dyes of Hemin, Protoporphyrin, to TCPP. In optoelectronic devices made of the P3HT/dye/PCBM composites, the short circuit current densities Jsc as well as the overall power

conversion efficiencies (PCE) also follow a descending order from Hemin, Protoporphyrin, to TCPP, despite Hemin exhibits the intermediate polymer/dye LUMO offset and lowest absorption coefficient as compared to the other two dyes, i.e., the cell optoelectronic efficiency did not follow the LUMO offsets which are key electron transfer driving forces. This study reveals that too large LUMO offset or electron transfer driving force may result in smaller PL quenching and optoelectronic conversion efficiency, this could be another experimental evidence for the Marcus electron transfer model, particularly for the Marcus 'inverted region'. It appears an optimum electron transfer driving force or strong PL quenching appears more critical than absorption coefficient for optoelectronic conversion devices.

9616-24, Session 7

MEMS based solutions for an integrated and miniaturized multi-spectrum energy harvesting and conservation system *(Invited Paper)*

Heath A. Berry, Eric G. Borquist, Mitchell Belser, Radiance Technologies, Inc. (United States); Sandra Zivanovic, Leland Weiss, Louisiana Tech Univ. (United States)

As the mission of NASA shifts and expands, so too does the need for reliable, energy harvesting technology. Moving further out into the realms of space requires efficient use of the energy present in this unique, and more often than not, harsh environment. This paper describes the development of a unique system consisting of three unique energy harvesting technologies which utilize multiple MEMS and materials development based approaches which are being integrated together using a system-in-package approach. By developing multiple scavenging approaches, NASA will be able to harvest energy from multiple waste energy sources, namely environmental vibrations, thermal energy, and solar flux.

For this system, solar harvesting is accomplished through the use of an amorphous silicon thin-film solar cell with a special metal-dielectric composite electrode (MDCE) that enhances photovoltaic action through excitation of surface plasmons. Additionally, a MEMS-based heat exchanger has been developed for use in conjunction with TEGs as heat sinks for thermal capture. These micro-channel heat exchangers have advantages with respect to transport phenomena, size, and manufacturing. The MHE is one part of the thermal scavenging device. A thermal energy storage system has been fabricated to store excess thermal energy. This energy can be used after the thermal source is removed from the process. Finally, a MEMS based vibration capture element has also been developed for vibration rich environments. All three of these energy capture technologies are being integrated together for a flexible platform which can facilitate the remote collection and transmission of pertinent environmental and mission data.

9616-25, Session 8

Towards ultra-lightweight photonics using atomically thin semiconductors

Vinod M. Menon, The City College of New York (United States)

In this talk I will present an overview of nanophotonic technologies that can be realized using atomically thin two-dimensional semiconductors. Specific applications areas such as light emitters, detectors and ultrafast modulators will be discussed. The different types of two-dimensional materials and their advantages in the different application areas will also be highlighted.

9616-26, Session 8

Radiation damage effects in a CMOS TDI image sensor

Joseph E. Rushton, Konstantin D. Stefanov, Andrew D. Holland, The Open Univ. (United Kingdom)

Time Delay and Integration (TDI) is used to increase the signal to noise ratio in image sensors when imaging fast moving objects. One important TDI application is in Earth observation from space. In order to operate in the space radiation environment, the effect that radiation damage has on the performance of the image sensors must be understood.

This work looks at prototype TDI sensor pixel designs, produced by e2v technologies. The sensor is a CCD-like charge transfer device, allowing in-pixel charge summation, produced on a CMOS process. The use of a CMOS process allows potential advantages such as lower power consumption, smaller pixels, higher line rate and extra on-chip functionality which can simplify system design. CMOS also allows a dedicated output amplifier per column allowing fewer charge transfers and helping to facilitate higher line rates than CCDs.

In this work the effect on the pixels of radiation damage from high energy protons, at doses relevant to a low Earth orbit mission, is presented. This includes the resulting changes in Charge Transfer Efficiency (CTE) and dark signal.

9616-27, Session 9

Microscopic model for studying radiation degradation of electron transport and photodetection devices *(Invited Paper)*

Danhong Huang, Air Force Research Lab. (United States); Fei Gao, Univ. of Michigan (United States); David A. Cardimona, Christian P. Morath, Vicent M. Cowan, Air Force Research Lab. (United States)

A microscopic-level model is proposed for exploring degraded performance in electron transport and photodetection devices, based on pre-calculated results as initial conditions for meso-scale approaches, including ultra-fast displacement cascade, intermediate defect stabilization and cluster formation, and slow defect reaction and migration. The steady-state spatial distribution of point defects in a mesoscopic-scale layered system will be studied by taking into account the planar dislocation loops and spherical neutral voids as well. The electronic structure of point defects will also be computed by employing density-functional theory for both energy levels within energy gap and their localized wave functions. These theoretical efforts are expected to be crucial in fully understanding the physical mechanism for identifying defect species, performance degradations, and the development of mitigation strategies. Additionally, verification of the current model by device characterization is discussed.

9616-28, Session 9

Atomistic- and meso-scale simulations of radiation effects in photodetection devices *(Invited Paper)*

Fei Gao, Efrain Hernandez-Rivera, Univ. of Michigan (United States); Danhong Huang, Air Force Research Lab. (United States)

Atomistic- and meso-scale models are developed to study behavior of defect evolution in compound semiconductors, which gives rise to performance degradation of electron photo-response. Large-scale molecular dynamics (MD) simulations are used to investigate defect generation, clustering and distribution, as well as their mobilities and stabilities in compound semiconductors. A kinetic Monte Carlo method is employed to follow the evolution of clusters and their interaction with microstructures at time scale much longer than possible with MD simulation. Based on these simulations, defect/property relationships, the effects of defects on transport processes and the aggregation of defects to form complex nanostructures are expect to be established. We also describe how the fundamental mechanisms and knowledge gained from atomic- and meso-scale simulations can be used to inform rate-diffusion theory or cluster

dynamics in the form of initial conditions. This enables us to determine the steady-state distribution of point defects in a mesoscopic layered-structured system, thus allowing the development of a multi-timescale theory to study radiation degradation in electronic and optoelectronic devices.

9616-29, Session 9

Surface conduction in InAs and GaSb

Daniel E. Sidor, Gregory R. Savich, Gary W. Wicks, Univ. of Rochester (United States)

III-V semiconductor materials belonging to the 6.1 Å family (InAs, GaSb, AlSb, and their alloys and superlattices) are increasingly used to produce high performance MWIR and LWIR photodetectors. Barrier architecture detectors fabricated from these materials exhibit competitively low dark current densities compared to state-of-the-art pn-based structures. Appropriately placed unipolar barriers within these structures serve to block dark currents arising from growth- and/or processing-related defects. They are also effective at blocking dark currents arising from radiation-induced defects, such as those occurring in space-bound systems.

A challenge inherent to working with these materials is their conducting surfaces: InAs possesses an n-type surface, and GaSb possesses a p-type surface. Care must therefore be taken to avoid fabricating structures in which surface conduction pathways unintentionally shunt bulk conduction. The detrimental effects of conducting surfaces become more significant as device size is reduced, making this a particularly important consideration for applications where detector package size and weight are constrained.

This work presents a fundamental investigation of the surface conduction pathways occurring in devices fabricated from InAs and GaSb. The component of current due to surface conduction is extracted from current-voltage measurements by its dependence on device size and temperature. InAs is found to have a temperature-independent surface conductivity greater than 10^-7 reciprocal ohm-square. The surface conductivity of GaSb is an order of magnitude smaller than that of InAs at room temperature, and when cooled it decreases with a thermal activation energy of approximately 90 meV, which is equal to the known separation between the valence band and surface Fermi level. The temperature dependences of the surface conductivities of the two materials indicate that the surface of InAs is degenerate and the surface of GaSb is non-degenerate.

Extensions of these findings to 6.1 Å alloys and superlattices will be discussed.

9616-30, Session 9

Radiation effects on Yb:YLF crystals used in cryogenic optical refrigerators

Kyle W. Martin, Applied Technology Associates (United States); Tom Fraser, John E. Hubbs, Vicent M. Cowan, Air Force Research Lab. (United States); Seth D. Melgaard, Mansoor Sheik-Bahae, The Univ. of New Mexico (United States)

Optical cooling of solids is a promising and innovative method to provide cryogenic cooling to infrared sensors. Currently insulator crystals, specifically ytterbium-doped yttrium- lithium-fluoride (Yb:YLF), have shown the most promise for cooling to low temperatures. This method has demonstrated cooling below the National Institute of Standards and Technology (NIST) cryogenic temperature definition of less than 123 K. Optical refrigeration utilizes a phenomenon called anti-Stokes fluorescence to generate cooling power. Incident laser light is absorbed by the cooling crystal and photons are spontaneously emitted at a higher, and thus more energetic, frequency. The difference in frequency is proportional to the cooling power of the crystal. Anti-Stokes cooling is highly dependent on doping percentages and YLF crystal purity and structure. Space based infrared sensors and their coolers live in a harsh radiation environment. To ensure that radiative effects on cooling crystal background absorption and resonant absorption parameters is minimal we subjected two samples to a total ionizing dose of 100 Krad and 1 Mrad, and compared cooling crystal efficiency parameters before and after dosing.

9616-31, Session 9

Potential of CdSiP2 for enabling mid-infrared laser sources

F. Kenneth Hopkins, Air Force Research Lab. (United States); Peter G. Schunemann, Kevin T. Zawilski, BAE Systems (United States); Nancy C. Giles, Air Force Institute of Technology (United States); Larry E. Halliburton, West Virginia Univ. (United States)

Laser sources operating near a wavelength of four microns are important for a broad range of space and airborne applications. Efficient solid-state laser sources, demonstrating the highest power, are based upon nonlinear optical (NLO) conversion using the NLO crystal ZnGeP2. However, a related NLO crystal, CdSiP2, is now under investigation by several groups around the world due to its potential to out-perform ZnGeP2. The crystal's characteristics as well as efforts to understand the crystal's defects that presently limit NLO performance will be discussed.

9616-32, Session 9

Deflection of uncooperative targets using laser ablation

Nicolas Thiry, Massimiliano Vasile, Univ. of Strathclyde (United Kingdom)

Owing to their ability to move a target in space without requiring propellant, laser-based deflection methods have gained attention among the research community in the recent years. With laser ablation, the vaporized material is used to push the target itself allowing for a significant reduction in the mass requirement for a space mission. Specifically, this paper addresses two important issues which are thought to limit seriously the potential efficiency of a laser-deflection method: the impact of the tumbling motion of the target as well as the impact of the finite thickness of the material ablated in the case of a space debris. In this paper, we developed a steady-state analytical model based on energetic considerations in order to predict the efficiency range theoretically allowed by a laser deflection system in absence of the two aforementioned issues. A numerical model was then implemented to solve the transient heat equation in presence of vaporization and melting and account for the tumbling rate of the target. This model was also translated to the case where the target is a space debris by considering material properties of an aluminium T6061 alloy and adapting at every time-step the size of the computational domain along with the recession speed of the interface in order to account for the finite thickness of the debris component. The comparison between the numerical results and the analytical predictions allow us to draw interesting conclusions regarding the momentum coupling achievable by a given laser deflection system both for asteroids and space debris in function of the flux, the rotation rate of the target and its material properties.

9617-4, Session PWed

Development of an extreme adaptive optics testbench using a self-referenced Mach-Zehnder wavefront sensor

Christian Delacroix, Magali Loupias, Maud P. Langlois, Michel Tallon, Éric M. Thiébaut, Ctr. de Recherche Astrophysique de Lyon (France)

Extreme adaptive optics (XAO) has severe difficulties meeting the high speed (>1kHz), accuracy and photon efficiency requirements. An innovative high order adaptive optics system using a self-referenced Mach-Zehnder wavefront sensor allows counteracting these limitations. This sensor estimates the wavefront phase by measuring intensity differences between two outputs, with a lambda/4 path length difference, but is limited by its dynamic range. During the past few years, such an XAO system has been studied by our team in the framework of 8-meter class telescopes. In this work, we report on our latest results with the XAO testbed recently installed in our lab, and dedicated to high contrast imaging with 30m-class telescopes (such as the E-ELT or the TMT). A woofer-tweeter architecture is used in order to deliver the required high Strehl ratio (>95%). It consists of a 12x12 deformable mirror and a 512x512 spatial light modulator, characterized using both mono- and polychromatic light. We present our latest simulation and laboratory demonstration results, including components characterization, close loop performance, and sensitivity to calibration errors. This work is carried out in synergy with the validation of fast iterative wavefront reconstruction algorithms, and the optimal treatment of phase ambiguities in order to mitigate the dynamical range limitation of such a wavefront sensor.

9617-16, Session PWed

Single wave-front sensor control deformable mirrors: theory and experiment

Ye Hongwei, Shen Feng, Zhou Rui, Institute of Optics and Electronics (China)

Adaptive optics (AO) systems are used in image systems to compensate the phase disturbance caused mainly by atmospheric turbulence. The compensation performance of AO system largely depends on the fitting capability of the deformable mirror (DM). In the same work condition, large correction stroke and high spatial performance are demanded simultaneously. This demand is difficulty to satisfy with single DM. It's perfectly feasible by disassemble the control voltage of the ideal compensation wave-front to control many deformable mirrors work together. There are some papers analyzing the compensation effect using many deformable mirrors. Such as the scheme using double deformable mirrors to avoid the instability of thermal blooming phase correction was studied in Ref. The double deformable mirrors adaptive optics system which corrects the turbulence and the scintillation was discussed in Ref. In this paper, we will deduce a kind of decoupling algorithms. By disassemble the control voltage of the compensation wave-front to make double or many deformable mirrors work together. Low spatial frequency deformable mirror (LFDM) compensate the low order wave-front aberration using the Zernike decomposition the actuators control voltages of high spatial frequency deformable mirror(HFDM). High spatial frequency deformable mirror (HFDM) compensate all the residual aberration using the direct-gradient algorithm. the dynamic models of Zernike modal compensation for the direct-gradient algorithm were established in this paper. By using the theoretic model, A single wave-front sensor Control double deformable mirrors were tested on a adaptive optical system including 45-element deformable mirror and 199-element deformable mirror in channel turbulence. The experiment data proved that the single wave-front sensor control double mirrors adaptive optical system could improve ability of large wave-front compensation.

Direct detection of phase coded signal for ranging in synthetic aperture LADAR

Guangyu Cai, Jianfeng Sun, Yu Zhou, Xiaoping Ma, Peipei Hou, FuChuan Liu, Liren Liu, Shanghai Institute of Optics and Fine Mechanics (China)

Ranging ability has always been the fundamental function of Ladar, which has also integrated the detection of other information including Doppler frequency shift in ranging Doppler ladar, imaging in synthetic aperture ladar and three-dimensional imaging ladar etc.. Traditional mechanisms using phase coded optical waveforms for ranging compression in coherent ladar generally adopted local oscillator for heterodyne detection to demodulate the delayed modulation signal, which requires complex receiving structure as well as the master and local oscillators' high frequency stability.

A new detection structure similar to the direct-detection of DPSK signals was proposed in which two orthogonal polarized beams were split with one-bit delay mutually before interference and entering a balanced heterodyne receiver. The one bit difference form of the compressible codes were loaded on the phase modulator in order to demodulate the correct waveform. Various compressible sequences were verified and high precision ranging results were achieved. A relatively higher detection sensitivity was accomplished compared to the intensity modulated direct detection(IM-DD) sequence coding method which was also conducted in the experiment. In addition to the rich waveform diversity which could be tailored to various detecting applications and the high repetition frequency common to the phase coded ranging methods, there are unique advantages of this receiving structure such as the cancellation of the phase errors and frequency shift introduced in the propagation process by the two interfered receiving arms. Moreover, the polarization based detection structure also provided compatibility to the down-looking synthetic aperture ladar with its ranging capability.

9617-18, Session PWed

Imaging signal-to-noise ratio of synthetic aperture LADAR

Liren Liu, Shanghai Institute of Optics and Fine Mechanics (China)

In a synthetic aperture ladar (SAL) the detected optoelectronic signal is temporal, but the output is a 2D image in the time-frequency and distance domain due to the focusing algorithm for imaging. Thus the resulted SNR in an image is different from the SNR in the reception which was well estimated before. So it is interesting to find the 2D SNR in the image space.

In this paper in terms of the photocurrent statistics the noise power spectrum of photocurrent as well as the other sources is first established, and then the relation of the image in power to the noise power background in the orthogonal direction of travel is mathematically figured out, which are connected with the transfer function of detector circuit, the integration time for focusing and the image width in this direction. The SNR is further accumulated along the travel direction. The 2D imaging SNR is derived for the down-looking SAL and side-looking SAL using the p-i-p photodiode or the avalanche photodiode. It is therefore seen that the imaging SNR is inherently enhanced in comparison with the SNR in the reception, the transfer function bandwith should be large enough to stabilize the image intensities and the increase of the integration time will increase both the image intensity and SNR.

On this base, we can correctly design a SAL system with the suitable

parameters such as the received optical power of signal, the dark-current noise, the transfer function of detector circuit, the integration time for focusing and the 2D image width.

9617-19, Session PWed

Improvement of the signal-to-noise ratio in static-mode down-looking synthetic aperture imaging LADAR

Zhiyong Lu, Jianfeng Sun, Ning Zhang, Yu Zhou, Guangyu Cai, Liren Liu, Shanghai Institute of Optics and Fine Mechanics (China)

This paper presents a static mode synthetic aperture imaging ladar. The static mode synthetic aperture imaging ladar in which the target and carrying-platform were kept still during the collection process was proposed and demonstrated. The return signal energy can be collected with more time due to the target is irradiated continuously. The signal-to-noise ratio can be enhanced in this mode synthetic aperture imaging ladar. Compare to the traditional side-looking and trip-mode down-looking synthetic aperture imaging ladar, which can't keep the beam locating on the same target all the time, the static mode synthetic aperture imaging ladar has an advantage to the system sensitivity. We could obtain the remote target image at very low return levels. In the experiment, the target is 10m distance from the transmitting telescope, and power of the laser is about 3mW. The target image is rebuilt in different collected time. As the increasing of the illumination time, the clearer image is reconstructed. This technique has a great potential for applications in extensive synthetic aperture imaging ladar fields.

9617-21, Session PWed

Measurement of polarization parameters of the targets in synthetic aperture imaging LADAR

Qian Xu, Jianfeng Sun, Wei Lu, Peipei Hou, Zhiwei Sun, Zhiyong Lu, Xiaoping Ma, Liren Liu, Shanghai Institute of Optics and Fine Mechanics (China)

Synthetic aperture imaging ladar (SAIL) is the most possible optical method to provide centimeter-class resolution with a real aperture size of a few meters in thousand kilometers. Recently the techniques of SAIL have been found more attention and increasing applications in the field of remote sensing. In the SAIL, the polarization state change of the backscattered light will affect the image quality. Polarization state of the reflected field is always determined by the interaction of the light and the materials on the target plane, which related to the permittivity, roughness, even the surface structure of the material. The Stokes parameters can provide the information both on light intensity and on polarization state, thus can be recognized as the ideal quantities for characterizing the above features. In this paper, a measurement system of the polarization characteristic for the SAIL target materials is designed, which uses a laser operating at the wavelength of 1030nm. The results are expected to be useful in target identification and recognition.

A balanced APD photodetection technology for large field of view coherent receiver

Guo Zhang, Zhou Yu, Jianfeng Sun, Baoliang Li, Liren Liu, Guang-Yu Cai, Shanghai Institute of Optics and Fine Mechanics (China)

In the Siegman antenna theory, the effective aperture integrated over all possible arrival directions (all solid angle) is essentially the signal wavelength squared. Improving only the solid angular field of view or the effective aperture does not improve the final SNR, so increasing the field of view and the effective receiving aperture while ensuring a higher signal to noise ratio of the received signal has become a key limitation of coherent receiver in large field of view and high sensitivity photodetection application.

Currently, the near-infrared single photon detection system has high sensitivity. It can detect weak near-infrared optical signal, but the near-infrared single photon detection system needs avalanche photodiode(APD) operating in Geiger mode, however, the coherent receiver requires APD to operate in linear mode, so designing a system for coherent receiver to increase the photodetection field of view and sensitivity is very important.

In this paper a kind of balanced APD photodetection system which uses APD operating in the linear mode as a photoelectric conversion unit to improve the photodetection sensitivity and balanced photodetection technology to improve the signal to noise ratio for coherent receiver system is designed. Theoretical analysis of the key specifications of the balanced APD photodetection system including stability, noise equivalent power, gain, bandwidth, etc. is given. Corresponding optical detection experiments are conducted on the designed balanced APD photodetection system to verify its advantages of greatly improving the field of view and sensitivity, which satisfy the coherent receiver's requirements.

Resampling technique in the orthogonal direction for down-looking SAIL

Guangyuan Li, Jianfeng Sun, Zhiyong Lu, Ning Zhang, Guang-Yu Cai, Zhiwei Sun, Liren Liu, Shanghai Institute of Optics and Fine Mechanics (China)

The down-looking synthetic aperture imaging ladar(SAIL) with a transmitter of two coaxial and scanned polarization-orthogonal beams of spatial spherical and parabolic phase difference and a receiver of self-heterodyne detection in laboratory and outdoor has been constructed and demonstrated. The implementation of synthetic aperture imaging uses quadratic phase history reconstruction in the travel direction and linear phase modulation reconstruction in the orthogonal direction through Fourier transform.

The linear phase modulation in the orthogonal direction of travel is generated by the shift of two cylindrical lens in the two polarization-orthogonal beams. Therefore, the fast-moving of two cylindrical lens is necessary for airborne down-looking SAIL to match the aircraft flight speed and to realize the compression of the orthogonal direction, but the quick stop and the quick start of the cylindrical lens must greatly damage the motor. To reduce the damage, we make the motor move like a sinusoidal curve to make it more realistic movement, and propose a resampling interpolation imaging algorithm, through which we can transform the nonlinear phase to linear phase.

Three different resampling interpolation methods are analyzed, and we get good reconstruction results of point target and area target in laboratory compared with the results under linear phase modulation. The influences on imaging quality in different sampling positions when the motor make a sinusoidal motion are analysed. At last, we performe a comparison of the results of the two cases in resolution.

9617-24, Session PWed

A demonstrator of all-optronic multifunctional down-looking synthetic aperture LADAR

Wei Lu, Zhiyong Lu, Zhiwei Sun, Ning Zhang, Jianfeng Sun, Lijuan Wang, Liren Liu, Shanghai Institute of Optics and Fine Mechanics (China)

A synthetic aperture ladar can provide two-dimensional active imaging of centimeter-class resolution at a long range. Recently an idea of down-looking synthetic aperture ladar (DL SAL) was developed, which represents a completely new structure of SAL and has the important features such as a big coverage with an enhanced receiving aperture and little influence from atmospheric turbulence and other factors. However a DL SAL has much bigger coverage area than a side-looking SAL, a flow of high-resolution images will produce a large amount of data. It is thus predicted that the further improvement to enhance the processing speed from data acquisition to image reconstruction by using an all optical sensing-to-processing chain is useful.

In this paper, the design and laboratory experiment of a demonstrator of all-optronic DL SAL is presented. The demonstrator consists of a DL SAL unit with an optical scanner for transmitting and receiving beams and an optical processor. The designed DL SAL unit is able to function in one of the strip-map mode, spotlight mode or static mode. The optical processor is simple in construction and reconstructs the image in real time and in parallel. From the experiments the ultra-fast processing capability from image acquisition to real-time reconstruction is shown, the all-optical design would provide a compact, lightweight and on-board DL SAL system.

The DL SAL unit uses two coaxial orthogonally polarized beams in transmitter and polarization interference based self-heterodyning detection in receiver. And the linear phase modulation necessary to obtain the target range information in the orthogonal direction of travel is generated by the projection of two cylindrical lenses with a mutual shifting and the quadratic phase modulation necessary to achieve the target phase history in the travel direction is produced by the projection of other two cylindrical lenses, movable if needed. By managing the mutual movement of the SAL and target, the scanner and the cylindrical lenses, therefore, different working modes can be realized. In principle the acquired 2D data is processed to reconstruct the 2D image of target in terms of a focusing algorithm with the Fourier transform in the crossed direction and the matched filtering with a conjugate quadric phase of phase history in the travel direction. Accordingly, the optical processor is designed as an astigmatic optical system, which reduces to a 4-f Fourier transform system in the plane containing the orthogonal direction of travel and functions the free-space propagation with the Fresnel diffraction in the plane containing the travel direction thus to yield the matched filtering with a quadric phase. A spatial light modulator is used as the input interface of the processor, on which the 2D data output from the DL SAL unit are displayed, so that the focused 2D image of the target is visually observed on the processor output plane. A SAL works inherently on the propagation condition of far-field. The experimental verification and test of the all-optronic DL SAL demonstrator in the laboratory space is carried out in a simulated far-field condition by using an optical collimator with a lens of long focal length. Various experimental results are resulted.

Dual-mode photosensitive arrays based on integration of liquid crystal microlenses and CMOS sensors for obtaining intensity images and wavefronts

Qing Tong, Yu Lei, Huazhong Univ. of Science and Technology (China)

As we all know, because the index of refraction of the conventional microlens array (MLA) is not variable, the wavefront sensor based on the conventional MLA can only obtain the intensity image with low-resolution when it is used to test the wavefront information simultaneously. So we use the dual-mode photosensitive arrays based on the liquid crystal (LC) MLA and CMOS sensors to obtain both intensity images with high-resolution and wavefronts. The LC MLA is adjoining to the CMOS sensors. When the voltage is applied the LC MLA forms an array of spots on the focal plane, and the LC MLA without voltage looks like a piece of glass. Therefore the dual-mode photosensitive arrays can work between an imaging mode and a wavefront mode by switching the voltage off and on. Moreover we can test the wavefronts in a certain area with a certain resolution and the wavefronts or images in other areas with other resolutions at the same time by using the LC MLA with multi-layered and divisional top patterned electrodes. The field of the view of the LC MLA is also variable by changing the voltage in theory. Now we are doing the experiments to compare the composite wavefronts of the object exposured in a white light source (ARC LAMP SRC F/1 COLL COND, Newport Corporation) with the wavefronts of the same object in tricolor laser sources (Red: 671nm; Green: 532nm; Blue: 473nm, Changchun New Industries Optoelectronics Tech. Co., Ltd (CNI)), to prove that the composite wavefronts of the white light can be used to test the wavefront information. And we will do the researches mentioned before in the next work. Because of the absorption of the indium tin oxide (ITO) to the infrared (IR) light is very strong, the LC MLA with ITO electrode can only be used in the visible spectrum now, however we are finding other material to replace the ITO, so that the LC MLA can be used in the IR.

Some characteristics of the E-ELT's "sodium LGSs"

Nourredine N. Moussaoui, Univ. des Sciences et de la Technologie Houari Boumediene (Algeria)

The characteristics of the sodium Laser Guide Stars "LGSs" could be severely affected by the action of several parameters. We propose in this paper to estimate the effect of some parameters on the "sodium LGSs" of the European-Extremely Large Telescope "E-ELT". The laser guide star photon return flux and consequently the laser power requirement are driven by the spot elongation. It is essential to know the evolution of this parameter, in order to optimize the characteristics of the sodium laser guide star. The angular spot elongation as observed on the ground is evaluated taking into account the temporal evolution of the mesospheric sodium layer. The sodium layer thickness and its centroid height impact strongly the LGSs spot size.

The magnitude of these guide stars could be severely affected by the earth's magnetic field. Even the intensity of this field is not very strong; it can cause a transfer of the atomic population from one sublevel to another one. This is called a redistribution of the atomic population between the magnetic sublevels. So, we have to take into account this effect in the determination of the "sodium LGSs" characteristics. In this paper, we present an analytical approach to calculate the occupation probabilities of the sodium magnetic sublevels in presence of a magnetic field. We focus on the magnetic sublevels of the sodium D2a transitions. This work aims to estimate the effect of the geomagnetic field on the characteristics of the "sodium LGSs" produced by circularly polarized laser beam.

Multi-conjugate adaptive optics (MCAO): analysis and assessment

Katharine J. Jones, WBAO Consultant Group (United States)

Multi-conjgate Adaptive Optics (MCAO) is an essential approach to wavefront sensing and control. The concept of MCAO corrects each "layer" of the atmosphere independently. Correction devices (deformable mirrors) are placed in "series" and assigned one layer of atmosphere to correct the isoplanatic patch. MACAO can be approached two ways: with multi-guide stars or multi;ayer correction. The objective of this paper is to analyze both approaches and assess their effectiveness to achieve their goals. Wavefront correction is being carried out in the Large Binocular Telescope (LBT) by means of multiple Laser Guide Stars. Multi-llayer correction is being achieved by the Solar telescope GREGOR. The Large Binocular Telescope achieves MCAO by using two different Laser Guide Stars. Il uses four Rayleigh beacons at 532 nm for each of two 8.4 m component telescopes. Six Rayleigh guide stars are oriented as equilateral triangles. Sodium LGS AO correction will be added to the LBT at a later stage at 589 nm. The Solar telescope GREGOR achieves MCAO by employing three deformable mirrors at different levels above the ground in series.This paper will analyzed both multi-wavelength and multi-level MCAO for effectiveness in compensating turbulence for distortion correction.

9617-2, Session 1

Wavefront-sensor tomography for measuring spatial coherence

Bohumil Stoklasa, Libor Motka, Jaroslav Rehacek, Zdenek Hradil, Palacky Univ. Olomouc (Czech Republic); Luis Lorenzo Sánchez-Soto, Univ. Complutense de Madrid (Spain)

The operation of wavefront sensors is most often understood in an oversimplified geometrical-optics framework, which is much the same as assuming full coherence of the detected signal. However, this is not a complete picture: even in the simplest instance of beam propagation, the knowledge of the coherence features turns out to be essential. We confine ourselves to the example of the Shack-Hartmann (SH) sensor. An incoming light field is dividend into a number of sub-apertures by a microlens array that creates focal spots, registered in a CCD camera. The deviation of the spot pattern from a reference measurement allows the local direction angles to be derived, which in turn enables the reconstruction of the wavefront. Unfortunately, this geometric picture breaks down when the signal is partially coherent, because the very notion of a single wavefront becomes somewhat ambiguous: the signal has to be conceived as a statistical mixture of many wavefronts. To circumvent this difficulty, we observe that these sensors provide a simultaneous detection of position and angular spectrum (i.e., directions) of the incident radiation, which is determined by the position of the detected signal on the CCD. In other words, SH measurements are pertinent examples of simultaneous unsharp position and momentum measurements, a question of fundamental importance in quantum theory. In this contribution we will point out that common wavefront sensors can be utilized for measuring mutual coherence and hence 3D imaging of partially coherent fields provided quantum state reconstruction techniques are adopted for data processing.

9617-5, Session 1

Digital holography wave-front sensing in the presence of strong atmospheric turbulence and thermal blooming

Mark F. Spencer, Air Force Research Lab. (United States); Michael J. Steinbock, Air Force Institute of Technology (United States)

Digital holography wave-front sensing shows distinct potential for directed-energy and remote-sensing applications. For instance, digital holographic detection provides access to the amplitude and wrapped phase associated with an optical field. From the wrapped phase, one can estimate the atmospheric aberrations present and perform adaptive-optics compensation and high-resolution imaging. This paper develops wave-optics simulations which explore the estimation accuracy of digital holography wave-front sensing in the presence of strong atmospheric turbulence and thermal blooming. Specifically, this paper models plane-wave propagation through varying atmospheric conditions along a horizontal propagation path and formulates the field-estimated Strehl as a function of the log-amplitude variance, the distortion number, and the ratio of the detector plane pixel size to the coherence diameter. Such results will allow one to assess the number of pixels needed in a detector array when using digital holography detection in the presence of strong atmospheric turbulence and thermal blooming.

Three-dimensional polarimetric imaging in a snapshot

Sudhakar Prasad, Z. Yu, The Univ. of New Mexico (United States)

A recent proposal [1] based on encoding the axial depth of a narrow-band point source in the angle of rotation of its off-axis image has greatly enhanced the prospects of full three-dimensional (3D) localization of point sources over a large 3D field with high transverse and axial resolution. This new approach has added to the host of other rotating point spread functions (PSFs), including the double-helix [2,3] and corkscrew PSFs [4], already available for 3D localization, particularly for application to single-molecule biological microscopy. Combining information about the 3D location and polarization state of the source is of vital interest in this application, in which the polarimetric information may uniquely reveal the nature of the local biological environment of the source dipole [5]. In other applications, such as remote sensing, such combined information may localize with high contrast specularly reflecting objects against a diffusely scattering background [6]. In the present work, we carefully treat the non-paraxial nature of light propagation over a large imaging aperture in high numerical-aperture (NA) microscopy using the rotating PSF of Ref. [1]. Such propagation is attended by nontrivial vector dependences of the radiation fields, which can encode information about the full 3D dipolar state of the emitter in the spatial brightness distribution, or its image, acquired by the microscope sensor. By placing a phase mask with a zoned spiral phase structure in a conjugate plane of the imaging aperture [1], one can create a coherent superposition of approximate Bessel beams of varying orbital angular momentum (OAM) quantum numbers and thus also acquire information about the 3D spatial location of the emitter via the center and angle of rotation of the PSF that results from the focusing of such a superposition. We describe the results of our theoretical work and simulations based on this theory for acquisition and recovery of joint 3D polarimetric information of point dipole emitters in a large 3D field in the snapshot mode, which offers the promise of rapid, perhaps video-rate, polarimetric 3D localization microscopy. The use of a q-plate [7], which is a fixed-wave phase plate but with a local axis of birefringence that rotates with the azimuthal angle coordinate of the position on the plate, allows conversion of the spin angular momentum (SAM) of the imaging beam, which is directly controlled by the state of polarization of the dipole emitter, into a corresponding OAM state. Combining a q-plate with the spiral phase mask of the type proposed in Ref. 1 then permits the acquisition of 3D polarimetric information without the need for high-NA microscopy, and opens the way for its use in typically ultralow-NA telescopic imaging as well. We shall also briefly discuss a theoretical analysis of this model and computer simulations exploiting it for joint 3D polarimetric-localization imaging in a snapshot.

9617-7, Session 2

Geometric superresolution by scanning two rect masks - with relative path difference

Ihtsham U. Haq, National Physical and Standard Lab.

(Pakistan) and Pakistan Institute of Engineering and Applied Sciences (Pakistan) and Pakistan Council of Scientific and Industrial Research (Pakistan); Asloob A. Mudassar, Pakistan Institute of Engineering and Applied Sciences (Pakistan); Ihtram U. Haq, Univ. of Karachi (Pakistan)

Today, in everyday imaging in science and research, a digital imager – despite of its lower resolution than conventional film camera, is the first choice due to its obvious advantages. Assuming the imaging system to be diffraction limited, this low resolution is due to two geometrical characteristics of the detector array (CCD/CMOS) used in it at image plane. These two characteristics are pitch and non-zero pixel size – which do sampling and averaging of optical information over pixel spatial area respectively and dictates geometric resolution limit of digital imager.

In this paper, we are proposing a geometric superresolution technique based on scanning of composite rect masks (CRM) over CCD. The two different composite masks are realized from two component Rect masks by introducing zero and single subpixel path difference between them. The CRM are scanned over CCD by half pixel in subpixel steps. The CRM optically codes the image over CCD– which is then decoded computationally from recorded coded digital images to get a super-resolved image – which is spatially enhanced in resolution by subpixel factor. This virtually replaces each CCD pixel by a matrix of subpixels. The decoding process is executed in just one mathematical step. The widths of the component Rect masks are set to achieve maximum SNR – keeping the system deterministic under relative scanning of these masks over CCD.

The 2D simulation results are presented – showing an improvement in resolution by given super-resolution factor - in both x and y directions. Increasing the super-resolution factor more makes the result more close to original. The given superresolution technique can be applied to microscopy, medical imaging, machine vision, industrial inspection, metrology (dimensional metrology, optical metrology), defense, satellite imaging and astronomy.

9617-8, Session 2

Laboratory validation of a sparse aperture image quality model

Philip S. Salvaggio, Rochester Institute of Technology (United States)

The majority of image quality studies in the field of remote sensing have been performed on systems with conventional aperture functions. These systems have well-understood image quality tradeoffs, characterized by the General Image Quality Equation (GIQE). However, in order to continue pushing the boundaries of imaging, more control over the system's point-spread function is needed. Examples include sparse apertures, synthetic apertures, coded apertures and phase elements. As a result of the non-conventional point spread functions of these systems, post-processing becomes a critical step in the imaging process and artifacts arise that are more complicated than simple edge overshoot. Previous research at the Rochester Institute of Technology's Digital Imaging and Remote Sensing Laboratory has resulted in a modeling methodology for sparse and segmented aperture systems, the validation of which will be the focus of this work. This methodology has predicted some unique post-processing artifacts that arise when a sparse aperture system is used over a large (panchromatic) spectral bandpass. Since these artifacts are unique to sparse aperture systems, they have not yet been observed in any real-world data. In this work, a laboratory setup and initial results for a model validation study will be presented. Initial results will focus on the validation of spatial frequency response predictions and verification of post-processing artifacts. The goal of this study is to allow the artifact predictions of this model to be used in image quality studies of non-conventional systems, such as aperture design optimization and the signal-to-noise vs. post-processing artifact tradeoff resulting from choosing a panchromatic vs. multispectral system.

9617-9, Session 2

Multiple-baseline detection of a geostationary satellite with the Navy precision optical interferometer

J. Tom Armstrong, Ellyn K. Baines, Henrique R. Schmitt, Sergio R. Restaino, James H. Clark, U.S. Naval Research Lab. (United States); James A. Benson, Donald J. Hutter, Bob T. Zavala, U.S. Naval Observatory (United States)

Using the Navy Precision Optical Interferometer (NPOI), we have made the first multiple-baseline interferometric detection of a satellite.

The observations, carried out during the March 2015 glint season, succeeded in detecting the DirecTV-7S satellite with interferometer baseline lengths of 8.8 m and 9.8 m and wavelengths from 850 nm to 550 nm, corresponding to a resolution of ~0.02 arcsec, or 4 m at geostationary altitude. This is the first multiple-baseline interferometric detection of a satellite.

9617-10, Session 3

Spectrum engineering for ultrafast imaging

Eric Huang, Qian Ma, Zhaowei Liu, Univ. of California, San Diego (United States)

Conventional imaging techniques use arrays of light detectors to capture an image. However, in order to record the image, each of these detectors must be read electronically. As a result, the ultimate imaging speed of a conventional camera is usually limited to the electronic bandwidth of the readout circuit, which is often too slow to view many processes of interest. A relatively new technique called Compressive Sensing, on the other hand, provides a method for greatly reducing the number of samples needed to take an image, potentially offering an avenue to increase imaging speed. However, current compressive sensing methods work by sampling an image with spatial light modulators, which rely on arrays of electronically controlled optical modulators that are often many orders of magnitude slower than the light detectors used to measure them. Here, we show an experimental demonstration of a method which uses devices with a recently developed ultrafast spatial light modulator that can reach frame rates in the megahertz range. This method can also be applicable to nanoscale structures for the combination of both high-speed and high-resolution imaging.

9617-11, Session 3

Remote sensing solution using 3-D flash LADAR for automated control of aircraft

Brian J. Neff, U.S. Air Force (United States)

Laser Radar imagers known as FLASH LADAR sensors can be designed to provide 2-D and 3-D images of a scene in a single pulse from the laser illuminator. For 3-D sensors, the benefit of having range and intensity for every pixel in the image is obvious, and there are numerous civilian and military applications of interest. This effort will present test results from a 3-D FLASH Laser Radar (LADAR) imaging system flown onboard a small cargo aircraft. The imaging system will be used to image both airborne and ground based targets to demonstrate the utility of 3-D FLASH LADAR for a variety of missions. Previous research employing scanning LADAR for airborne targets yielded disappointing results. However, scanning LADAR is not optimized for imaging environments where both the host platform and target are moving independent of each other. This work will demonstrate that 3-D FLASH LADAR is optimized for this imaging environment, as range and orientation can simultaneously be determined with great precision. Being able to determine range and orientation will be imperative for tasks such as automated aerial refueling. Additionally, images of ground based targets of interest will be collected for analysis and

development of techniques for various missions such as utility line surveys and automated landing of aircraft. Finally, this work seeks to gather and make publicly available a large collection of images for further development and advancement of the technology.

9617-12, Session 3

Experimental method of generating electromagnetic Gaussian Schell-model beams

Matthew J. Gridley, Milo W. Hyde IV, Air Force Institute of Technology (United States); Mark F. Spencer, Air Force Research Lab. (United States); Santasri Basu, Air Force Institute of Technology (United States)

The purpose of this research effort is to experimentally generate an electromagnetic Gaussian Schell-model beam from two coherent linearly polarized plane waves. The approach uses a sequence of mutually correlated random phase screens on phase-only liquid crystal spatial light modulators at the source plane. The phase screens are generated using a published relationship between the screen parameters and the desired electromagnetic Gaussian Schell-model source parameters. The approach is verified by comparing the experimental results with published theory and numerical simulation results. This work enables the design of an electromagnetic Gaussian Schell-model source with prescribed coherence and polarization properties.

Laser beam propagation and wavefront correction in turbid media

Alexis V. Kudryashov, Ilya Galaktionov, Julia Sheldakova, Active Optics Night N Ltd. (Russian Federation)

No Abstract Available

9617-14, Session 4

Transparent-conductor/oxide/silicon plasmonic photocapacitor for spectral imaging

Farnood Khalilzadeh-Rezaie, Christian W. Smith, Michael S. Lodge, Janardan Nath, Univ. of Central Florida (United States); Justin W. Cleary, Air Force Research Lab. (United States); Masahiro Ishigami, Robert E. Peale, Univ. of Central Florida (United States)

We demonstrate a single pixel of a potential compact spectral imager based on electronic detection of surface plasmon polaritons (SPPs). The technology exploits the angle- and wavelength-dependent excitation of SPPs on one surface of a Kretschmann prism coupler to generate the necessary spectral selection. The SPPs are then detected by a close-coupled transparent-conductor/silicon-oxide/silicon photocapacitor. The transparent conductor, which so far has been graphene or thin gold, is used to detect and control photo-generated charge accumulation at the Si/SiO2 interface. A small negative bias applied on the transparent conductor extinguishes the response. The resulting device potentially enables an ultra compact spectral imager. Though this demonstration is made at visible wavelengths, the method is readily extendable to infrared and even mm-waves.

9617-15, Session 4

Light field modulation of computational ghost imaging with defocus blur

Weiliang Zhang, Wenwen Zhang, Qian Chen, Guohua Gu, Nanjing Univ. of Science and Technology (China)

In recent years, as a new imaging method, ghost imaging has many features that are not included in conventional imaging. The main advantage is the ability to resist the atmospheric turbulence effect partially and separate object from image. Computational ghost imaging eliminates the need for experimental aspects of the reference arm and calculates the virtual reference field by Huygens - Fresnel diffraction theory. It has been emphasized in many papers that the distance between the reference arm and the measuring arm must be consistent. However, we cannot confirm the distance between the object and light source in advance, which often leads to defocus blur effect of the final reconstructed image. In order to solve this problem, we put forward secondary computational ghost imaging based on light field modulation.

The spatial distribution of beam produced by the light source does not need to be measured and recorded by additional detectors (CCD), and the beam is directly modulated by spatial light modulator (SLM). Firstly, we use the low resolution stochastic matrix to modulate the light field and obtain a severely blurred image in accordance with the correlated imaging algorithm. Then we use the high resolution stochastic matrix for further modulation by setting the weighting ratio of the blurred image. The final reconstructed images not only suppress the defocus blur, but also improve the ability of anti-atmospheric turbulence. Further studies have shown that defocus blur of three-dimensional objects still can be eliminated by our method.
